THE NEW ROYAL
ENCYCLOPÆDIA;
OR, COMPLETE MODERN UNIVERSAL
DICTIONARY
OF
ARTS and SCIENCES,
ON A NEW AND IMPROVED PLAN.

IN WHICH ALL THE
RESPECTIVE SCIENCES,
ARE ARRANGED INTO
COMPLETE SYSTEMS,
AND THE ARTS DIGESTED INTO
DISTINCT TREATISES.
ALSO
THE DETACHED PARTS OF KNOWLEDGE
Alphabetically arranged and copiouſly explained, according to the BEST AUTHORITIES.
Containing a Digeſt and Diſplay of the
Whole Theory and Practice of the Liberal and Mechanical ARTS.
Comprizing a General REPOSITORY of
ANCIENT AND MODERN LITERATURE,
FROM THE EARLIEST AGES, DOWN TO THE PRESENT TIME:
Including all the New IMPROVEMENTS and lateſt DISCOVERIES made in the ARTS and SCIENCES, particularly

The Superfluities which abound in other Dictionaries are expunged, for the Purpoſe of incorporating Complete Syſtems, and Diſtinct Treatiſes,
By means of this addition and deviation from the Old Plan it comprizes
A GENERAL CIRCLE OF SCIENCE,
AND FORMS THE MOST COMPREHENSIVE
LIBRARY of UNIVERSAL KNOWLEDGE,
That was ever publiſhed in the ENGLISH LANGUAGE.
The Whole entirely freed from the Errors, Obſcurities, and Superfluities of other DICTIONARIES.
Illuſtrated with upwards of 150 Large Superb COPPER PLATES, *accurately* Deſcriptive of the Subjects to which they refer.
IN THREE VOLUMES.
VOL. II.

NON SIBI, SED PATRIÆ. CATO.

By WILLIAM HENRY HALL, ESQ. *Millman Place, Bedford Row, London.*
AND OTHER GENTLEMEN OF SCIENTIFIC KNOWLEDGE, WHOSE NAMES AND ADDRESSES APPEAR IN THE WORK.

LONDON: PRINTED FOR C. COOKE, Nº 17, PATER-NOSTER ROW; AND SOLD BY THE BOOKSELLERS OF
BATH, BRISTOL, BIRMINGHAM, CANTERBURY, CAMBRIDGE, COVENTRY, CHESTER, DERBY, EXETER,
GLOUCESTER, HEREFORD, HULL, IPSWICH, LEEDS, LIVERPOOL, LEICESTER, MANCHESTER,

DICTIONARY
OF
ARTS and SCIENCES.

D

D, THE fourth letter of the alphabet, and the third conſonant. Grammarians generally reckon D among the lingual letters, as ſuppoſing the tongue to have the principal ſhare in the pronunciation thereof; though the Abbot de Dangeau ſeems to have reaſon in making it a palate letter. The letter D is the fourth in the Hebrew, Chaldee, Samaritan, Syriac, Greek, and Latin alphabets; in the five firſt of which languages it has the ſame name, though ſomewhat differently ſpoke, *e. g.* in Hebrew and Chaldee *Daleth*, in Syriac *Doleth*, and in Greek *Delta*.

The form of our D is the ſame with that of the Latins, as appears from all the ancient medals and inſcriptions; and the Latin D is no other than the Greek Δ, rounded a little, by making it quicker and at two ſtrokes. The Δ of the Greeks, again, is borrowed from the ancient character of the Hebrew *Daleth*; which form it ſtill retains, as is ſhewn by the Jeſuit Souciet, in his Diſſertation on the Samaritan Medals.

D is alſo a numeral letter, ſignifying *five hundred*; which ariſes hence, that, in the Gothic characters, the D is half the M, which ſignifies a *thouſand*. Hence the verſe,

Litera D *velut* A *quingentos ſignificabit*.

A daſh added a-top, D̄, denotes it to ſtand for five thouſand.

Uſed as an abbreviation, it has various ſignifications: thus, D ſtands for Doctor; as, M. D. for Doctor of Medicine; D. T. Doctor of Theology; D. D. implies Doctor of Divinity, or "dono dedit;" D. D. D. is uſed for "dat, dicat, dedicat;" and D. D. D. D. for "dignum Deo donum dedit."

DAB, in ichthyology, the Engliſh name of a ſpecies of pleuronectes. See PLEURONECTES.

DACE, in ichthyology, a ſpecies of cyprinus. See CYPRINUS.

DACTYL, DACTYLUS, a foot in the Latin and Greek poetry, conſiſting of a long ſyllable, followed by two ſhort ones: as *cārmĭnĕ*. The dactyl and ſpondee are the moſt conſiderable of theſe poetical feet; as being the meaſures uſed in heroic verſe by Homer, Virgil, &c. Theſe two are of equal time, but not equal motion. The ſpondee has an even, ſtrong, and ſteady pace, like a trot; the dactyl reſembles the nimbler ſtrokes of a gallop.

DACTYLIC *Verſes*, are hexameter verſes, ending in a dactyl inſtead of a ſpondee; as ſpondaic verſes are thoſe which have a ſpondee in the fifth foot inſtead of a dactyl. An inſtance of a dactylic verſe we have in Virg. Æn. lib. vi. 33.

Bis patriæ cecidere manus: quin protinus omnia
Perlegerent oculis ——

DADO, in architecture, is by ſome writers uſed for that part in the middle of the pedeſtal of a column between its baſe and cornice. It is of a cubic form, whence it is alſo denominated dye.

DADUCHI, in antiquity, prieſts of Ceres. That goddeſs, having loſt her daughter Proſerpine, ſay mythologiſts, began to make ſearch for her at the beginning of the night. In order to do this in the dark, ſhe lighted a torch, and thus ſet forth on her travel throughout the world: for which reaſon it is, that ſhe is always ſeen repreſented with a lighted torch in her hand.

DÆMON, Δαιμων, a name the ancients gave to certain ſpirits, or genii, which they ſay appeared to men, either to do them ſervice, or to hurt them. According to the philoſophers, dæmons held a middle rank between the celeſtial gods and men on earth. It was the opinion of many, that the celeſtial divinities did not themſelves interpoſe in human affairs, but committed the entire adminiſtration of the government of this lower world to theſe ſubaltern deities. Several of the heathen philoſophers held, that there were ſeveral kinds of dæmons; that ſome of them were ſpiritual ſubſtances of a more noble origin than the human race, and that others had once been men. But thoſe dæmons that were the more immediate objects of the eſtabliſhed worſhip amongſt the ancient nations were human ſpirits, ſuch as were believed to become dæmons or deities after their departure from their bodies.

Heſiod, and other poets, who have recorded the ancient hiſtory or traditions, on which the public faith and worſhip were founded, aſſert, that the men of the golden age, who were ſuppoſed to be very good, became dæmons after death, and diſpenſers of good things to mankind. Though dæmon is often uſed, in a general ſenſe, as equivalent to a deity; and is accordingly applied to fate or fortune, or whatever elſe was regarded as a god, yet thoſe dæmons who were the more immediate objects of divine worſhip amongſt the heathens, where human ſpirits; as is ſhewn in Farmer on Miracles, chap. iii. ſect. 2. The word dæmon is uſed indifferently in a good and in a bad ſenſe. In the former ſenſe it was very commonly uſed amongſt the ancient heathens. It has been generally thought, that by dæmons we are to underſtand devils, in the Septuagint verſion of the Old Teſtament; but it has been ſhewn, that the word is in that verſion certainly applied to the ghoſts of ſuch dead men as the heathens deified, in Deut. xxxii. 17. Pſ. cvi. 37. Different orders of dæmons had different ſtations and employments aſſigned them. Good dæmons were conſidered as the authors of good to mankind; evil dæmons brought innumerable evils both upon men and beaſts.

DEMONIAC, Δαιμονιζομενος, one poſſeſſed by a dæmon. Dæmoniacs were ſuch as were thought to have a dæmon or dæmons inſpiring and actuating them, ſuſpending the faculties of their minds, and governing the members of their bodies.

We find in the New Teſtament, that what was ſaid and done by the dæmoniacs themſelves, is (in conformity to the vulgar language) very often referred to the dæmons by whom they were ſuppoſed to be inſpired and actuated. And dæmoniacs having been educated in the common opinion concerning the nature and reality of poſſeſſions, did (as it is natural to ſuppoſe they would) frequently fancy themſelves to be poſſeſſed by dæmons, or that they were dæmons themſelves, and ſpoke and acted in conformity to the apprehended ſentiments and inclinations of thoſe ſpirits. Hence their dread of Chriſt's power, and their treaties and expoſtulations with him. See Farmer's Letters in anſwer to Dr. Worthington, p. 98. and p. 139.

The peculiar ſymptoms of the dæmoniacs were certain kinds of inſanity, ſuch as the ancients could not account for by natural cauſes, and deemed to argue the ſeizure of the underſtanding by a malevolent dæmon, who inſtigated the unhappy patient to every thing that was extravagant and injurious to himſelf and others.

Among the Greeks, the Latins, the Jews, and other Eaſtern people, none were thought to be poſſeſſed whoſe underſtandings were not diſturbed. Amongſt the primitive Chriſtians alſo, reputed dæmoniacs were all mad, melancholy, or epileptic perſons; and ſuch likewiſe were all the dæmoniacs of the New Teſtament, as is ſhewn by Dr. Sykes in his Inquiry, and Farther Inquiry concerning this ſubject, and by Mr. Farmer in his Eſſay upon it, chap. ii. ſect. 5, 6. Both theſe writers have alſo taken much pains to ſhew, that the dæmons to whom poſſeſſions were referred by the ancients, were conſidered as human ſpirits.

In the tranſlation of the new teſtament in vulgar uſe, we frequently read of perſons having or being poſſeſſed by a devil or devils, and of Chriſt's caſting out devils. But the Scripture never deſcribes more than one evil ſpirit by the word devil; and never repreſents any perſons as poſſeſſed by the devil, or by devils, not even in a ſingle inſtance, notwithſtanding the great frequency with which the evangeliſts ſpeak on the ſubject of poſſeſſions. In all the inſtances in which the term devil occurs in the Engliſh tranſlation of the New Teſtament, the word is dæmons (δαιμονες, δαιμονια, δαιμονιζομενοι) and not that from whence comes the Engliſh word *devil* (διαβολος). As poſſeſſing dæmons were in the age of the goſpel univerſally regarded as human ſpirits, it is very reaſonable to ſuppoſe that the ſacred writers employ the term dæmon in reference to poſſeſſions, in the ſame ſenſe in which all other perſons did; eſpecially as they have given us no notice of their uſing the word in a new or peculiar ſenſe, and have even themſelves certainly uſed it on other occaſions to deſcribe ſuch dead men as the ſuperſtition of the heathens deified, and corrupt Chriſtians have propoſed as objects of worſhip. 1 Cor. x. 20, 21. 1 Tim. iv. 1. Rev. ix. 20.

DÆMONIACAL *Poſſeſſion*. In the ages of ignorance and ſuperſtition, the credulous part of mankind were eaſily perſuaded to believe, that maniacs and epileptics were really poſſeſſed by dæmons;

dæmons: but thoſe who conſulted their reaſon, and gained an inſight into nature, pronounced what commonly paſſed for dæmoniacal poſſeſſions, to be mere natural diſorders. Indeed the doctrine of dæmoniacal poſſeſſions is manifeſtly repugnant to the perfections of God, and to that fixed order of cauſes and effects which we diſcover in every part of nature, and particularly in the human ſyſtem.

Various expreſſions uſed by Chriſt and his apoſtles are thought by ſome to aſſert or imply the reality of poſſeſſions. We are told, that the people brought to Jeſus were ſuch as were *poſſeſſed and vexed with unclean* ſpirits; and that he *caſt out ſpirits with his word.* But perhaps theſe learned writers do not ſufficiently conſider, that the reality of poſſeſſions and diſpoſſeſſions was never taught by Chriſt and his apoſtles as a doctrine; and that they could not, with propriety, interpoſe their authority in eſtabliſhing the reality of poſſeſſions, conſidered as the ſecret cauſe of thoſe diſorders imputed to them: for the miraculous cure of theſe diſorders being a part of that evidence which was deſigned for the conviction of of unbelievers, we are to judge of the nature of the miracle in queſtion by reaſon alone, not by any authority which cannot be admitted previous to its performance.

DAFFODIL, in botany. See NARCISSUS.

DAFFODIL *Lady*. See AMARYLLIS.

DAGON, in mythology, an idol of the Philiſtines, repreſented under the figure of a man without thighs, with his body ending in the tail of a fiſh bending up backward; and covered with ſcales from the reins to the lower part of the belly. *Dagon* ſignifies *fiſh* in Hebrew.

DAGYSA, a marine animal with which the ſea abounds, not twenty leagues from the coaſt of Spain, firſt diſcovered by Mr. Banks and Dr. Solander, who to this new genus of marine animals gave the name of *dagyſa* from the likeneſs of one ſpecies of them to a gem. Several ſpecimens of them were taken, adhering together, ſometimes to the length of a yard or more, and ſhining in the water with very beautiful colours.

DAIRY, or DAIRO, in the Hiſtory of Japan, is the ſovereign pontiff of the Japaneſe; or, according to Kæmpfer, the hereditary eccleſiaſtical monarch of Japan. In effect, the empire of Japan is at preſent under two ſovereigns, viz. an eccleſiaſtical one, called the *dairo*, and a ſecular one, who bears the title of *kubo.* The laſt is the emperor, and the former the oracle of the religion of the country.

DAIRY, or DAIRY *Houſe*, where milk, butter, cheeſe, whey, &c. are made or kept. See HUSBANDRY.

DAIS, in botany, a genus of the decandria monogynia claſs: the characters of which are, that it has a four leaved involucrum, the corolla is divided into five parts, and the fruit is a ſingle ſeeded berry.

DAISY, in botany. See BELLIS.

DAM, a boundary or confinement, as to dam up, or dam out: *infra damnum ſuum*, within the bounds or limits of his property or juriſdiction.

DAMAGE, is generally taken for any hurt, or hindrance, that a man receives in his eſtate; but more particularly for a part of what the jurors are to enquire of in paſſing verdict for the plaintiff, or defendant, in a civil action, be it perſonal or real. After verdict given of the principal cauſe, they are aſked their conſciences touching coſts and damages, which contain the hindrances that the plaintiff or demandant hath ſuffered by means of the wrong done him by the defendant or tenant.

DAMASCUS *Steel*, a very fine kind of ſteel, made in ſome parts of the Levant, and particularly at Damaſcus, remarkable for its excellent temper; and uſed chiefly in making of ſword blades.

DAMASK, a ſort of ſilken ſtuff, having ſome parts raiſed above the ground, repreſenting flowers or other figures. It has its name from its being originally brought from Damaſcus, in Syria. There is alſo a ſtuff in France called the caffart damaſk, made in imitation of the true damaſk, having the woof of hair, coarſe ſilk, thread, wool, or cotton. Some have the warp of ſilk and the woof of thread; others are all thread, or all wool.

DAMASK is alſo a kind of wrought linen, made in Flanders, ſo called, becauſe its large flowers reſemble thoſe of damaſks. It is chiefly uſed for tables: a table-cloth, and a dozen of napkins are called a damaſk-ſervice.

DAMASKEENING, the art, or act, of adorning iron, ſteel, &c. by making inciſions therein, and filling them up with gold or ſilver wire; chiefly uſed in enriching ſword blades, guards, and gripes, locks of piſtols, &c. Damaſkeening is partly moſaic work, partly engraving, and partly carving; as moſaic work it conſiſts of pieces inlaid; as engraving, the metal is intended, or cut in *creux*; and as carving, gold and ſilver are wrought therein in *relievo*.

DAME was formerly a title of honour, and is ſtill uſed in the Engliſh law to denote a lady; but in common acceptation it ſignifies the miſtreſs of a family of the lower rank in the country.

DAMELOPRE, a kind of bilander uſed in Holland, for conveying merchandize from one canal to another, and contrived for commodious paſſage under the bridges.

DAMIANISTS, a branch of the ancient Acephalous Severites; who agreed with the Catholics in admitting the fourth council; but diſowned any diſtinction of perſons in the Godhead, and profeſſed one ſingle nature incapable of any difference; and yet they called God, the Father, Son, and Holy Ghoſt. They took their name from Damianus, a biſhop of Alexandria, who was originally their leader, in the ſixth century.

DAMPS, in natural hiſtory, are noxious ſteams, or exhalations, frequently found in cloſe ſubterraneous places, particularly mines, pits, and wells.

Damps, with reſpect to their nature and effects may be diſtinguiſhed into two kinds: the firſt is heavier than common air, and therefore chiefly lies at the bottom of pits and mines. It extinguiſhes flame, precipitates the lime of lime water, and is noxious, and often fatal to animals, and on this account called the *choke damp*. It is a ſpecies of fixed air, and has been deſcribed by modern writers under that name. It reſembles thoſe uninflammable vapours, that are produced by the combuſtion of inflammable bodies, as charcoal, and by fermenting and efferveſcing ſubſtances. See AEROLOGY. Definition XII. This damp is ſometimes viſible, and appears in form of a fog, as in a cavern near Pyrmont: and it hangs ſo near the ſurface, that a perſon may ſtand upright, without any other inconvenience than uncommon heat of his lower extremities, but he cannot without danger bend down his head.

Miners try the ſalubrity of the air in pits where they work, by carrying down with them a lighted candle; they ſoon diſcover the effects of the noxious vapour in its diminiſhing, and gradually extinguiſhing the flame; however they remain ſafely for ſeveral hours in pits where a candle cannot burn; but when the damp is ſo ſtrong, that not only the flame of the candle, but alſo the redneſs of the burning wick is extinguiſhed, they never venture to remain a minute, knowing that ſuch a degree of damp will be ſoon fatal to animal life.

The ſecond kind of noxious vapour, though leſs dangerous than the former, is called the fulminating, or fire damp; becauſe when touched by the flame of a candle, it takes fire, and explodes like gun powder. This is chiefly found in coal mines, and ſometimes in lead mines, as in thoſe of Mendip hills. It is lighter than common air, and therefore floats near the roof of ſubterraneous places; and miners, when it is accidentally inflamed, or when they deſignedly ſet fire to it, in order to deſtroy it, lie flat on the ground, and thus eſcape injury. This inflammable vapour may probably be produced by the decompoſition of pyritous matters, with which moſt mines, and eſpecially coal mines, abound.

In ſome of the coal pits in the neighbourhood of Mendip-hills, fire damps almoſt continually happen, ſo that great numbers have been killed, maimed, and burnt by them. The colliers however continue their work notwithſtanding, only uſing the caution of renewing their air very quick, and uſing no candles in their work but thoſe of a ſingle wick, and of ſixty or ſeventy to the pound; which notwithſtanding will give as good a light there, as others of ten or twelve to the pound in other places. They always have the caution to place even theſe behind them, and never preſent them to the breaſt of the work.

The pernicious damps in mines ſhew abundantly, that nature affords us inflammable air in ſome caſes; and we have found by experiments that art can do the ſame, and that very probably on the ſame principles with the natural. Sir James Lowther having collected the air of ſome of theſe damps in bladders, preſerved it ſo well, that, when brought up to London, it would take fire at the flame of a candle, on being let out by the orifice of a piece of tobacco pipe.

It is well known to all that are verſed in chymical experiments, that moſt metals emit a great quantity of ſulphureous vapours during the efferveſcence they undergo in the time of their ſolutions in their reſpective menſtruums. On this principle many have produced an inflammable air by art, like the natural one. It is obſerved that iron, while under ſolution with oil of vitriol, emits a very great quantity of theſe vapours, which are very ſubtile, and not eaſily condenſed. This vapour being received into bladders, in the ſame manner with the natural air of Sir James Lowther, took fire in the ſame manner, on being let out in a ſmall ſtream, and anſwered all the phenomena of the natural kind. See Syſtem of AEROLOGY.

“ Almoſt all chymiſts and metallurgiſts agree in believing, that mineral exhalations contribute to the production of metals. This opinion is ſo much more probable, that as phlogiſton is one of the principles of metals, (if it be true that theſe mineral exhalations are nothing elſe than phlogiſton), and as this principle is then in a ſtate of vapour, and conſequently much divided, perhaps reduced to its ſmalleſt integrant particles, it is then in its moſt favourable ſtate for combination: it is therefore probable, that when theſe exhalations meet earths diſpoſed to receive them, they combine more or leſs intimately with thoſe earths, according to their nature. Perhaps this is the chief operation of the grand myſtery of metalliſation.”

There is a vapour called the peas bloom damp, on account of its ſmell. It always comes in the ſummer time, and hath never been known to be mortal. The miners in the Peak of Derby fancy that it ariſes there from the multitude of red trefoil flowers, called by them honey ſuckles, with which the lime ſtone meadows of the Peak much abound; the ſmell of this gives timely notice to get out of the way.

DAMSEL, Damoisel, or Damoiseau, an appellation anciently given to all young people of genteel or noble extraction of either ſex, e. gr. to the ſons and daughters of knights, barons, and even of kings. Thus, in hiſtory, we read of the damſel Pepin, damſel Louis le Groſs, damſel Richard, prince of Wales. From the ſons of kings, the appellation paſſed to thoſe of great lords and barons; and, at length, to thoſe of gentlemen who were not yet knights.

Damsel, at preſent, is applied to all maids, or girls, not yet married; provided they be not of the loweſt claſs of people.

DANCE, or Dancing, as at preſent practiſed, may be defined, "an agreeable motion of the body, adjuſted by art to the meaſures or tune of inſtruments, or of the voice." But, according to what ſome people reckon more agreeable to the true genius of the art, dancing is "the art of expreſſing the ſentiments of the mind, or the paſſions, by meaſured ſteps or bounds that are made in cadence by regulated motions of the body, and by graceful geſtures; all performed to the ſound of muſical inſtruments, or of the voice."

There is no account of the original of the practice of dancing among mankind. It is found to exiſt among all nations whatever, even the moſt rude and barbarous; and, indeed, however much the aſſiſtance of art may be neceſſary to make any one perfect in the practice, the foundation muſt certainly lie in the mechaniſm of the human body itſelf.

The connection that there is between certain ſounds and thoſe motions of the human body called dancing, hath ſeldom or never been inquired into by philoſophers, though it is certainly a very curious ſpeculation. The power of certain ſounds not only over the human ſpecies, but even over the inanimate creation, is indeed very ſurpriſing. It is well known, that the moſt ſolid walls, nay the ground itſelf, will be found to ſhake at ſome particular notes in muſic. This ſtrongly indicates the preſence of ſome univerſally diffuſed and exceedingly elaſtic fluid, which is thrown into vibrations by the concuſſions of the atmoſphere upon it, produced by the motion of the ſounding body. If theſe concuſſions are ſo ſtrong as to make the large quantity of elaſtic fluid vibrate, that is diſperſed through a ſtone wall; or a conſiderable portion of earth, it is no wonder they ſhould have the ſame effect upon that inviſible and exceedingly ſubtile matter that pervades and ſeems to reſide in our nerves. The conſequence in both caſes is preciſely the ſame; the inanimate bodies tremulate, i. e. dance, to the ſound of the inſtrument; and the perſon who hears the ſounds, has an inclination to move his limbs in proportion to the meaſure or ſucceſſion of the muſical notes. It would ſeem, therefore, that the origin of dancing lies entirely in the mechaniſm of the nerves of the body.

Some great maſters in the art of dancing, having obſerved that muſic, which is inſeparable from it, was capable of being preſerved and conveyed by the muſical characters, imagined by analogy, that the like advantage could be procured to the compoſition of dances. Upon this plan they attempted what is called the chorography, an art which they ſuppoſe was either utterly unknown to the ancients, or not tranſmitted to us from them.

It may indeed be eaſily allowed, that the track or figure of a dance may be determined by written or engraved lines; but thoſe lines will neceſſarily appear ſo perplexing, ſo intricate, ſo difficult, if not impoſſible to ſeize, in their various relations, that they are only fit to diſguſt and diſcourage, without the poſſibility of their conveying a ſatisfactory or retainable inſtruction. Thence it is, that the article of Chorography in the French Encyclopédie is univerſally exploded as unintelligible and uſeleſs: though nothing more than an elementary indication of the art; and an explanation, ſuch as it is, of ſome of the technical terms of it.

Dancing is uſually an effect and indication of joy among moſt nations: though M. Palleprat aſſures us, that there are people in South America, who dance to ſhew their ſorrow; and it likewiſe made a part of the funeral ſolemnities of the ancients.

DANCER, *Rope*, a perſon who walks on a thick rope faſtened to two oppoſite poſts; which is preciſely what is expreſſed by the Latin word *funambulus*. But our rope dancers do more; for they not only walk, but dance and leap upon the rope. They occaſionally exhibit at Sadler's Wells in the vicinity of Iſlington, where their vaultings, and other feats, are truly extraordinary.

DANDELION, in botany, a genus of the polygamia equalis order, belonging to the ſyngeneſia claſs of plants. See Leontodon.

DANEGELT, or Dane-geld from *Dane* and *Gelt*, ſignifying in Dutch, money, an annual tax laid on our anceſtors, firſt of 1*s.* afterwards 2*s.* for every hide of land through the realm, for maintaining ſuch a number of forces as were thought ſufficient to clear the Britiſh ſeas of Daniſh pirates, which heretofore greatly annoyed our coaſts.

In the reign of Henry I. it was accounted among the king's ſtanding revenues; it was levied by king Stephen, and paid in the 1ſt, 2d, 20th, and 21ſt years of Henry II. ſoon after the name was loſt. No church or church land paid a penny to the danegelt; becauſe, as is ſet forth in ancient Saxon law, the people of England placed more confidence in the prayers of the church than in any military defence they could make. Camd. ap. Magn. Brit. p. 68.

DANIEL, or *Book of* Daniel, a canonical book of the Old Teſtament, ſo denominated from its author Daniel, who was a very extraordinary perſon, and was favoured of God, and honoured by men, beyond any who lived in his time. His propheſies concerning the coming of the Meſſiah, and the other great events of after-times, are ſo clear and explicit, that, as St. Jerom tells us, Porphyry objected to them, that thoſe which related to the kings of Syria and Egypt, chap. xi. muſt have been written after the times of Antiochus Epiphanes; whereas this prophecy was tranſlated into Greek a hundred years before his time, and the tranſlation was in the hands of the Egyptians, who had no great kindneſs for the Jews, and their religion. And thoſe prophecies foretelling the ſucceſſes of Alexander, chap. viii. 5. xi. 3. were ſhewn to Alexander by the Jews, in conſequence of which they obtained ſeveral privileges from him. Ant. lib. xi. c. 8. The ſtyle of Daniel is not ſo lofty and figurative as that of the other prophets; it is clear and conciſe, and his narrations and deſcriptions ſimple and natural: in ſhort, he writes more like a hiſtorian than a prophet.

The Jews do not reckon Daniel among the prophets; part of his book, that is, from the fourth verſe of his ſecond chapter, to the end of the ſeventh chapter, was originally written in the Chaldee language; the reaſon of which was, that in that part he treats of the Chaldean or Babyloniſh affairs: all the reſt of the books are in Hebrew. The ſix firſt chapters of the Book of Daniel are a hiſtory of the kings of Babylon, and what befel the Jews under their government. In the ſix laſt he is altogether prophetical, foretelling not only what ſhould happen to his own church and nation, but events in which foreign princes and kingdoms were concerned.

DANK, in commerce, a piece of ſilver current in Perſia, and in ſome parts of Arabia, weighing the ſixteenth part of a drachm. It is alſo a weight uſed by the Arabians to weigh jewels and drugs.

DANZETTE, in heraldry, when the teeth of a line is large.

DAPHNE, in botany, ſpurge laurel; a genus of the monogynia order, belonging to the octandria claſs of plants. There are 11 ſpecies, of which the two following are the moſt remarkable. 1. The laureola, or common ſpurge laurel, a native of the woods in many parts of England. 2. The mezereon, or ſpurge olive, a native of England, Germany, &c. and is a very ornamental ſhrub in gardens.

DAPHNELÆON, in medicine, Δαφνηλαιον (from δάφνη, the *bay tree*, and ελαιον, *oil*), laurinum or oil of bay. This is prepared of the berries, when full ripe and ready to fall off, by boiling them in water.

Laurinum has heating and mollifying virtues, opens the mouths of the veſſels (αναϛοματικην), and removes laſſitudes. It is beneficial in all nervous diſorders, pains and diſtillations of the ears; and is inferior to no other remedy in diſtempers of the kidneys, contracted from cold, the parts being anointed with it: but taken inwardly, it excites a nauſea.

DAPHNIUS, *Lapis*, in natural hiſtory, the name of a ſtone, the veins of which repreſent the grain of the wood of the bay tree.

DAPIFER, the dignity or office of grand-maſter of a prince's houſehold. This title was given by the emperor of Conſtantinople to the Czar of Ruſſia, as a teſtimony of favour. In France the like officer was inſtituted by Charlemagne, under the title of *dapiferat*; and the dignity of dapifer is ſtill ſubſiſting in Germany, the elector of Bavaria aſſuming the title of *arch-dapifer of the empire*, whoſe office is, at the coronation of the emperor, to carry the firſt diſh of meat to table, on horſe-back.

DARAPTI, in logic, a mode of ſyllogiſm in the third figure, wherein the major and minor are univerſal affirmative propoſitions, and the concluſion a particular affirmative. E. gr.

DA *Every truly religious man is virtuous.*
RA *Every truly religious man is hated by the world.*
PTI *Therefore, ſome virtuous men are hated by the world.*

DARDANARIUS, uſurer, monopoliſt; a name anciently attributed to ſuch as cauſed a ſcarcity, and dearneſs of proviſions, particularly corn, by buying and hoarding it up, to raiſe its value, and ſell it again at an extravagant rate. We have had too many modern Dardanarius's, who have attempted to cauſe artificial ſcarcities in times of the moſt luxuriant natural produce. The name Dardanarius was given from one Dardanus, who is ſaid to have made a practice of ſpoiling and deſtroying the fruits of the earth by a ſort of ſorcery. Hof. Lex. in voc.

DARII, in logic, a mode of ſyllogiſms in the firſt figure, wherein the major propoſition is an univerſal affirmative, and the minor and concluſion particular affirmatives. E. gr.

DA *They who ſpeak well of every body have many friends,*
RI *Some ſpeak well of every one.*
I *Therefore ſome have many friends.*

DARTOS, or Dartus, in anatomy, the inner coat of the ſcrotum, compoſed of a great number of muſcular fleſhy fibres: whence ſome conſider it as a cutaneous muſcle. Dr. Hunter ſays no no ſuch muſcle can be found, and Albinus takes no notice of it in his tables. The word is pure Greek, *δαρτος*, *excoriatus*, *pelle nudatus*, of *δερω*, *excorio*; probably becauſe it lies cloſe under the ſkin, or from its excoriated appearance.

DASYPUS, the Armadillo, or Tatou, in tetrapodology, a genus of quadrupeds, belonging to the order of bruta. The daſypus has neither fore-teeth nor dog-teeth; it is covered with a hard bony ſhell, interſected with diſtinct moveable zones or belts; this ſhell covers the head, the neck, the back, the flanks, and extends even to the extremity of the tail; the only parts to which it does not extend, are the throat, the breaſt, and the belly, which are covered with a whitiſh ſkin of a coarſe grain, reſembling that of a hen after the feathers are pulled off. The ſhell does not conſiſt of one entire piece, like that of the tortoiſe; but is divided into ſeparate belts, connected to each other by membranes, which enable the animal to move it, and even to roll itſelf up like a hedge-hog. The number of theſe belts does not depend on the age of the animal, as ſome have imagined; but is uniformly the ſame at all times, and ſerves to diſtinguiſh the different ſpecies. All the ſpecies of this animal were originally natives of America: they were entirely unknown to the ancients; and modern travellers mention them as peculiar to Mexico, Braſil, and the ſouthern parts of America; though ſome indeed have confounded them with two ſpecies of manis, or ſhell-lizard, which are found in the Eaſt Indies: others report that they are natives of Africa, becauſe ſome of them have been tranſported from Braſil to the coaſt of Guinea, where a few have ſince been propagated: but they were never heard of in Europe, Aſia, or Africa, till after the diſcovery of America. They are all endowed with the faculty of extending and contracting their bodies, and of rolling themſelves up like a ball, but not into ſo complete a ſphere as the hedge-hog. They are very inoffenſive animals, excepting when they get into gardens, where they devour the melons, potatoes, and other roots. They walk quickly; but can hardly be ſaid to run or leap, ſo that they ſeldom eſcape the purſuit either of men or dogs. But nature has not left them altogether defenceleſs. They dig deep holes in the earth; and ſeldom go very far from their ſubterraneous habitations: upon any alarm, they immediately go into their holes; but, when at too great a diſtance, they require but a few moments to make one. The hunters can hardly catch them by the tail before they ſink their body in the ground; where they ſtick ſo cloſe, that the tail frequently comes away and leaves the body in the earth; which obliges the hunters, when they want to take them alive and immutilated, to dilate the ſides of the hole.

When they are taken, and find that there is no reſource, they inſtantly roll themſelves up, and will not extend their bodies, unleſs they are held near a fire. When in deep holes, there is no other method of making them come out, but by forcing in ſmoke or water. They keep in their holes through the day, and ſeldom go abroad in queſt of ſubſiſtence but in the night. The hunters uſually chaſe them with ſmall dogs, which eaſily come up with them. When the dogs are near, the creatures inſtantly roll themſelves up, and in this condition the hunters carry them off. However, if they be near a precipice they often eſcape both the dogs and hunters: they roll themſelves up, and tumble down like a ball, without breaking their ſhell, or receiving any injury. The daſypus is a very fruitful animal: the female generally brings forth four young ones every month; which is the reaſon why the ſpecies are ſo numerous, notwithſtanding they are ſo much ſought after on account of the ſweetneſs of their fleſh. The Indians likewiſe make baſkets, boxes, &c, of the ſhells which cover their heads.

Linnæus enumerates ſix ſpecies of daſypus, principally diſtinguiſhed by the number of their moveable belts.

DATA, in mathematics, certain things, or quantities, ſuppoſed to be given, or known, in order, from them, to find out other things or quantities, which are unknown, or ſought for. A problem, or queſtion, generally conſiſts of two parts; *data* and *quæſita*. From the primary uſe of the word *data* in mathematics, it has been tranſplanted into other arts; as philoſophy, medicine, &c.

DATE, an addition, or appendage, in writings, acts, inſtruments, letters, &c. expreſſing the day and month of the year, when the act, or letter, was paſſed or ſigned; together with the place where the ſame wss done. The word is formed from the Latin *datum, given*, the participle of *do, I give*. In writings of importance, the date ſhould be written in words at length; dated or given at London this twenty fifth day of September, in the year of our Lord one thouſand ſeven hundred and ninety. In letters, the date is uſually in figures; London, September 25, 1790. An antedate is a falſe date, prior to the real time when the inſtrument was paſſed, or ſigned. A poſt date, is that poſterior to the real time, &c.

Blackſtone ſays, that a deed is good though it mentions no date, or hath a falſe date: or even if it hath an impoſſible date, as the 30th of February; provided the real day of its being dated or given, that is, delivered, can be proved.

Date, dactylus, the fruit of the palm-tree. See Phoenix.

DATISI, in logic, a mode of ſyllogiſms in the third figure, wherein the major is an univerſal affirmative, and the minor and concluſion are particular affirmative propoſitions. E. gr.

DA *All God's friends are kings.*
TI *Some of God's friends are poor.*
SI *Therefore, ſome poor are kings.*

DATIVE, in grammar, the third caſe in the declenſion of nouns; expreſſing the ſtate or relation of a thing, to whoſe profit or loſs ſome other thing is referred. In Engliſh, where we have properly no caſes, this relation is expreſſed by the ſign *to* or *for*.

DATURA, in botany, the thorn-apple; a genus of the monogynia order, belonging to the pentandria claſs of plants. There are ſix ſpecies. The ſtramonium, or common thorn-apple, riſes a yard high, with an erect, ſtrong, round, hollow, green ſtalk, branching luxuriantly. An ointment prepared from the leaves gives eaſe in external inflammations and in the hæmorrhoids. The ſeeds were lately recommended by Dr. Storck to be taken internally in caſes of madneſs; but they ſeem to be a very unſafe remedy. Taken even in a ſmall doſe, they bring on a delirium, and in a large one would certainly prove fatal. Cows, horſes, ſheep, and goats, refuſe to eat this plant.

DAUCUS, the Carrot; a genus of the digynia order, belonging to the pentandria claſs of plants. There are five ſpecies; but the only one which merits attention is the carota, or common carrot. This is ſo well known as to need no deſcription. There are ſeveral varieties, as the white, the orange, and the purple carrot; but of theſe the orange carrot is the moſt eſteemed. It grows longer, larger, and is commonly more handſome than the others, being often 15 or 18 inches long in the eatable part, and from two to four in diameter at top. Carrots are propagated by ſeeds, which are ſown at different ſeaſons of the year, in order to procure a ſupply of young roots for the table at all times. They were firſt introduced into England, by the Flemings, in the reign of Queen Elizabeth.

In the Syſtem of Agriculture, Sect. 13. we have taken notice of the good properties of carrots as a food for cattle. They have been greatly recommended as proper for fattening hogs; but from ſome experiments mentioned in the Georgical Eſſays, it appears, that though the bacon thus fed is of excellent quality, the feeding is conſiderably dearer than that fed with peaſe, pollard, &c. In the ſame eſſays the following experiment is mentioned by Dr. Hunter, concerning the propriety of raiſing carrots for the uſe of the diſtiller "In the month of October (1773), I took 24 buſhels of carrots. After being waſhed, topped, and tailed, I put them into a large brewing copper with four gallons of water; and covering them up with cloths to haſten the maceration, I ordered a fire to be kindled underneath, which in a ſhort time reduced the whole into a tender pulp. They were then put into a common ſcrew-preſs, and the juice taken from them; which, together with the liquor left in the copper, was run through a flannel bag. The juice was returned into the copper; and, as it was my deſign to make it into ale, I put to it a proportionable quantity of hops. The liquor was then boiled about an hour, when it acquired both the taſte and colour of wort. It was next put into a cooler, and afterwards into the working veſſel, where the yeaſt was added to it. It worked kindly, and in all reſpects was treated as ale. I allowed it to remain in the caſk about four months, when I broached it, but found it of a thick, muddy appearance. I attempted to fine it, but in vain. The taſte was by no means diſpleaſing, as it much reſembled malt liquor. My firſt intention being fruſtrated, I threw it into the ſtill, being about 40 gallons in meaſure, and by two diſtillations obtained four gallons of a clean proof-ſpirit. It had, however, contracted a flavour from the hop, which ſhould be left out when the intention is to reduce the liquor into ſpirit. From a groſs calculation I am induced to think that a good acre of carrots manufactured in this manner, will leave a profit of £.40, after deducting the landlord's rent, cultivation, diſtillation, and other incidental expences. In this calculation, I preſume that the ſpirit is worth ſix ſhillings per gallon, and not exciſed. An acre of barley will by no means produce ſo much ſpirit. A rich ſandy loam is the beſt land for carrot; which, after the crop is removed, will be in high cultivation for corn."

Attempts have alſo been made to prepare ſugar from carrots, but without ſucceſs; a thick ſyrupy matter like treacle being only obtainable. Raw carrots are given to children troubled with worms. They paſs through moſt people but little changed. A poultice made of the roots hath been found to mitigate the pain and abate the ſtench of foul and cancerous ulcers. Crickets are very fond of carrots; and are eaſily deſtroyed by making a paſte of powdered arſenic, wheat-meal, and ſcraped carrots, which muſt be placed near their habitations. By their ſtrong antiſceptic qualities, a marmalade made from carrots has alſo been found uſeful in preventing and curing the ſea ſcurvy.

DAUPHIN is a title given to the eldeſt ſon of France, and preſumptive heir of the crown; on account of the province of of Dauphiné, which in 1343 was given to Philip de Valois, on this condition, by Humbert, *dauphin* of the Viennois. The *dauphin*, in his letters patent, ſtyles himſelf, "By the grace of "God, eldeſt ſon of France, and *dauphin* of Viennois." Dauphin was anciently the title, or appellation of the prince of Viennois in France.

The immediate predeceſſor of the preſent preſumptive heir to the crown of France, or Dauphin, died June 4, 1789, aged 7 years and 9 months, of a very painful and lingering illneſs, which baffled the ſkill of the moſt able phyſicians.

DAY, according to the moſt natural and obvious ſenſe of the word, ſignifies that ſpace of time during which it continues to be light; in contradiſtinction to night, being that partition of time wherein it is dark: but the ſpace of time in which it is light, being ſomewhat vague and determinate, the time between the riſing and the ſetting of the ſun is uſually looked on as the day; and the time which lapſes from its ſetting to its riſing again, the night.

The word day is often taken in a large ſenſe, ſo as to include the night alſo; or to denote the time of a whole apparent revolution of the ſun round the earth; in which ſenſe it is called by ſome a natural day, and by others an artificial one: but, to avoid confuſion, it is uſual to call it in the former ſenſe ſimply the day, and in the latter a nychthemeron; by which term that acceptation of it is aptly denoted, as it implies both day and night. The nychthemeron is divided into twenty-four parts, called hours; which are of two ſorts, equal and unequal or temporary. See the article HOUR.

Different nations begin their day at a different hour. Thus the Egyptians began their day at midnight; from whom Hippocrates introduced that way of reckoning into aſtronomy, and Copernicus and others have followed him: but the greateſt part of aſtronomers reckon the day to begin at noon, and ſo count twenty four hours, till the noon of the next day; and not twice twelve, according to the vulgar computation. The method of beginning the day at midnight prevails alſo in Great Britain, France, Spain, and moſt parts of Europe. The Babylonians began their day at ſun-riſing; reckoning the hour immediately before its riſing again, the twenty-fourth hour of the day; from whence the hours reckoned in this way are called the Babylonic. In ſeveral parts of Germany, they begin their day at ſun ſetting, and reckon on till it ſets next day, calling that the twenty-fourth hour: theſe are generally termed Italian hours. The Jews alſo began their nychthemeron at ſun ſetting: but then they divided it into twice twelve hours, as we do; reckoning twelve for the day, be it long or ſhort, and twelve for the night; ſo that their hours continually varying with the day and night, the hours of the day were longer than thoſe of the night for one half year, and the contrary the other; from whence their hours are called temporary: thoſe at the time of the equinoxes became equal, becauſe then thoſe of the day and night are ſo. The Romans alſo reckoned their hours after this manner, as do the Turks at this day.

DAY, in law, is frequently uſed for the day of appearance in court, either originally, or upon aſſignation. We ſay, he had a day by the rolls; i. e. he had a day of appearance aſſigned him. If a fact be done in the night, you muſt ſay in law proceedings, *in nocte ejuſdem diei*. There are ſeveral return days in the terms; and if either of them happen upon a Sunday, the day following is taken inſtead of it: for Sunday is *dies non juridicus*: and ſo is Aſcenſion day in Eaſter term, St. John the Baptiſt in Trinity term, All Saints and All Souls in Michaelmas term, and the purification of the Virgin Mary in Hilary term. 2 Inſt. 264.

DAY's *Work*, in ſea language, denotes the reckoning or account of the ſhip's courſe, during twenty four hours, or between noon and noon, according to the rules of trigonometry.

DAYS *of Grace*, are thoſe granted by the court at the prayer of the defendant or plaintiff in whoſe delay it is.

DAYS *of Grace*, in commerce, are a number of days allowed by cuſtom for the payment of a bill of exchange after the ſame becomes due; i. e. after the time it was accepted for is expired. In England, three days of grace are allowed: ſo that a bill accepted, in order to be paid, e. gr. ten days after ſight, is not to be paid till thirteen days. Throughout France, they allow ten days of grace; as many at Dantzic; eight at Naples; ſix at Venice, Amſterdam, Rotterdam, and Antwerp; four at Francfort; five at Leipſic; twelve at Hamburgh; ſix in Portugal; fourteen in Spain; thirteen in Genoa, &c. Note, Sundays, and holidays are included in the number of days of grace.

DAZE, in natural hiſtory, a name given by our miners to a ſort of glittering ſtone, which often occurs in their works; and, as it is an unprofitable ſubſtance, is one of thoſe things which they call weeds. Theſe daze are generally of the poorer part of the vein. The ſhoad ſtones are many of them of this nature, and the ends of the veins degenerate again into them. Phil. Tranſ. N° 69.

DEACON, *Dæconus*, a perſon in the loweſt degree of holy orders, whoſe buſineſs is to baptize, read in the church, and aſſiſt at the celebration of the euchariſt. The word is formed from the Latin *diaconus*, of the Greek *διακονος*, *miniſter*, *ſervant*.

Deacons were firſt inſtituted, ſeven in number, by the apoſtles, Acts, chap. vi. which number was retained a long time in ſeveral churches. The office of a deacon, in the church of England, according to the form of ordination, is to baptize, preach, and aſſiſt in the adminiſtration of the Lord's ſupper; and, in ſhort, to perform all the other offices in the liturgy, which a prieſt can do, except that of conſecrating the elements of the Lord's ſupper, and pronouncing the abſolution. No perſon can be ordained a deacon under the age of twenty-three years, unleſs by a faculty or diſpenſation obtained from the archbiſhop of Canterbury: and in order to this, he muſt be provided with a title to a cure, or be a fellow or chaplain in ſome college in Cambridge or Oxford, or a maſter of arts of five years ſtanding, living at his own charge in either of the univerſities, or be admitted by the biſhop who ordains him to ſome benefice or curacy then void. Otherwiſe the ordaining biſhop ſhall maintain him, till he is preferred to ſome eccleſiaſtical living. And by ſtat. 13 and 14 Car. II. c. 4. no perſon is capable of being admitted to any benefice or eccleſiaſtical promotion, till he be ordained a prieſt; nor is a deacon capable of a donative, but is only allowed to uſe his orders as a chaplain to ſome family, a curate to ſome prieſt, or a lecturer without a title.

DEAD *Beat*, in horology, is a general term for a particular conſtruction of pallets; the firſt applied by Mr. Graham to clocks, to prevent the retrograde motion of the wheels, and to remedy the imperfections ariſing from the recoil of the common pallets. The principle of this eſcapement is the ſame as the horizontal wheel in watches, and what the French call *echapement à repos*.

DEAD *Lights*, are wooden ports made to faſten in the cabin windows, to prevent the waves from breaking into the ſhip in a high ſea.

DEAD *Reckoning*, in navigation, the judgment or eſtimation which is made of the place where a ſhip is ſituated; without any obſervation of the heavenly bodies. It is diſcovered by keeping an account of the diſtance ſhe has run by the log, and of her courſe ſteered by the compaſs; and by rectifying theſe data by the uſual allowances for drift, lee-way, &c. according to the ſhip's known trim. This reckoning, however, is always to be corrected, as often as any good obſervation of the ſun can be obtained.

DEAD *Languages*. See PHILOLOGY.

DEAFNESS, the ſtate of a perſon who wants the ſenſe of hearing; for the diſeaſe of the ear, which prevents its due reception of ſounds. Deafneſs generally ariſes either from an obſtruction, or a compreſſion, of the auditory nerve; or from ſome collection of matter in the cavities of the inner ear; or from the auditory paſſage being ſtopped up by ſome hardened excrement; or, laſtly, from ſome excreſcence; a ſwelling of the glands, or ſome foreign body introduced within it.

Thoſe born deaf are alſo dumb, as not being able to learn any language; at leaſt in the common way. However, as the eyes in ſome meaſure ſerve them for ears, they may underſtand what is ſaid by the motion of the lips, tongue, &c. of the ſpeaker; and even accuſtom themſelves to move their own, as they ſee other people do; and by this means learn to ſpeak. Thus it was that Dr. Wallis taught two young gentlemen born deaf, to know what was ſaid to them, and to return pertinent anſwers. Digby gives us another inſtance of the ſame, within his own knowledge. And there was a Swiſs phyſician living at Amſterdam, one John Conrad Amman, who effected the ſame in ſeveral children born deaf, with ſurpriſing ſucceſs. He has reduced the thing to a fixed art or method, which he has publiſhed in his Surdus Loquens, Amſtelod. 1692, and de Loquela, ibid. 1700.

In the Phil. Tranſ. N° 312, we have an account by Mr. Waller, R. S. Secr. of a man and his ſiſter, each about 50 years old, born in the ſame town with Mr. Waller, who had neither of them the leaſt ſenſe of hearing; yet both of them knew, by the motion of the lips only, whatever was ſaid to them, and would anſwer pertinently to the queſtion propoſed. It ſeems they could both hear and ſpeak when children: but loſt their ſenſe afterwards whence they retained their ſpeech, which, though uncouth, was yet intelligible. Such another inſtance is that of Mr. Goddy's daughter, miniſter of St. Gervais in Geneva, related by biſhop Burnet. "At two years old they perceived ſhe had loſt her hearing; and ever ſince, though ſhe hears great noiſes, yet hears nothing of what is ſaid to her. But by obſerving the motions of the mouth and lips of others, ſhe acquired ſo many words, that out of theſe ſhe has formed a ſort of jargon, in which ſhe can hold converſation whole days with thoſe that can ſpeak her language. She knows nothing that is ſaid to her, unleſs ſhe ſees the motion of their mouths that ſpeak to her; ſo that in the night they are obliged to light candles to ſpeak to her. One thing will appear the ſtrangeſt part of the whole narration: ſhe has a ſiſter, with whom ſhe has practiſed her language more than with any body elſe; and in the night, by laying her hand on her ſiſter's mouth, ſhe can perceive by that what ſhe ſaith, and ſo can diſcourſe with her in the dark."

It is obſervable that deaf perſons, and ſeveral others thick of hearing, hear better and more eaſily if a loud noiſe be raiſed at the time when you ſpeak to them: which is owing, no doubt, to the greater tenſion of the ear drum on that occaſion. Dr. Willis mentions a deaf woman, who, if a drum were beat in the room, could hear very clearly; ſo that her huſband hired a drummer for a ſervant, that by this means he might hold converſation with his wife. The ſame author mentions another, who, living near a ſteeple, could always hear very well if there was a ringing of three or four bells, but never elſe. See Syſtem of ANATOMY, Part VI, Sect. X.

DEAL, is a well known kind of wood, of great uſe. A very good method of ſeaſoning planks of deal and fir, is to throw them into ſalt water as ſoon as they are ſawed, and keep them there three or four days, frequently turning them. In this caſe they will be rendered much harder, by drying afterwards in the air and ſun; but neither this nor any other means yet known, will preſerve them from ſhrinking.

Deals, called Bulgendrop deals, the hundred containing ſix ſcore, pay on importation 3*l.* 8*s.* 8 $\frac{40}{100}$ and drawback 3*l.* 3*s.* the rate 12*l.* Meabro deals, ſix ſcore, pay 1*l.* 2*s.* 10$\frac{80}{100}$*d.* and drawback 1*l.* 1*s.* the rate 4*l.* Norway deals, ſix ſcore, pay 1*l.* 8*s.* 7½*d.* and drawback 1*l.* 6*s.* 3*d.* the rate of 5*l.* Spruce deals, ſix ſcore, pay 4*l.* 5*s.* 10½*d.* and drawback 3*l.* 18*s.* 9*d.* the rate 15*l.* Deals from Ruſſia, and all other countries not particularly rated, exceeding twenty feet in length, pay 4*l.* 5*s.* 10*d*½. and drawback 3*l.* 18*s.* 9*d.* the rate 15*l.* Deals from Sweden, or any other country, of twenty feet in length or under, not otherwiſe rated, the hundred and twenty, pay 1*l.* 8*s.* 7½*d.* and drawback 1*l.* 6*s.* 3*d.* the rate 5*l.* Rods of deal expand laterally, or croſs the grain, in moiſt weather, and contract again in dry; and thence have been found to make uſeful hygrometer.

DEAN, a prime dignitary in moſt cathedral and collegiate churches; being uſually the preſident of the chapter. He is called *dean*, *decanus*, of the Greek δεκα, *ten*, as being ſuppoſed to preſide over ten canons or prebendaries at leaſt.

In England, as there are two foundations of cathedral and collegiate churches, the old and the new (the latter being thoſe founded by Henry the Eighth, on the ſuppreſſion of the abbots and priors, when their convents were turned into *dean* and chapter); ſo there are two ways of creating the *deans*. Thoſe of the old foundation, as the *deans* of St. Paul's, York, &c. are raiſed to their dignity much like a biſhop; the prince firſt ſending out his conge d'eſlire to the chapter; the chapter then chooſing, the king yielding his royal aſſent, and the biſhop confirming him, and giving his mandate to inſtal him. Thoſe of the new foundation, as the *dean* of Canterbury, Durham, Ely, Norwich, Wincheſter, &c. are donative, and are inſtalled by a ſhorter courſe; only by the king's letters patent, without either election or confirmation. There are ſome cathedral churches, which never had a *dean*; as that of St. David and Landaff, where the biſhop is the head of the chapter, and in his abſence the archdeacon.

DEAN is alſo applied among us to divers perſons that are the chief of ſome peculiar churches, or chapels: as the *dean* of the King's chapel, who has no juriſdiction.

DEANERY, the office of a dean. Deaneries and prebends may become void, like a biſhoprick, by death, by deprivation, or by reſignation either to the king or biſhop. If a dean, prebendary, or other ſpiritual perſon, be made a biſhop, all the preferments of which he was before poſſeſſed are void; and the king may preſent to them, in right of his prerogative royal. But they are not void by the election, but only by the conſecration.

DEAN *and Chapter*. Anciently, biſhops did not ordinarily tranſact matters of moment *ſine conſilio preſbyterorum principalium*, who were then called *ſenatores eccleſiæ*, and colleagues of the biſhops; repreſented, in ſome meaſure, by our chapters of cathedrals, wherein the *dean* and ſome of the prebends are, upon the biſhop's ſummons, to aſſiſt him in ordinations, deprivations, condemnations, excommunications, and other weighty concerns of the church.

DEATH, *Mors*, is generally conſidered as the ſeparation of the ſoul from the body; in which ſenſe it ſtands oppoſed to life, which conſiſts in the union thereof. Phyſicians have uſually defined death by a total ſtoppage of the circulation of the blood; and a ceſſation of the animal and vital functions conſequent thereon; as reſpiration, ſenſation, &c. An animal body, by the actions inſeparable from life, undergoes a continual change: in time its ſmalleſt fibres become rigid; its minute veſſels grow into ſolid fibres no longer pervious to the fluids; its greater veſſels grow hard and narrow; and overy thing becomes contracted, cloſed, and bound up; whence the dryneſs, immobility, and extenuation, obſerved in old age. By ſuch means, the offices of the minuter veſſels are deſtroyed, and the humours ſtagnate, harden, and at length coaleſce with the ſolids: thus are the ſubtleſt fluids in the body intercepted and loſt, the concoction weakened, and the reparation prevented; only the coarſer juices continue to run ſlowly through the greater veſſels, to the preſervation of life, after many of the animal functions are deſtroyed. At length, in the proceſs of theſe changes death itſelf becomes inevitable, as the neceſſary conſequence of life. But it is rare, that life is thus long protracted, or death ſucceeds merely from the decays and impairments of old age; diſeaſes in a long and horrid train, uſually precipitate diſſolution.

Dr. Stevenſon is of opinion, that after the motion of the heart, arteries, and lungs ceaſes, there often remains a ſmall degree of vital principle, deſerving attention. After a full ſtop of all thoſe organic motions on which life is ſaid to depend, the juices frequently retain ſo much of the animal proceſs, as frequently ſerves to keep up warmth for a long time; which, with proper cheriſhing, might perhaps reſtore life entirely. Every age and country affords inſtances of ſurpriſing recoveries after lying long for dead. From the number of thoſe preſerved by lucky accidents, we may conclude a far greater number might have been preſerved by timely pains and ſkill. Med. Eſſ. Edinb. Vol. V. Art. 77.

This ingenious author hopes, from his theory, that one who from all the above mentioned motions ceaſing, may with propriety be called dead, may recover, and be properly ſaid to come to life again. His theory is, that the cauſe of animal heat, or of the inteſtine motion which has been going on proſperouſly, while the progreſſive motion of the fluids in the veſſels continued, is now checked; yet ſtill proceeds in a lower manner, perhaps like the beginning of fermentation or putrefaction. By this degree of the animal proceſs, the maſs of fluids, particularly in the great reſervoir of venous blood, the heart, rarefying, preſſing every way, and being reſiſted by the valves, ſwells ſo as to fill the flaccid right auricle of the heart, which had been ſome time empty; and thus ſtimulating its fibres, which were at reſt, puts them into motion again; as we ſee the heart, after being taken out of the body, by being pricked, or having warm water thrown on it, beats afreſh, though it has been for ſome time motionleſs. The right auricle being thus filled, and ſtimulated into a contraction, fills the ventricle: which being irritated, likewiſe contracts and empties itſelf into the pulmonary artery; whereby the circulation begins where it left off, and life is reſtored, if the organs and juices are in a fit diſpoſition for it, as they perhaps are much oftener than is imagined. From hence it ſeems, that death does not inevitably attend an entire organic reſt of what we call the fluids of the body; nay, that one cannot be called dead till the energy of the blood is ſo far gone, that, though aſſiſted by all poſſible means, it can never be again able to fill, and ſtimulate into contraction, the right *ſinus venoſus* and auricle of the heart. See a remarkable caſe, in ſupport of this opinion, in Med. Eſſ. Edinb. Vol. V. Art. 55.

The ſigns of death are in many caſes very uncertain. If we conſult what Winſlow or Brachir have ſaid on this ſubject, we ſhall be convinced, that between life and death the ſhade is ſo very undiſtinguiſhable, that even all the powers of art can ſcarcely determine where the one ends and the other begins. The colour of the viſage, the warmth of the body, and ſuppleneſs of the joints, are but uncertain ſigns of life ſtill ſubſiſting; while, on the contrary, the paleneſs of the complexion, the coldneſs of the body, the ſtiffneſs of the extremities, the ceſſation of all motion, and the total inſenſibility of the parts, are but uncertain marks of death begun. In the ſame manner alſo, with regard to the pulſe and breathing: theſe motions are often ſo kept under, that it is impoſſible to perceive them. By bringing a looking-glaſs near to the mouth of the perſon ſuppoſed to be dead, people often expect to find whether he breathes or not. But this is a very uncertain experiment: the glaſs is frequently ſullied by the vapour of the dead man's body; and often the perſon is ſtill alive, though the glaſs is no way tarniſhed. In the ſame manner, neither burning nor ſcarifying, neither noiſes in the ears nor pungent ſpirits applied to the noſtrils, give certain ſigns of the continuance of life; and there are many inſtances of perſons who have endured them all, and afterwards recovered, without any external aſſiſtance, to the aſtoniſhment of the ſpectators. This ought to be a caution againſt haſty burials, eſpecially in caſes of ſudden death.

The law diſtinguiſhes between natural and civil death: the former is the actual termination of life: the latter, when a perſon is not actually dead, but adjudged ſo by law. Thus, if a perſon for whoſe life an eſtate is granted remains beyond ſea, or is otherwiſe abſent ſeven years, and no proof be made of his being alive, or becomes a profeſſed monk, he ſhall be accounted naturally dead. However, the latter diſability, ſince the reformation, is held to be aboliſhed.

DEATH *Watch*, in entomology, the Engliſh name of the pediculus of old wood, a ſpecies of the termes, belonging to the order of aptera and claſs of inſects in the Linnæan ſyſtem. It is nearly of the ſize of the common louſe; and the noiſe, reſembling the beating of a watch, is made by the male or female, when wooing each other. This ticking noiſe the populace have long taken for a preſage of death, in the family where it is heard.

There are two kinds of death watches: of the firſt we have a good account in the Philoſophical Tranſactions, by Mr. Allen. It is a ſmall beetle, five ſixteenths of an inch long, of a dark brown colour, ſpotted; having pellucid wings under the vagina, a large cap, or helmet, on the head, and two antennæ proceeding from beneath the eyes. The part with which it beats, he obſerved, was the extreme edge of the face, which he chooſes to call the upper lip; the mouth being protracted by this bony part, and lying underneath, out of view. Its figure, as it appears in a microſcope, ſee repreſented in Tab. Nat. Hiſt. *Fig.* 2.

This account is confirmed by Mr. Derham, with this difference, that, inſtead of ticking with the upper lip, he obſerved the inſect to draw back its mouth, and beat with its forehead. That author had two death watches, a male and female, which he kept alive in a box, ſeveral months; and could bring one of them to beat whenever he pleaſed, by imitating its beating; and by this ticking noiſe he could frequently invite the male to get up upon the other, in the way of coition. When the male found he got up in vain, he would get off again, beat very eagerly, and then up again: whence the ingenious author concludes thoſe pulſations to be the way whereby thoſe inſects woo one another, and find out, and invite each other to copulation.

The ſecond kind of death-watch is an inſect in appearance quite different from the firſt. The former only beats ſeven or eight ſtrokes at a time, and quicker: the latter will beat ſome hours together, without intermiſſion; and his ſtrokes are more leiſurely, and like the beat of a watch. This latter is a ſmall greyiſh inſect, much like a louſe when viewed with the naked eye. This inſect is at firſt a minute white egg, much ſmaller than the nits of lice; though the inſect is near as big as a louſe. In March it is hatched, and creeps about with its ſhell on. When it firſt leaves its ſhell, it is even ſmaller than its egg; though that is ſcarce diſcernible without a miſcroſcope. In this ſtate it is ſomewhat like the mites in cheeſe: from this ſmall ſtate they grow gradually to their mature or perfect ſize: when they become like the old one, they at firſt run about much more ſwiftly than before. Philoſoph. Tranſ. abr. vol. v. p. 26. &c.

DEBENTURE, a term of trade uſed at the cuſtom-houſe for a kind of certificate ſigned by the officers of the cuſtoms, which entitles a merchant exporting goods to the receipt of a bounty or draw back. All merchandizes that are deſigned to be taken on board for that voyage being entered and ſhipped, and the ſhip being regularly cleared out, and ſailed out of port on her intended voyage, debentures may be made out from the exporter's entries, in order to obtain the drawbacks, allowances, bounties, or premiums; which debentures for foreign goods are to be paid within one month after demand. And in making out theſe debentures, it muſt be obſerved, that every piece of vellum, parchment, or paper, containing any debentures for drawing back cuſtoms or duties, muſt, before writing, be ſtamped, and pay a duty of eight pence. The form of debentures varies, according to the merchandiſe exported. In debentures for foreign goods, no perſon may be admitted to ſwear to the exportation, but the true exporter, either as a proprietor, or who being employed by commiſſion, is concerned in the direction of the voyage. All kinds of debentures, before delivered or paid to the exporters, are entered into a ſeparate book kept for that purpoſe by the collector or comptroller of the cuſtoms.

DEBET, among merchants, ſignifies the ſums due to them for goods ſold on credit, for which they have charged their journal or ledger. Among book keepers, it is uſed to expreſs the left hand page of the ledger, to which are carried all articles ſupplied or paid, on the ſubject of an account.

DEBILITY, in a medicinal ſenſe, is a relaxtion of the ſolids, which often induces weakneſs and fainting.

DEBRUISED, in heraldry, a term peculiar to the Engliſh, by which is intimated the grievous reſtraint of any animal, debarred of its natural freedom, by any of the ordinaries being laid over it. Thus when a pale, &c. is borne upon a beaſt in an eſcutcheon, the beaſt is ſaid to be debruiſed by the pale.

DEBT, a thing due to another, whether it conſiſt of money, goods, or ſervices. The legal acceptation of debt is a ſum of money due by certain and expreſs agreement: as, by a bond for a determinate ſum; a bill or note; a ſpecial bargain; or a rent reſerved on a leaſe, that is fixed and unalterable. We meet with divers kinds of debts: *active debts*, are thoſe whereof a perſon is creditor; *paſſive debts*, thoſe whereof he is debtor. There are alſo *real debts*, *perſonal debts*, and *mixed debts*. It behoves an executor or adminiſtrator to pay regard to the priority of debets in diſcharging them; otherwiſe, on deficiency of aſſets, he muſt anſwer thoſe of a higher nature out of his own eſtate: ſuch are funeral charges, and expence of proving the will; debts to the king on record or ſpecialty; debts, which by particular ſtatutes are to be preferred to all others, as forfeiture for not burying in woollen, money due on poor's rates, letters to the poſt office, and ſome others; debts of record, as judgments, ſtatutes, and recognizances; debts due on ſpecial contracts, as for rent, on bonds, covenants, &c. under ſeal; and laſtly, debts on ſimple contracts, as notes and verbal promiſes, and ſervant's wages.

Debt, *National*. See Fund.

DEBTOR, a perſon who owes ſomething to another: in oppoſition to creditor, which is he to whom it is owing.

DECAGON, a plain figure in geometry, having ten ſides and angles. If all the ſides and angles be equal, it is called a regular decagon, and may be inſcribed in a circle. A fortification conſiſting of ten baſtions, is ſometimes called a decagon.

DECAGYNIA, (from δεκα, *ten*, and γυνη, a *woman*;) the name of the fifth order, or ſecondary diviſion, in the tenth claſs decandria, of the ſexual method, conſiſting of plants, whoſe flowers are furniſhed with ten ſtamina and the ſame number of ſtyles; which laſt are conſidered by Linnæus, and the ſexualiſts, as the female organs of generation in plants. Neurada, and American night ſhade, furniſh examples. See Claſs X. Order V. in Syſtem of Botany, and Plate IV.

DECALOGUE, the ten commandments of God, engraven on two tables of ſtone and given to Moſes, the word is Greek, compoſed of δεκα, *ten*, and λογος, *word*, *ten words*. Accordingly, the Jews call them עשרה הדברים, *the ten words*, which appellation is very ancient. Though both Jews and Chriſtians agree in the number of ten commandments, there is ſome difference as to the manner of dividing them.

The Talmudiſts, and Poſtellus after them, in his treatiſe De Phoenicum Literis, ſay, that the Decalogue, or ten commandments, were engraven quite through the tables which God gave to Moſes; but that nevertheleſs the middle of the ם *Mem* final, and and ס *Samech*, remained miraculouſly ſuſpended without adhering to any thing. See the diſſertation on the Samaritan medals, printed at Paris in 1715. They add, that the Decalogue was written in letters of light, i. e. in luminous ſhining letters.

The Decalogue was originally delivered in two tables; one of which contains our duty to God, expreſſed in the four firſt commandments; and the ſecond, our duty to our neighbour, enforced in the ſix laſt. The church of Rome, for a very obvious reaſon, hath omitted the ſecond commandment in many of her books; and in order to preſerve the number complete, divided the laſt into two.

DECAMP. When an army raiſes its camp, or breaks up from the place where it lay before, they ſay it is decamped.

DECANDRIA, (δεκα, *ten*, and ανηρ, a *huſband*) Linnæus's tenth claſs, comprehending thoſe hermaphrodite plants which bear flowers with ten ſtamina. Of this claſs of plants there are five orders; viz. the monogynia, containing fifty three genera; the digynia, comprehending twelve genera; the trigynia, eleven; the pentagynia, fourteen; and the decagynia, two genera. See Claſs 10, in Syſtem of Botany, and Plate IV.

DECANTATION, in chymiſtry, the act of pouring off a liquor from the fæces, &c. by gently inclining the lip, or canthus of the veſſel; whence the word is derived. See Canthus.

DECEIT, in law, a ſubtle trick, or device, to which may be added all manner of craft and colluſion, or underhand practice, uſed to defraud another, by any means whatever.

DECEMBER, the laſt month of the year, conſiſting of thirty one days; and ſo called as being the tenth month in the Roman year, which commenced with March.

DECEM-TALES, in law, a writ that iſſues directed to the ſheriff, whereby he is commanded to make a ſupply of jurymen, when a ſufficient number does not appear on a trial at bar.

DECEMVIRI, in Roman antiquity, ten magiſtrates choſen annually at Rome, to govern the commonwealth inſtead of conſuls, with an abſolute power to draw up and make laws for the people.

One of the decemvirs had all the enſigns and honours of the function, and the reſt had the like in their turn, during the year of their decemvirate. In them was veſted all the legiſlative authority ever enjoyed by the kings, or, after them, by the conſuls. It was the decemviri that drew up the laws of the twelve tables, thence called *leges decemvirales*, which were the whole of the Roman law for a conſiderable time.

DECHAUSEE', in heraldry, a beaſt diſmembered at all his joints, but not removed from their places.

DECIDUOUS, an appellation chiefly uſed in reſpect to plants: thus, the calix or cup of a flower is ſaid to be deciduous, when it falls along with the flower petals; and, on the contrary, it is called permanent, when it remains after they are fallen. Again, deciduous leaves are thoſe which fall in autumn; in contradiſtinction to thoſe of the ever greens, which remain all the winter.

DECIL, *Decilis*, in aſtronomy, an aſpect or poſition of two planets, when they are diſtant from each other a tenth part of the zodiac, i. e. thirty ſix degrees.

DECIMAL *Arithmetic*, the art of computing by decimal fractions. See the Syſtem of Arithmetic, Article XII.

DECIPHERING, or Decyphering, the art, or act, of finding the alphabet of a cipher, or of explaining a letter written in cipher. Every language has peculiar rules of deciphering: which depend not only on the form of its characters, but likewiſe on the place, order, combination, frequency, and number of the letters. The curious, who deſire farther information on this ſubject, may conſult the art of deciphering deduced from principles, and explained by examples in the German, Dutch, Latin, Engliſh, French, Italian, and Greek languages, by David Arnold Conradus, in the twelfth volume of the Gentleman's Mag. for 1742. See alſo M. s'Graveſande Introd. ad Philoſophiam, cap. xxxv. Leyden, 1737. B. Porta publiſhed a treatiſe on this ſubject; and a collection of letters written in cipher, and deciphered by Dr. Wallis, are now in the library of Oxford.

DECK *of a Ship*, from decker, Dan. *to cover*; a kind of planked floor, connecting the ſides, and ſerving as different platforms to ſupport the artillery, to lodge the men, and to preſerve the cargo.

Half Deck, is a ſpace under the quarter deck of a ſhip of war, between the foremoſt bulk head of the ſteerage, and the fore part of the quarter deck. In the Northumberland colliers, the ſteerage is called the half deck, and is uſually the habitation of the ſhip's crew.

DECLAMATION, a diſcourſe or ſpeech made in public, in the tone and manner of an oration. Among the Greeks, declamation was the art of ſpeaking indifferently on all ſubjects, and on all ſides of a queſtion; of making a thing appear juſt that was unjuſt; and of triumphing over the beſt and ſoundeſt reaſons. Such ſort of declamations, M. de St. Evremond obſerves, were only fit to corrupt the mind, by accuſtoming men, to cultivate their imagination, rather than to form their judgment, and to ſeek for veriſimilitudes to impoſe upon, rather than ſolid reaſons to convince the underſtanding. Among us, declamation is reſtrained to certain exerciſes, which ſcholars perform, to teach them to ſpeak in public.

In the Britiſh ſenate there have been ſome very diſtinguiſhed ſpecimens of the powers of declamation. Even Voltaire has been candid enough to acknowledge, that the ſenatorial orators, in the time of Lord Chatham's adminiſtration, were equal to thoſe of Greece and Rome.

DECLARATION, in the cuſtom houſe and commerce of France, contains a particular account or invoice of what is contained in the bales or caſes, brought to the officer for entrance inward or outward.

Declaration, in law, the act of ſhewing in writing the cauſe of complaint of the demandant, or plaintiff, againſt the defendant, where he is ſuppoſed to have received ſome wrong.

Declaration *of Fidelity*, is uſed for a confeſſion, which the Quakers, who ſcruple taking the oaths of ſupremacy, &c. are obliged to make and ſubſcribe in lieu thereof. Its tenor is a ſolemn promiſe to be true and faithful to king George; with a deteſtation and horror of that damnable poſition, that princes excommunicated by the pope, or any other power, may be depoſed or murdered; and a declaration, that no foreign prince, or power, has any right, juriſdiction, or authority, in this kingdom.

There is alſo a declaration againſt tranſubſtantiation made and ſubſcribed by thoſe who qualify for offices; and a declaration againſt popery to be made and ſubſcribed by the members of both houſes of parliament, by diſſenters qualified according to the toleration act, &c. &c.

DECLARATORY *Part of a Law*, is that by which the rights to be obſerved, and the wrongs to be avoided, are clearly defined and laid down. This depends not ſo much on the law of revelation or of nature, as on the wiſdom and will of the legiſlator.

DECLENSION, in grammar, the inflexion of a noun, according to its diverſe caſes. See Grammar.

DECLINATION, in aſtronomy, the diſtance of the ſun, a ſtar, planet, or other point of the ſphere of the world, from the equator, either northward, or ſouthward. It is the ſame with Latitude in geography. See Syſtem of Astronomy. Sect. VIII.

Circle of **Declination**, is a great circle of the ſphere paſſing through the poles of the world; and on which the declination of a ſtar is meaſured.

Parallax of **Declination**, is an arch of the circle of declination, whereby the parallax of the altitude increaſes or diminiſhes the declination of a ſtar.

Refraction of the **Declination**, an arch of the circle of declination, whereby the declination of a ſtar is increaſed or diminiſhed by means of the refraction.

Declination *of a Vertical Plane*, or *Wall*, in dialling, is an arch of the horizon, comprehended either between the plane and the prime vertical circle, if you account it from eaſt to weſt; or between the meridian and the plane, if you account it from north to ſouth.

DECLINATOR, or **Declinatory**, an inſtrument in dialling, whereby the declination, inclination, and reclination of planes is determined.

DECLINERS, or **Declining** *Dials*, are thoſe which cut either the plane of the prime vertical circle, or the plane of the horizon, obliquely.

DECOCTION, the act of boiling any ſubſtance in water, to extract the virtues out of the ſame for ſome medicinal purpoſe; or the water itſelf, in which the ſubſtance has been boiled. Decoction is moſtly employed about balſamics, detergents, and cathartics; for it is not ſo proper for cephalics, &c. as it exhales the more volatile parts, in which the virtues of all thoſe ingredients conſiſt. The harder bodies, as woods, dried roots, &c. require moſt boiling; but herbs and ſeeds need only be ſcalded. All thoſe decoctions which are reſtringent, and moſt of the cathartics, may for the greater elegance be clarified: but all ſuch as are emollient, and intended to conſiſt of the ſoft and mucilaginous parts of ſimples, are by no means to be ſo managed.

DECOMPOSITION, in chymiſtry and pharmacy, the ſame with analyſis or reſolution; viz. the reduction of a body into its principles, or component parts.

Decomposition is ſometimes taken for any ſort of reſolution, or ſeparation of parts; but, in propriety, decompoſition is a chymical proceſs, in order to a ſeparation of the heterogeneities, or impurities, from any matter.

Decomposition is uſed by Boyle, Newton, and other Engliſh authors, to ſignify the compoſition or junction of two or more bodies, which were previouſly compounded of other parts.

DECORATION, in architecture, any thing that adorns and enriches a building, church, triumphal arch, or the like.

Decoration, is more properly applied to the ſcenes of theatres, which muſt be frequently changed, conformably to the ſubject.

DECORTICATION, the act of peeling, or unhuſking roots, ſeeds, fruits, branches, &c. or of freeing them from their barks, rinds, huſks, or ſhells.

DECOUPLE, in heraldry, the ſame as uncoupled, i. e. parted, or ſevered. Thus, a chevron *decouplé* is a chevron wanting ſo much towards the point, that the two ends ſtand at a diſtance from each other.

DECOY, a place made for catching of wild fowl. Hence alſo a decoy-duck is one that flies abroad, and lights into company of wild ones, and, being become acquainted with them, by her allurement draws them into the decoy place, where they become a prey.

The decoy is uſually made where there is a large pond, ſurrounded with wood, and behind it a marſhy and uncultivated country, where the wild-fowl may ſecurely ſleep during the daytime. The decoy conſiſts of ſeveral pipes, as they are called, which lead up a narrow ditch, that cloſes at laſt with a funnelnut. Over theſe pipes, which become narrow from the firſt entrance, is fixed a continued arch of netting ſuſpended on hoops. There is uſually a pipe or ditch for almoſt every wind that can blow, as the wild-fowl are determined by this circumſtance which pipe to chooſe; and the decoy man always keeps on the leeward ſide of the ducks to prevent his effluvia from reaching their ſagacious noſtrils. Skreens made of reeds are placed at certain diſtances along each pipe, in ſuch a manner, that it is impoſſible for the wild-fowl to ſee the decoy man, before they have paſſed towards the end of the pipe where the net is fixed. In the evening, when the wild-fowl begins to feed, the decoy riſes, and the noiſe of their wings, in their flight, may be heard at a great diſtance. The riſing of the decoy is in Somerſetſhire called *rodding*. The decoy-ducks are fed with hemp-ſeed, which is thrown in ſmall quantities over the ſkreens, to bring them forwards into the pipes, and to allure the wild-fowl to follow. They are ſo trained as to lead the way, after hearing the whiſtle of the decoy man, and enticed by the hemp-ſeed, and to dive under water, whilſt the wild-fowl fly on, and are taken in the net. When they are in ſuch a ſleepy ſtate as not to follow the decoy ducks, a ſmall dog is made to paſs between the ſkreens, approaching gradually nearer and nearer to to the purſe-net; which draws the attention of the wild-fowl, and makes them advance forward; at length the decoy man appears behind a ſkreen, and drives them into the net.

The general ſeaſon for catching wild fowl in decoys is from the latter end of October till February. The act of 10 Geo. II. cap. 32. forbids taking them from June 1. to Oct. 11. under a penalty of five ſhillings for every bird deſtroyed within that time.

The Lincolnſhire decoys are commonly ſet at a certain annual rent, from 15 to 20 pounds a year: and there is one in Somerſetſhire that pays 30l. The former contribute principally to ſupply the markets in London. Amazing numbers of ducks, wigeons, and teal, are taken: by an account of the number caught a few winters paſt, in one ſeaſon, and in only ten decoys, in the neighbourhood of Wain-fleet, it appeared to amount to 31,200, in which are included ſeveral other ſpecies of ducks: it is alſo to be obſerved, that, in the above particular, wigeon and teal are reckoned but as one, and conſequently ſell but at half price of the ducks. Pennant's Zoology, Vol. II. p. 594.

DECREES *of Council*, are the laws made by them, to regulate the doctrine and policy of the church.

Decrees *in Chancery*, are the determination of the lord chancellor, upon a full hearing of a cauſe.

DECREET, in the law of Scotland, a final decree or judgment of the lords of ſeſſion, from which an appeal only lies to parliament.

Decreet-*Arbitral*, in Scots law, the ſentence or judgment of one to whom parties voluntarily ſubmit the determination of any queſtion betwixt them.

DECREMENT, in heraldry, ſignifies the wane of the moon from the full to the new. The moon in this ſtate is called *moon decreſcent*, or in *decours*; and when borne in coat-armour, faced to the left ſide of the eſcutcheon, as ſhe does to the right ſide when in the increment.

DECREPITATION, in chymiſtry, the operation of drying and calcining ſalts over the fire, continuing till ſuch time as they ceaſe to crackle.

Decripitation is alſo applied to the noiſe or crackling of the ſalts during the operation.

DECREPITUDE, in medicine, the conſequence of the infirmities of old age: which by degrees leads to death.

DECRETAL, in the canon law, a letter of a pope determining ſome point or queſtion in the eccleſiaſtical law. The decretals compoſe the ſecond part of the canon law. Gratian publiſhed a collection of decretals, containing all the ordinances made by the popes till the year 1150. Gregory IX. in 1227, following the example of Theodoſius and Juſtinian, formed a conſtitution of his own, collecting into one body all the deciſions and all the cauſes which ſerved to advance the papal power; which collection of decretals was called the *Pentateuch*, becauſe it contains five books.

DECUPLE, in arithmetic, a term of relation, or proportion, implying a thing to be ten times as much as another.

DECURY, ten perſons ranged under one chief, or leader, called the *Decurio*. The Roman cavalry was divided into decuries, which were ſubdiviſions of a century, each century containing ten decuries.

DECUSSATION, a term in geometry, optics, and anatomy, ſignifying the croſſing of two lines, rays, or nerves, when they meet in a point, and then go on ſeparately from one another.

DECUSSORIUM, a ſurgeon's inſtrument, wherewith the *dura mater* is preſſed down in trepanning to ſecure it from damage in operation.

DEDICATION, the act of conſecrating a temple, altar, ſtatue, place, &c. to the honour of ſome deity. The uſe of dedications is very ancient, both among the worſhippers of the true God, and among the heathens: the Hebrews call it חנכה, *bhanuahah*, *initiation*; which the Greek tranſlators render εγκαινια, and εγκαινισμος, *renewing*. In the ſcripture we meet with *dedications* of the tabernacle, of altars, of the firſt and ſecond temple, and even the houſes of private perſons. Numb. vii. 10, 11, 84, 88. Deut. xx. 5. 1 Kings viii. 63. 2 Chron. vii. 5, 9. Ezra vi. 16, 17. 1 Eſd. vii. 7. Pſalm xxx. 1. Heb. ix. 18. There are alſo *dedications* of veſſels and garments of the prieſts and Levites, and even of the men themſelves. Under the Chriſtian diſpenſation, we call the like ceremonies *conſecrations*, *benedictions*, *ordinations*, &c. and not dedications, which is only applied to places, as to church; and is properly the conſecration thereof performed by a biſhop, and a number of ceremonies preſcribed by the church. The cuſtom is ſtill retained in diverſe places, under the name of *feaſts*, *wakes*, or *vigils*. The Jews celebrated the anniverſary of the dedication of their temple every year, for eight days; this was firſt enjoined by Judas Maccabæus, and the whole ſynagogue, in the year of the Syro-Macedonian æra 148, i. e. 165 years before Chriſt, on occaſion of the victory obtained by the Maccabees over the Greeks. It began every year on the twenty-fifth day of Ciſleu, and was continued to the eighth day, during all which time they illuminated their houſes, by ſetting up candles at every man's door, whence it was called the feaſt of lights. This feſtival Chriſt honoured with his preſence at Jeruſalem. John x. 22. Leo of Modena ſays, that they begun with one lamp, and added to the number, according to the day of the feaſt; ſo that on the laſt day they had eight lamps in their houſes.

The heathens had alſo dedications of temples, altars, and images of their gods, &c. Nebuchadnezzar had a ſolemn dedication of his ſtatue, Daniel iii. 2. Pilate dedicated gilt bucklers at Jeruſalem, to Tiberius; Philo de Legat. Petronius would have dedicated a ſtatue to the emperor in the ſame city, ibid. p. 791. Tacitus, Hiſt. lib. iv. cap. 53. mentions the dedication of the Capitol upon rebuilding it by Veſpaſian, &c. The heathen temples were dedicated with many ceremonies, the principal of which were the following. The pontiffs and people encompaſſed the temple with garlands and feſtoons of flowers; the veſtal virgins, holding branches of olive-trees in their hands, ſprinkled the outſide of the temple with the luſtral water; then the perſon who conſecrated, being the prætor, cenſor, &c. drew near the gate with a pontiff at his ſide, who directed him in pronouncing the words of conſecration; after which they ſacrificed a beaſt in the courts of the temple.

DEDICATION, in literature, is an addreſs prefixed to a book, ſoliciting patronage, or teſtifying reſpect for the perſon to whom it was made. The dedication of the fourth part of Mr. Edwards's Hiſtory of Birds is curious: *To* GOD *! the* ONE *eternal! the incomprehenſible! the omnipreſent! omniſcient and Almighty Creator of all things that exiſt! from orbs immeaſurably great, to the minuteſt points of matter, this* ATOM *is dedicated and devoted, with all poſſible gratitude, humiliation, and worſhip, and the higheſt adoration both of body and mind, by his moſt reſigned, low, and humble creature*, G. E.

DEDUCTION, in commerce, a ſubtracting, or retrenching, a little ſum paid, from a greater remaining to pay.

DEDUCTION, in logic and ſcience, denotes a proceſs or chain of reaſoning, where from principles ſuppoſed and allowed, we arrive at the truth of any propoſition.

DEDUCTIVE *Evidence*, in ethics, is derived either from the invariable properties or relations of general ideas, or from the actual, though perhaps variable, connections ſubſiſting among things. The former is called *demonſtrative*, and the latter *moral*.

DEED, in law, an inſtrument written on paper or parchment, comprehending ſome contract, bargain or agreement between the parties thereto, in relation to the matter therein contained.

DEEMSTERS, or **DEMSTERS**. All controverſies in the Iſle of Man are decided, without proceſs, writings, or any charges, by certain judges, choſen yearly from among themſelves, called deemſters. They ſit as judges in all courts, either for life or property; and with the advice of the twenty-four keys, declare what is law in uncommon emergencies.

DEEP *Waiſted*, in naval architecture, denotes the ſtructure of a ſhip's deck, when the quarter-deck and fore-caſtle are elevated from four to ſix feet above the level of the upper-deck, ſo as to leave a vacant ſpace, called the waiſt, on the middle of the upper-deck.

DEER, *Cervus*, in tetrapodology, the name of a genus of animals, the characters of which are, that the horns fall off every year, that they are ſolid and branched, and that the animal has eight cutting teeth in the lower jaw, and none in the upper. The word *cervus*, uſed alone, is underſtood by authors to mean the ſtag, or red-deer, the others being all diſtinguiſhed by their ſeveral adjectives; the common fallow-deer being called *cervus platyceros*, or the broad horned deer. The common deer is more preſerved in England than in any other part of the world, and carries its diſtinction from the red deer, in its ſize, and in the falcated figure of its horns. They are ſaid to have been firſt introduced here by king James I. out of Norway, who firſt brought them into Scotland, and from thence into his chaſes of Enfield and Epping. They are ſcarcely known in France, but are ſometimes found in the north of Europe. In Spain they are extremely large: they are met with in Greece, the Holy Land, and China; but, in every country except our own, are in a ſtate of nature, unconfined by man.

The method of hunting deer in the iſland of Ceylon is very particular. The huntſmen go out in the night, and only two uſually go together; the one of theſe carries upon his head an earthen veſſel, in which there is ſome fire burning and flaming; the ingredients are generally ſmall ſticks cut into pieces, and common roſin; of this the other man carries a ſupply about him to repleniſh the pot when it becomes low. The perſon who has the fire upon his head carries in one hand a ſtaff, on which there are fixed eight bells, and the larger theſe are the better. The man goes firſt into the woods, and the other follows cloſe behind, with a ſpear in his hand. As ſoon as the deer hears the noiſe of the bells, he turns toward the place whence the ſound comes, and ſeeing the fire, he eagerly runs up to it, and ſtands gazing at a ſmall diſtance; the ſecond man has then nothing to do but to kill him with the ſpear, for he ſees neither of them. Not only deer, but elks, and even hares, are thus taken; for they gaze at the fire, and never ſee the men. The profits of this ſort of hunting are very large, without any danger; for though there are great numbers of tygers, elephants, and wild boars in thoſe woods, the huntſmen are in no danger of them while the fire burns, for they all run away from it. Phil. Tranſ. N° 278. p. 1094.

Rein **DEER**, in tetrapodology, an animal very common in all the northern nations, and called by ſome authors *tarandus* and *machlis*. It is of the ſhape of a ſtag, but its body is thicker, and its whole make much more robuſt and ſtrong. The breaſt is thick, covered with very long hairs. The legs very hairy, and the hoofs moveable; for the creature expands and opens them in going; its horns are very long and finely branched. They differ from the horns of the elk in their length, and from thoſe of the ſtag or red-deer in their breadth, and from both, in the multitude of branches, and in their colour, which is white. The lower branches, which fall very near the forehead, are ſaid to be uſed by the creature to break the ice, when the waters are frozen over, that he may get drink. It feeds on ſhrubs and plants, and on the moſs which it finds on the earth, and upon the barks of trees. It is of prodigious uſe, as a beaſt of carriage, to the Laplanders; and almoſt all the other nations far north. Its horns and hoofs are of uſe in ſpaſmodic affections.

DE FACTO, ſomething actually in fact, or exiſting: in contradiſtinction to *de jure*, where a thing is only ſo in juſtice, or equity, but not in fact.

DEFAMATION, in law, the ſpeaking ſlanderous words of another; for which the ſlanderer is puniſhable, according to the nature of his offence, either by action upon the caſe at common law, or by ſtatute in the eccleſiaſtical court.

DEFAMATORY, a term chiefly uſed in the phraſe *defamatory* libel, ſignifying a writing intended to ſcandalize, or diſcredit a perſon, &c.

DEFAULT, in law, non-appearance, or an omiſſion of what a perſon ought to do, particularly before a court of juſtice, at a day aſſigned; for which judgment may be given againſt the defaulter. Jurors making default in their appearance for trying of cauſes ſhall loſe and forfeit iſſues, unleſs they have a reaſonable excuſe proved by witneſſes.

DEFEASANCE, in law (from the French *defaire*, *to defeat*), ſignifies a condition relating to a deed, which being performed the deed is defeated, and rendered void, as if it had never been made.

DEFECTIVE, or **DEFICIENT** *Nouns*, in grammar, are ſuch as want either a whole number or a particular caſe, or are totally indeclinable.

DEFENCE, in ſieges, is uſed for any thing that ſerves to preſerve or ſcreen the ſoldiers, or the place. See FORTIFICATION.

Line of **DEFENCE**, is that which flanks a baſtion, being drawn from the flank oppoſite thereto.

DEFENCE, in its true legal ſenſe, denotes an oppoſing or denial of the truth or validity of the complaint, anſwering to the *conteſtatio litis* of the civilians. It is a general aſſertion which the defendant makes immediately after the count of declaration, that the plaintiff hath no ground of action; which aſſertion is afterwards extended and maintained in his plea.

DEFENDANT, a term in law, ſignifying him who is ſued in an action perſonal; a tenant is he who is ſued in an action real.

DEFENDER *of the Faith (Fidei Defenſor)*, is a peculiar title belonging to the king of England; as Catholicus to the king of Spain; and Chriſtianiſſimus to the king of France, &c. Theſe titles were given by the popes of Rome; and that of *fidei defenſor* was firſt conferred by Leo X. on king Henry VIII. for writing againſt Martin Luther; and the bull for it bears date *quinto idus Octob.* 1521. It was afterwards confirmed by Clement VII.

Lord Herbert's Hiſt. Henry VIII. 105. But the pope, on Henry's ſuppreſſing the houſes of religion, at the time of the Reformation, not only deprived him of his title, but depoſed him from his crown alſo; though in the thirty-fifth year of his reign, this title, &c. was confirmed by parliament; and hath continued to be uſed by all ſucceeding kings to this day. Lex Conſtitutionis, 47, 48. Chamberlayne ſays, the title belonged to the kings of England before that time; and for proof hereof appeals to ſeveral charters granted to the univerſity of Oxford. So that pope Leo's bull was only a renovation of an ancient right. Pref. ſtat. lib. i. cap. 2.

DEFENDING, in fortification, is ordinarily ſynonimous with flanking. Thus we ſay the flank defends the curtin, and the oppoſite face of the baſtion; this demilune flanks, or defends, the horn, or crown-work. The ancient fortifications are eaſily taken; there being nothing to defend, that is, to flank them.

DEFENSITIVE, in medicine and ſurgery, denotes a bandage, plaſter, or the like; uſed in the cure of a wound, to moderate the violence of the pain, the flux of blood, and the acceſs, or impreſſion, of the external air.

DEFERENT, Deferens, in anatomy, is applied to certain veſſels of the body, appointed for the conveyance of humours from one place to another.

Vaſa Deferentia are two white ſolid flatted tubes, one lying on the right ſide, and the other on the left; from the epididymis, of which they are continuations; each of them runs up in the cellula vagina of the ſpermatic veſſels; as high as the openings in the abdominal muſcles, the blood veſſels lying forward, and the vas deferens behind them. Theſe veſſels convey the ſeed as faſt as it is ſecreted and prepared in the teſticles, &c. into the veſiculæ ſeminales; there to be depoſited till an emiſſion is required.

The paſſage of the *vaſa deferentia* into the *veſiculæ ſeminales* is very particular. Theſe canals are incurvated behind the bladder, and their contracted extremities unite at that place. They unite in an angle, and run between the contiguous extremities of the *veſiculæ*; and this union is ſo cloſe, that the adhering portions ſeem only to form the middle ſeptum, between two ſmall tubes; ſee Syſtem of Anatomy, Part III. Sect. II. and the Plate on the Male Organs of Generation, *Fig.* 1, 66.

Deficient *Numbers*, are ſuch whoſe parts, added together, make leſs than the integer, whoſe parts they are. Such, e. gr. is 8; whoſe quota parts are 1, 2, and 4; which together, only make 7.

DEFILE, in fortification, a narrow paſs or way through which a company of horſe, or foot, can paſs only in file, by making a ſmall front; ſo that the enemy may take an opportunity to ſtop their march, and to charge them with ſo much the more advantage, becauſe the front and rear cannot reciprocally come to the relief of one another.

DEFINITE, in grammar, is applied to an article that has a preciſe, determinate ſignification. Such are, the article *the* in Engliſh, *le* and *la* in French, &c. which fix and aſcertain the noun they belong to, to ſome particular; as, *the* king *le* roy: whereas, in the quality *of*, king, *de* roy, the articles *of*, and *de*, mark nothing preciſe; and are therefore called indefinite.

DEFINITION, in logic, an enumeration of the chief ſimple ideas, whereof a compound idea conſiſts; in order to aſcertain, or explain, its nature and character. Definitions are of two kinds; the one *nominal*, or, *of the name*: the other *real*, or, *of the thing*.

Definition *of the Name*, or, *Nominal* Definition, is that which explains the ſenſe or ſignification appropriated to a word: or, as Wolfius more accurately conſiders it, it is an enumeration of certain marks, or characters, ſufficient to diſtinguiſh the thing defined from any other thing; ſo as to leave it out of doubt, what the ſubject is that is intended, or denoted by the name. This is what is meant by definition in mathematics. Such is the definition of a ſquare, when it is ſaid to be a quadrilateral, equilateral, rectangular figure.

Definition *of a Thing*, or *Real* Definition, is properly an enumeration of the principal attributes of a thing, in order to convey or explain its nature. Thus, a circle is defined a figure, whoſe circumference is every where equidiſtant from its centre.

Definition, in rhetoric, is one of the common places, and is defined by Tully, a ſhort comprehenſive explanation of a thing.

The definitions of the orator, it muſt be obſerved, differ much from thoſe of the logician and philoſopher: theſe latter define a thing cloſely and drily by genus and difference; e. gr. man is a reaſonable animal, &c. The orators take a larger compaſs and define things more ornamentally from the places of rhetoric, thus: man is a curious work of an Almighty Creator, framed after his own image, endued with reaſon, and born for immortality. But this rhetorical definition, in ſtrictneſs, comes nearer to the nature of a deſcription, than an accurate definition.

DEFINITIVE is applied to ſomewhat that terminates or decides a queſtion, or proceſs. Thus we ſay; the houſe of lords have paſſed a definitive ſentence in ſuch a cauſe: the church has given a definitive judgment on ſuch an article of faith. The word ſtands in oppoſition to proviſional, and interlocutory.

DEFLAGRATION, in chymiſtry, the kindling, or ſetting fire to a ſalt, a mineral, or other matter, either alone, or mixed for that purpoſe, with a ſulphureous one, in order to purify it. As is done in the preparing of Æthiops mineral by fire, or ſal prunellæ, &c. The word is formed of the Latin *de*, and *flagrare*, *to burn*. This ſhort proceſs has been often recommended to the world as of great uſe in trying the ſtrength of brandies, and other vinous ſpirits, and has been greatly improved in this reſpect by Mr. Geoffroy.

The common way of trying ſpirits by deflagration, is to meaſure out any quantity of it, then to heat it, and ſet it on fire; if after it will no longer burn, the remainder is half as much as the quantity meaſured out for the trial was, then the ſpirit tried is found to conſiſt of half water, and half totally inflammable ſpirit, that is, it is exactly what we underſtand by the term perfect proof, and according as the remainder is more or leſs than half the original quantity, it is ſo much below or ſo much above proof, or the due ſtrength of brandy. See Syſtem of Chymiſtry, Part II.

DEFLECTION, the turning any thing aſide from its former courſe, by ſome adventitious or external cauſe. The word is often applied to the tendency of a ſhip from her true courſe, by reaſon of currents, &c. which divert her, and turn her out of her right way.

Deflection *of the Rays of Light*, is a property which Dr. Hooke obſerved in 1674-5, and read an account of before the Royal Society, March 18, the ſame year. He ſays, he found it different both from reflection, and refraction; and that it was made towards the ſurface of the opacous body perpendicularly. This is the ſame property which Sir Iſaac Newton calls Inflection. It is called by others Diffraction.

DEFLORATION, or Deflowering, the act of violating, or taking away a woman's virginity. Death, or marriage, are decreed by the civil law in caſe of defloration. Many anatomiſts make the hymen a real proof of virginity, perſuaded that where it is not found, the girl muſt have been deflowered. The natives of the coaſt of Malabar hold virginity in ſo little eſtimation, that they pay ſtrangers to come and deflower their brides. Among the Scots, it was a privilege of the lords of the manor, that they ſhould have the firſt night's lodging with their tenant's wives. See Culliage.

DEFLUXION, or Fluxion, a falling, or flowing of ſome humour to any part of the body; as of rheum on the trachea, and œſophagus, in a catarrh. The word is formed from the Latin *defluo*, *I flow down*, the humours falling upon ſome part, where they are gathered together. Defluxions on the lungs are of dangerous conſequence. Defluxions on the eyes produce a weakneſs of ſight, and frequently blindneſs.

DEFOLIATION (from *de*, and *folium* a leaf); the fall of the leaves. A term oppoſed to *frondeſcentia*, the annual renovation of the leaves, produced by the unfolding of the buds in ſpring.

Moſt plants in cold and temperate climates ſhed their leaves every year; this happens in autumn, and is generally announced by the flowering of the common meadow ſaffron. The term is only applied to trees and ſhrubs; for herbs periſh down to the root every year, loſing ſtem, leaves, and all. All plants do not drop their leaves at the ſame time. Among large trees, the aſh and walnut, although lateſt in unfolding, are ſooneſt diveſted of them; the latter ſeldom carries its leaves above five months.

Some trees and ſhrubs preſerve their leaves conſtantly through the whole year; and are not in the leaſt influenced by the clemency or inclemency of ſeaſons. Such are the firs, juniper, yew, cedar, cypreſs, and many other trees, hence denominated *evergreens*. Theſe preſerve their old leaves a long time after the formation of the new, and do not drop them at any determinate time.

Some herbaceous perennials, as the houſe-leeks and navelworts, enjoy the ſame privilege with the ever-green trees, and reſiſt the ſeverities of winter: ſome even can diſpenſe with the earth for ſome time; being replete with juices, which the leaves imbibe from the humidity of the atmoſphere, and which, in ſuch plants, are, of themſelves, ſufficient for effecting the purpoſes of vegetation. It is for this reaſon, that, unleſs in exceſſive hot weather, gardeners are ſeldom wont to water fat ſucculent plants, as the aloes, which rot, when they are moiſtened, if the ſun does not quickly dry them up.

The leaves of all the ever-green ſhrubs and trees, have a thin compact ſkin, or cover, over their ſurface; as is eaſily diſcovered by macerating them in water, in order to ſeparate the parenchyma, or pulp, from the veſſels of the leaves; which cannot be effected in any of theſe ever-greens, till a thin parchment-like cover is taken off. Theſe trees and ſhrubs are found by experiment to perſpire but little, when compared with others which ſhed their leaves; and it is, perhaps, principally owing to this cloſe covering, as alſo to the ſmall proportion of moiſture contained in their veſſels, that they retain their verdure, and continue through the winter on the trees. The nutritive juices of theſe plants always abound, more or leſs, with an oily quality, which ſecures them from being injured by ſevere froſts; ſo that many of theſe ever-green trees are adapted to grow in the coldeſt parts of the habitable world.

With reſpect to deciduous trees, the falling off of the leaves ſeems principally to depend on the temperature of the atmoſphere, which likewiſe ſerves to haſten or retard the appearance in queſtion. An ardent ſun contributes to haſten the dropping of the leaves. Hence in hot and dry ſummers, the leaves of the lime-tree and horſe-cheſnut turn yellow about the firſt of September; whilſt in other years, the yellowneſs does not appear till the beginning of October. Nothing, however, contributes more to haſten the fall of the leaves, than immoderate cold or moiſt weather in autumn; moderate droughts, on the other hand, ſerve to retard it. As a proof of this poſition, Mr. Adanſon relates, that in the year 1759, the leaves of the elm-tree, which generally fall off about the 25th of November, continued in verdure and vigour at Paris, where the autumn was remarkably dry, till the 10th of the following month.

It deſerves to be remarked, that an ever-green tree grafted upon a deciduous, determines the latter to retain its leaves. This obſervation is confirmed by repeated experiments; particularly by grafting the laurel, or cherry-bay, an ever-green, on the common cherry; and the ilex, or ever-green oak, on the oak.

DEFORCEMENT, in law, a with-holding lands, or tenements, by force, from the right owner. Deforcement, in the law of Scotland, is uſed for the reſiſting, or offering violence to the officers of the law, while they are actually employed in the exerciſe of their functions.

DEFORMITY is immediately oppoſed to beauty, and denotes the want of that uniformity, ſymmetry, and variety, neceſſary to conſtitute beauty. Accordingly, Dr. Hutcheſon defines it by the abſence of beauty, or a deficiency in the beauty expected in any ſpecies. Deformity and beauty may be conſidered either as natural or moral. Theſe are both referred by the above mentioned ingenious writer to an internal ſenſe; and our perceptions of them, as he ſuppoſes, ariſe from an original, arbitrary ſtructure of our own minds, by which certain objects, when obſerved, are rendered the occaſions of certain ſenſations and affections. There are many faces which, at firſt view, are apt to raiſe diſlike. But this is generally not from any poſitive deformity, but either from want of expected beauty, or from the carrying ſome natural indications of morally bad diſpoſitions, which we all acquire a faculty of diſcerning in countenances, airs, and geſtures.

The caſual conjunction of ideas gives us diſguſt, where there is nothing diſagreeable in the form itſelf. And this, in effect, is the cauſe of moſt of our fantaſtic averſions to the figures of divers animals. Thus ſerpents of all kinds, and many inſects really beautiful, are beheld with averſion by many people, who retain ſome accidental ideas of miſchief aſſociated to them. A ſimilar reaſoning is applied to our perception of moral beauty and deformity. But it is more juſt to diſtinguiſh between the ſentiments of delight or diſguſt, excited in us by beautiful or deformed objects, which are effects of ſome cauſes, and the natural and real qualities of the perceived objects by which they are produced. What is right in actions and characters is beautiful and amiable, and gives pleaſure; what is wrong is deformed and odious, and excites diſguſt: right and pleaſure, wrong and pain, are as diſtinct as cauſe and effect. Moral beauty and deformity are real qualities of certain actions; in which conſiſts their aptitude to pleaſe or diſguſt. With reſpect to natural beauty, uniformity amidſt variety pleaſes, becauſe of the natures of variety and uniformity, which are ſuch, that whenever united, they are adapted to pleaſe every free, unbiaſſed mind, that diſcerns them. Diſorder and confuſion, whence deformity ariſes, denote only the negation of regularity and order; or any arrangement and diſpoſition of things, which are not according to a law, rule, or plan, and prove not deſign. Theſe are not poſitively diſpleaſing; except where we previouſly expected order, or where impotence or want of ſkill appear, and the contriver has either failed of his deſign, or executed it ill. See on this ſubject Dr. Price's Review of the principal Queſtions and Difficulties in Morals, ch. ii. paſſim. See an admirable Eſſay on bodily Deformity, by Mr. Hay, in the Fugitive Pieces, vol. i. p. 93, &c.

DEGENERATION, or **DEGENERATING**, in general, denotes the growing worſe, or loſing ſome valuable qualities whereof a thing was formerly poſſeſſed. Some naturaliſts have been of opinion, that things are capable of degenerating into quite a diſtinct ſpecies; but this is a mere chimera. All that happens in the degeneration of a plant, for inſtance, is the loſing its uſual beauty, colour, ſmell, &c. a misfortune entirely owing to its being planted in an improper ſoil, climate, &c.

DEGLUTITION, in medicine, the act of ſwallowing the food. Deglutition is performed, in the firſt place, by means of the tongue, driving the aliment into the œſophagus, or gullet; and then, by the contraction of the ſphincter, and the fleſhy fibres of the ſame œſophagus, which, leſſening the bore, or aperture thereof protrude the contents downwards into the ſtomach, in our eating. Deglutition ſucceeds maſtication, and is followed by concoction. A difficulty of ſwallowing may be occaſioned by ulcers of the œſophagus, by a ſchirrous, bronchocelle, by a thickening of the mucus in the œſophagus, by induration of the œſophagus, by a fungus in it, by a ſacculus formed by ſome hard ſubſtance lodged in it, and weakening its coats, and by ſpaſms. Dr. Duncan, in his Medical Caſes, 1778, mentions the caſe of a difficult deglutition, ſuppoſed to ariſe from a venereal infection, in which electrical ſparks, applied to the fauces, were of conſiderable ſervice, and by degrees removed the complaint.

DEGRADATION, in our law-books called diſgradation, and depoſition, the act of depriving, or ſtripping a perſon for ever of a dignity, or degree of honour; and taking away the title, badge, and privileges thereof.

Sir Andrew Harela, Earl of Carliſle, being attainted and convicted of treaſon, 18 Edw. II. *coram rege*; after judgment was pronounced on him, his ſword was broken over his head, and his ſpurs hewn off his heels; Sir Antony Lucy, the judge, ſaying to him, "Andrew, now art thou no knight, but a knave." By ſtat. 13. Car. II. William lord Monſon, Sir Henry Mildmay, and others, were degraded from all titles of honour, dignities, and pre-eminences, and prohibited to bear, or uſe, the title of lord, knight, eſquire, or gentleman, or any coat of arms, for ever afterwards. It has been maintained that the king may degrade a peer; but it appears from later authorities, that he cannot be degraded but by act of parliament. When Cranmer, archbiſhop of Canterbury, was degraded, by order of queen Mary, they dreſſed him in epiſcopal robes made only of canvas, put the mitre on his head, and the paſtoral ſtaff in his hand; and in this attire ſhewed him to the people. Which done, they ſtripped him again, piece by piece. With us, a prieſt, after having been delivered to his ordinary, if he cannot purge himſelf of the crime laid at his door, has his gown, and other robes, ſtripped over his ears by the common hangman; by which he is declared diveſted of his orders.

DEGRADATION *of Tints*, in painting, expreſſes degrees of colour in the diſtant objects, in order to give them a natural effect.

DEGREE, quality, rank, condition, or dignity, ſtate or condition of a thing, which may be either heightened or lowered, increaſed or diminiſhed; meaſure; proportion; or quantity. In geometry, the 360th part of the circumference of a circle. In chymiſtry, a greater or leſs intenſeneſs of heat. In canon law, an interval in kinſhip, from whence nearneſs or remoteneſs of blood are computed. In muſic, the little intervals which compoſe the concords. The different orders or claſſes of the angelic bodies.

DEGREE *of Latitude* is, on the ſuppoſition of the ſphericity of the earth, the 360th part of the meridian; or more generally, it is that ſpace through which an obſerver muſt move on the meridian, in order to increaſe or diminiſh the diſtance of a ſtar from the zenith by one degree. See Syſtem of GEOGRAPHY.

DEGREE *of Longitude*, is the ſpace between two meridians; the quantity of which is variable according to the latitude. See Syſtem of GEOGRAPHY.

DEGREE, in univerſities, denotes a quality conferred on the ſtudents, or members of them, as a teſtimony of their proficiency in the arts or faculties; and entitling them to certain privileges, precedencies, &c. The degrees are much the ſame in the ſeveral univerſities: but the laws of them, and the diſcipline or exerciſe previous to their being obtained, differ. The degrees are, bachelor, maſter, and doctor; inſtead of the ſecond, in ſome foreign univerſities, they have licentiate. In each faculty there are but two degrees, viz. bachelor and doctor, which were antiently called bachelor and maſter: nor do the arts admit of more than two, which ſtill retain the denomination of the ancient degrees, viz. bachelor and maſter. At Oxford, degrees of maſter and doctor are only conferred once a year, viz. on Monday after the ſeventh of July, when a ſolemn act is held for the purpoſe.

The expences of a degree of doctor in any of the faculties, in treats and ſet fees, uſually amount to 100*l.* and that of a maſter of arts to 20 or 30*l.* The degree of bachelor is only conferred in Lent. To take the degree of bachelor of arts, four years are required, and three more for maſter of arts. At Cambridge, matters are nearly on the ſame footing, only the diſcipline is ſomewhat more ſevere, and the exerciſes more difficult. The commencement, which anſwers to the act of Oxford, is the Monday before the firſt Tueſday in July. The degrees of bachelor are taken up in Lent, beginning on Aſh Wedneſday.

The degree of maſter of arts is not given till above three years after that of a bachelor; during which time, the candidate is obliged, three ſeveral times, to maintain two philoſophical queſtions in the public ſchools, and to anſwer the objections raiſed againſt him by a maſter of arts. He muſt alſo keep two acts in the bachelor's ſchool, and declaim one. To paſs the degree of doctor in divinity at Oxford, it is neceſſary that the candidate has been four years bachelor of divinity. For doctor of laws, he muſt have been ſeven years in the univerſity to commence bachelor of law; five years after which he may be admitted doctor of laws. Otherwiſe, in three years after taking the degree of maſter of arts, he may take the degree of bachelor in law; and in four years more, that of LL. D. which ſame method and time are likewiſe required to paſs the degree of doctor in phyſic.

At Cambridge, to take the degree of doctor in divinity, it is required that the candidate has been ſeven years bachelor of divinity. Though in ſeveral of the colleges, the taking of the bachelor of divinity's degree is diſpenſed with, and they may go out *per ſaltum*. To commence doctor in laws, the candidate muſt have been five years bachelor of law, or ſeven years maſter of arts. To paſs doctor in phyſic, he muſt have been bachelor in phyſic five years, or ſeven years maſter of arts. A doctor of the civil law, may exerciſe eccleſiaſtical juriſdiction, though a layman, ſtat. 37 Hen. VIII. cap. 17. ſect. 4.

DEJECTION, in medicine, the act of avoiding the excrements

ments by the anus. When the fæces are accumulated in the inteſtinum rectum in ſufficient quantity to become troubleſome either by their weight or acrimony, they excite a certain uneaſineſs, which produces an inclination to go to ſtool. The efforts for this purpoſe are begun by a conſiderable inſpiration, in conſequence of which the diaphragm is carried down towards the lower belly; the abdominal muſcles are at the ſame time contracted in obedience to the will; and the inteſtines being compreſſed on all ſides, the reſiſtance of the ſphincters is overcome, and the fæces paſs out at the anus: which is afterwards drawn up by its longitudinal fibres, which are called *levatores ani*, and then by means of its ſphincter is again contracted: but it ſometimes happens, as in dyſenteries, for inſtance, that the fæces are very thin, and have conſiderable acrimony; and then the irritation they occaſion is more frequent, ſo as to promote their diſcharge without any preſſure from the diaphragm or abdominal muſcles; and ſometimes involuntarily, as is the caſe when the ſphincters become paralytic.

DEIFICATION, in antiquity. See Apotheosis.

Deification, in the pagan theology, the act, or ceremony, of deifying their emperors, i. e. of placing them among the gods, and decreeing divine honours to be rendered them. See God, and Consecration.

DEISM, the doctrine, or belief of the deiſts. Deiſm, from Θεος, *God*, may properly be uſed to denote natural religion, as comprehending thoſe truths which have a real foundation in reaſon and nature; and in this ſenſe it is ſo far from being oppoſite to chriſtianity, that it is one great deſign of the goſpel to illuſtrate and enforce it. Thus ſome of the deiſtical writers have affected to uſe it; but deiſm more preciſely ſignifies that ſyſtem of religion, relating both to doctrine and practice, which every man is to diſcover for himſelf by the mere force of natural reaſon, independent of all revelation, and excluſive of it; and this religion Dr. Tindal, and others, pretend is ſo perfect, as to be incapable of receiving any addition or improvement, even from divine revelation.

DEISTS, a claſs of people known alſo under the denomination of free-thinkers, whoſe diſtinguiſhing character it is, not to profeſs any particular form, or ſyſtem, of religion; but only to acknowledge the exiſtence of a God, and to follow the light and law of nature, rejecting revelation, and oppoſing chriſtianity. This name ſeems to have been firſt aſſumed, as the denomination of a party, about the middle of the ſixteenth century, by ſome gentlemen in France and Italy, who were deſirous of thus diſguiſing their oppoſition to chriſtianity by a more honourable appellation than that of atheiſts. Viret, an eminent reformer, mentions certain perſons in his epiſtle dedicatory, prefixed to the ſecond tom. of his Inſtruction Chretienne, publiſhed in 1563, who called themſelves by a new name, that of deiſts. Theſe, he tells us, profeſſed to believe in God, but ſhewed no regard to Jeſus Chriſt, and conſidered the doctrine of the apoſtles and evangeliſts as fables, and dreams. He adds, that they laughed at all religion, though they outwardly conformed to the religion of thoſe with whom they lived, or whom they wiſhed to pleaſe, or feared to offend. Some, he obſerves, profeſſed to believe the immortality of the ſoul; others denied both this doctrine, and that of providence. Many of them were conſidered as perſons of acute and ſubtile genius, and took pains in diſſeminating their notions. See Bayle's Dict. art. Viret. vol. v. or Leland's View of the Deiſtical Writers, vol. i. p. 2.

The deiſts hold, that, conſidering the multiplicity of religions, the numerous pretences to revelation, and the precarious arguments generally advanced in proof thereof, the beſt and ſureſt way is, to return to the ſimplicity of nature, and the belief of one God; which is the only truth agreed to by all nations. They complain that the freedom of thinking and reaſoning is oppreſſed under the yoke of religion; and that the minds of men are ridden, and tyrannized, by the neceſſity impoſed on them of believing inconceivable myſteries; and contend, that nothing ſhould be required to be aſſented to, or believed, but what their reaſon clearly conceives.

The diſtinguiſhing character of modern deiſts is, that they reject all revealed religion, and diſcard all pretences to it, as the effects of impoſture and enthuſiaſm. They profeſs a regard for natural religion, though they are far from being agreed in their notions concerning it. They are claſſed by ſome of their own writers into mortal and immortal deiſts: the latter acknowledging a future ſtate, and the former denying it, or repreſenting it as very uncertain. Oracles of reaſon, p. 99.

Dr. Clarke diſtinguiſhes four ſorts of deiſts. 1. Thoſe who pretend to believe the exiſtence of an eternal, infinite, independent, intelligent being, who made the world, without concerning himſelf in the government of it. 2. Thoſe who believe the being and natural providence of God, but deny the difference of actions, as morally good or evil, reſolving it into the arbitrary conſtitution of human laws; and therefore they ſuppoſe that God takes no notice of them. With reſpect to both theſe claſſes, he obſerves, that their opinion can conſiſtently terminate in nothing but downright atheiſm. 3. Thoſe who having right apprehenſions concerning the nature, attributes, and all governing providence of God, ſeem alſo to have ſome notion of his moral perfections, though they conſider them as tranſcendant, and ſuch in nature and degree, that we can form no true judgment, nor argue with any certainty concerning them: but they deny the immortality of human ſouls, alledging, that men periſh at death, and that the preſent life is the whole of human exiſtence. 4. Thoſe who believe the exiſtence, prefections, and providence of God, the obligation of natural religion, and a ſtate of future retribution, on the evidence of the light of nature, without a divine revelation: ſuch as theſe, he ſays, are the only true deiſts, but their principle, he apprehends, ſhould lead them to embrace chriſtianity; and therefore he concludes, that there is now no conſiſtent ſcheme of deiſm in the world. Evidence of Nat. and Rev. Religion, p. 12. 27.

The firſt deiſtical writer of any note that appeared in this country, was Herbert baron of Cherbury. He lived and wrote in the laſt century. His book De Veritate was firſt publiſhed at Paris in 1624. This, together with his book De Cauſis Errorum, and his Treatiſe De Religione Laici, were afterwards publiſhed in London. His celebrated work De Religione Gentilium, was publiſhed at Amſterdam in 1663, in 4to. and in 1700 in 8vo. and an Engliſh tranſlation of it was publiſhed at London in 1705. As he was one of the firſt that formed Deiſm into a ſyſtem, and aſſerted the ſufficiency, univerſality, and abſolute perfection of natural religion, with a view to diſcard all extraordinary revelation, as uſeleſs and needleſs, we ſhall ſubjoin the five fundamental articles of this univerſal religion. They are theſe: 1. That there is one ſupreme God. 2. That he is chiefly to be worſhipped. 3. That piety and virtue are the principal part of his worſhip. 4. That we muſt repent of our ſins; and if we do ſo, God will pardon them. 5. That there are rewards for good men, and puniſhments for bad men, both here and hereafter. Our own age has produced a number of advocates in the ſame cauſe; and however they may have differed among themſelves, they have been agreed in their attempts of invalidating the evidence and authority of divine revelation. We might mention Hobbes, Blount, Toland, Collins, Woolſton, Tindal, Morgan, Chubb, lord Bolingbroke, Hume, &c. Some have alſo added lord Shafteſbury to the number.

But the friends of Chriſtianity have no reaſon to regret the free and unreſerved diſcuſſion which their religion has undergone. Objections have been ſtated and urged in their full force, and as fully anſwered; argument and raillery have been repelled; and the controverſy between Chriſtians and Deiſts has called forth a great number of excellent writers, who have illuſtrated both the doctrines and evidence of Chriſtianity in a manner that will ever reflect honour on their names, and be of laſting ſervice to the cauſe of genuine religion, and the beſt intereſts of mankind.

The number of Deiſts is ſaid to be daily increaſing: in England, many men of ſpeculation and letters are ſaid to incline that way; and the like is obſerved in ſome of our neighbouring nations, where freedom of ſpeaking, writing, and thinking, are indulged. Not that unreſtrained liberty in this reſpect can ever injure Chriſtianity, or ſerve the cauſe of Deiſm: truth neither needs nor ſeeks diſguiſe; but where freedom is allowed, men's ſentiments, on the ſubject of religion, are more generally known.

DEITY, *Godhead*; a common appellation given to God; and alſo by the poets to the heathen gods and goddeſſes.

DELEGATES, certain perſons delegated, or appointed by the king's commiſſion, under the great ſeal, to ſit upon an appeal to the king in the court of chancery.

DELEGATION, a commiſſion extraordinary given a judge, to take cognizance of and determine ſome cauſe, which ordinarily does not come before him. In the civil law, delegation alſo denotes a ſort of ſurrender, whereby a perſon ſubſtitutes another debtor in his place.

DELETERIOUS (from δηλεω, *neco*, *I hurt*) a term ſometimes uſed among naturaliſts, for ſuch things as are of a pernicious and poiſonous nature.

DELF *of Coal*, denotes coal lying in veins under ground, before it is dug up.

Delf is alſo uſed in heraldry, for one of the abatements of honour; being a ſquare in the middle of the eſcutcheon.

Delf *Ware*, a kind of pottery of baked earth, covered with an enamel, or white glazing, which gives it the appearance and neatneſs of porcelain. The baſis of this pottery is clay; and the kinds of clay chiefly uſed are the blue and green, with an addition of marle or ſand, in order to leſſen the contraction of the clay, to render it leſs compact, and to afford a better ground for the enamel. Red clay is alſo added, which, on account of its ferruginous matter, binds and gives a greater ſolidity. The proportions of theſe ingredients vary in different works, according to the different qualities of the earths employed. Three parts of blue clay, two of red clay, and five parts of marle, form the compoſition uſed in ſeveral manufactories. Veſſels formed of theſe materials muſt be dried very gently, to avoid cracking. They are then to be placed in a furnace to receive a ſlight baking, and they are laſtly to be covered with an enamel or glazing, which is done by pouring upon the veſſels thus prepared, the enamel, which has been ground very fine, and diluted with water. The glazing, which is nothing but white enamel, ought to be ſo opake as not to ſhew the ware under it. The enamels for delf-ware are compoſed of ſand or flints, vitrifying ſalts, calx of lead, and calx of tin. The vitrification of ſand is effected by ſomewhat leſs than an equal part of alkaline ſalt, or twice its weight of calx of lead, and one part of calx of tin, which is deſigned for giving a white opake colour to the maſs, is to be added to three or four parts of all the other ingredients taken together. M. D'Antic recommends for the white enamel, uſed in glazing, a mixture of an hundred pounds of calx of lead, with about a ſeventh part of that quantity of calx of tin for common delf, or a fourth part of calx of tin for the fineſt delf; a hundred, or a hundred and ten pounds of fine ſand; and about twenty or thirty pounds of ſea-ſalt, or ſalt of glaſs. To make this enamel, lead and tin are calcined together with a ſtrong fire, or the ſand is alſo to be made into a fritt, with the ſalt or aſhes. The whole being well mixed and ground together, is placed under the furnace, where it is melted and vitrified during the baking of the ware. Then it is to be ground in a mill, and applied as above directed. Dict. of Chem. Eng. edit. 1777. See ENAMEL, GLAZING, and PORCELAIN.

DELIA, Δηλια, in antiquity, a quinquennial feſtival in the iſland of Delos, inſtituted by Theſeus in honour of Venus. Pott. Archæol. Græc. lib. ii. cap. 20.

DELIBERATIVE, is applied to that kind, or branch, of rhetoric employed in proving a thing, or convincing an aſſembly thereof, in order to perſuade them to put it in execution.

DELICACY, daintineſs, or taſte ſhewn in eating; any thing which affects the ſenſes with great pleaſure; elegant ſoftneſs of form; nicety, or minute accuracy. Genteel neatneſs, applied to dreſs. Politeneſs of behaviour; indulgence which produces weakneſs; tenderneſs; weakneſs of conſtitution; a diſpoſition which is ſhocked with any ſucceſs.

DELICT, in Scots law, ſignifies ſuch ſmall offences or breaches of the peace as are puniſhable only by fine or ſhort impriſonment.

DELIGATION, *Deligatio*, that part of ſurgery which relates to the binding up of wounds, ulcers, broken bones, &c. See Syſtem of SURGERY.

DELINQUENT, a guilty perſon, or one who has committed ſome fault or offence for which he is puniſhable.

DELIQUESCENCE, in chymiſtry, denotes the property which certain bodies poſſeſs of attracting moiſture from the air, and of thereby becoming liquid. It is peculiar to ſaline ſubſtances, or bodies containing them, and reſults from their affinity with water.

DELIQUIUM, or DELIQUIUM *Animi*, from *delinquo*, *I ſwoon*, a ſwooning, or fainting away; called alſo ſyncope, lypothymia, lypopſychia, eclyſis, and aſphyxia.

DELIQUIUM from *deliqueſco*, *to be diſſolved*, in chymiſtry, is the diſſolution, or melting, of ſalt, or calx, by ſuſpending it in a moiſt cellar. Salt of tartar or any fixed alkali, ſet in a cellar, or other cool moiſt place, and in an open veſſel, reſolves, or runs, into a kind of liquor, called by the chymiſts oil of tartar, *per deliquium*.

DELIRIUM, from *deliro*, to rave or talk idly. When the ideas excited in the mind do not correſpond to the external objects, but are produced by the change induced on the organs of ſenſation, the patient is ſaid to be delirious. The Greeks call it *paraphreneſis*. In the Engliſh there is no word for it, except lightheadedneſs be admitted.

The paraphreneſis, or delirium, differs from a madneſs, in not being perpetual, which happens in delirium without a fever. The proximate cauſe of a delirium is an affection of the brain; but the remote cauſes may be an irritation, ſometimes a very ſlight one, of any part of the nervous ſyſtem.

DELIVERY, *Parturition*, or child-birth, the bringing forth of a perfect fœtus, or child, out of its mother's womb; whether it be living or dead. See Syſtem of MIDWIFRY.

DELPHINIUM, DOLPHIN-FLOWER, or LARK-SPUR; a genus of the triginia order, belonging to the polyandria claſs of plants. There are ſeven ſpecies; four are cultivated in gardens Two of theſe are annual, and two perennial. See Syſtem of BOTANY. Sect. V. and Plate V.

DELPHINUS, the dolphin, in aſtronomy, a conſtellation of the northern hemiſphere. See Syſtem of ASTRONOMY, Sect. VIII.

DELPHINUS, a genus of fiſhes belonging to the order of Cete. There are three ſpecies; 1. The delphis, or dolphin; 2. The phocæna, or porpeſſe, found in vaſt multitudes in the Britiſh ſeas. 3. The orca, or grampus, remarkably thick in proportion to its length, one of 18 feet being in the thickeſt part 10 feet diameter. Theſe fiſhes, and all of the order of Cete are obſerved to ſwim againſt the wind, and to be much diſturbed, and tumble about with unuſual violence, at the approach of a ſtorm.

DELPHOS, in antiquity, now called Caſtri, the capital of Phocis in Achaia, anciently much celebrated for its temple, and oracle of Apollo. This temple was a magnificent ſtructure, enriched with innumerable gifts, in it was the dark cave Pithium, where the prieſteſs, named Pythia, ſitting on a tripos, or three legged ſtool, pretended to receive the inſpiration of the god. The town of Caſtri ſtands between Salena and Livadia, about ten miles diſtant from the ſide of mount Parnaſſus, ſo famous in antiquity, and ſacred to the Muſes and Apollo.

DELTOIDES, in anatomy, a triangular muſcle of the ſhoulder; thus called from the Greek *delta*, Δ, and ειδος, *form*. See Syſtem of ANATOMY. Part III. Sect. XIV.

DISSERTATION ON THE DELUGE.

DELUGE, DILUVIUM, a flood, or inundation of water, covering the earth, either in the whole or part.

We meet with divers accounts of deluges in hiſtory, that which happened in Greece, in the time of Deucalion, called *Diluvium Deucalioneum*: this deluge only overflowed Theſſaly. Its date is fixed to the year before Chriſt 1529, being the third year before the Iſraelites coming out of Egypt, according to the computation of Petavius. Rat. Temp. par. i. lib. i. cap. 7.

The deluge of Ogyges happened near three hundred years before that of Deucalion, 1020 years before the firſt Olympiad, and 1796 before Jeſus Chriſt, according to the ſame author, Rat. Tem. pa. i. cap. 4 par. ii. lib. ii. cap. 5. This only ravaged Attica. Theſe two deluges are frequently mentioned, in ancient Greek authors, under the denomination of *cataclyſmus prior*, and *poſterior*. Of the like kind were thoſe inundations in the Netherlands, which, in 1727, overwhelmed and covered with ſea all that part now called Gulf Dollart in the United Netherlands; and in 1421, all that part between Brabant and Holland. But the moſt memorable deluge is that which we particularly, by way of eminence, call the deluge, or the univerſal deluge, or Noah's flood: recorded in Scripture as a general inundation ſent by God to puniſh the corruption of the world, at that time, by deſtroying every thing from the face of the earth, except Noah and his family, and what was ſhut up with him in the ark. This flood makes one of the moſt conſiderable epochas in chronology. Its hiſtory is given by Moſes, Gen. ch. vi. and vii. Its time is fixed by the beſt chronologer, to the year from the creation 1656, anſwering to the year before Chriſt 2293. From this flood the ſtate of the world is divided into diluvian, and antediluvian. The deluge has been, and remains yet a ſubject of much inquiry and diſpute among naturaliſts, critics, &c. The points chiefly controverted may be reduced to three: firſt, its extent, viz. whether it were general, or partial; ſecondly, its natural cauſe; and thirdly, its effects.

1. The immenſe quantity of water, requiſite to furniſh an univerſal deluge, has occaſioned ſeveral authors to ſuſpect it only partial. An univerſal deluge, they think, had been unneceſſary, conſidering the end for which it was brought, viz. to extirpate the wicked inhabitants. The world was then but new, and the people not many; the holy Scriptures making only eight generations from Adam to Noah. It was but a ſmall part of the earth that could be yet inhabited; the country about the Euphrates, which is ſuppoſed to have been the ſcene of the firſt antediluvian inhabitants, was ſufficient to bear them all. Now Providence, they argue, which ever acts wiſely, and frugally, would never have diſproportioned the means to the end, ſo far as to overflow the whole globe, only to drown a little corner of it. They add, that, in the Scripture language, the whole earth expreſſes no more than all the inhabitants; and on this principle advance, that an overflowing of the Euphrates and Tigris, with a vehement rain, &c. might anſwer all the phenomena of the deluge.

But the deluge was univerſal. God declared to Noah, Gen. vi. 17. that he was reſolved to deſtroy every thing that had breath under heaven, or had life on the earth, by a flood of waters; ſuch was the menace; ſuch the execution. The waters, Moſes aſſures us, covered the whole earth, buried all the mountains, and were no leſs than fifteen cubits above the higheſt of them: every thing periſhed therein; birds, beaſts, men, and all that had life, excepting Noah, and thoſe with him in the ark, Gen. vii. 19, &c. Can an univerſal deluge be more clearly expreſſed? If the deluge had only been partial, there had been no neceſſity to ſpend an hundred years in the building of an ark, and ſhutting up all the ſorts of animals therein, in order to re-ſtock the world: they had been eaſily and readily brought from thoſe parts of the world not overflowed, into thoſe that were; at leaſt, all the birds would never have been deſtroyed, as Moſes ſays they were, ſo long as they had wings to bear them to thoſe parts where the flood did not reach. If the waters had only overflowed the neighbourhood of the Euphrates and Tigris, they could not be fifteen cubits above the higheſt mountains; they could not have riſen to that height, but they muſt ſpread themſelves, by the laws of gravity, over the reſt of the earth: unleſs, perhaps, they had been retained there by a miracle; and, in that caſe, Moſes, no doubt, would have related the miracle, as he did that of the waters of the Red ſea, and the river Jordan, which were ſuſtained in a heap, to give paſſage to the Iſraelites, Exod. xiv. 22. and Joſh. iii. 16. Add, that, in regions far remote from the Euphrates and Tigris, viz. in Italy, France, Switzerland, Germany, England, &c. there are frequently found, in places many ſcores of leagues from any ſea, and even in the tops of high mountains, whole trees ſunk deep under-ground; as alſo teeth and bones of animals, fiſhes entire, ſea-ſhells, ears of corn, &c. petrified; which the beſt naturaliſts are agreed could never have come there but by the deluge; to which may be added the almoſt univerſal traditions of this great event in all countries of the globe.

2. The deluge allowed univerſal, the philoſophers are ſolicitous

to find water to effect it. Moſes brings it from two ſources: *the fountains of the great deep were broken up*; *and the windows of heaven were opened.* Dr. Burnet, in his Telluris Theoria ſacra, ſhews, that all the waters of the ocean were not near enough to cover the earth fifteen cubits above the tops of the higheſt mountains. According to his computation, no leſs than eight oceans were required. Suppoſing the ſea, therefore, drained quite dry, and all the clouds of the atmoſphere diſſolved into rain, we ſhould ſtill want much the greateſt part of the water of a deluge.

To get clear of this embarraſſment, many of our beſt naturaliſts, at Steno, Burnet, Woodward, Scheuchzer, &c. adopt Des Cartes' Syſtem of the formation of the Earth. That philoſopher will have the primitive world to have been perfectly round and equal, without mountains, or vales; and accounts for its formation on mechanical principles, by ſuppoſing it at firſt in the condition of a thick turbid fluid, replete with diverſe heterogeneous matters, which, ſubſiding by ſlow degrees, formed themſelves into different concentric ſtrata, or beds, by the laws of gravity; and thus, at length, left a dry, ſolid earth. Dr. Burnet improves on this theory: he ſuppoſes the primitive earth to have been no more than an orbicular cruſt, inveſting the face of the abyſs, or deep, which grew chinky, clave, burſt, and fell down into the water, and ſo drowned its inhabitants.

The ſame theoriſt adds, that by this cataſtrophe, the globe of the earth was not only ſhaken, and broken in a thouſand places, but the violence of the ſhock it then underwent ſhifted its ſituation; ſo that the earth, which before was placed directly under the zodiac, became thenceforth oblique to the ſame. Whence aroſe the difference of ſeaſons, which the antediluvian earth was not expoſed to.

Dr. Burnet's hypotheſis is very elegantly recited; but it not only contradicts the phyſical principles of nature, but is alſo utterly inconſiſtent with the ſacred text above-cited, which expreſly mentions mountains as the ſtandard of the height of the water; or with that other paſſage, Gen. viii. 22. where God, promiſing not to bring any more deluges, but that every thing ſhould be reſtored to its ancient ſtate, ſays, that *ſeed-time and harveſt, and cold and heat, and ſummer and winter, and day and night, ſhall ceaſe no more.* See Keil's Exam. of the Theory of the Earth.

Other authors, ſuppoſing a ſufficient fund of water in the abyſs, or ſea, are only concerned for an expedient to bring it forth: accordingly, ſome, as Mr. Ray, &c. have recourſe to a ſhifting of the earth's centre, which, drawing after it the water out of its channel, overwhelmed the ſeveral parts of the earth ſucceſſively. But this could only occaſion a partial deluge in that part of the globe towards which the centre of gravity was tranſlated: nor can the poſſibility of ſuch a tranſlation be allowed, ſince the centre of gravity is the neceſſary reſult of the materials compoſing our globe, and not alterable whilſt the parts remained in the ſame poſition.

Dr. Hook's opinion of the compreſſion of a ſhell of earth into a prolate ſpheroid, thereby preſſing out the water of an abyſs under the earth, may very well account for the waters overſlowing two oppoſite zones of the globe; but the middle zone being by much the greater part of the earth's ſurface, muſt by this means be raiſed higher from the centre, and conſequently ariſe more out of the water than before.

3. But the great difficulty ſtill remains. The orderly ſtrata, or layers of the earth, with the exuviæ, or remains of fiſhes, as their teeth, bones, ſhells, &c. both marine, and fluviatile, found in the bodies even of the moſt ſolid ſtrata, and in flints, marbles, &c. are not yet accounted for. Thoſe who adhere to Des Cartes' ſyſtem, as Steno, &c. take the finding of the part of terreſtrial, and aquatic animals, branches of trees, leaves, &c. in the beds, or ſtrata of ſtone, to be a direct proof of the primitive fluidity of the earth. But then they are obliged to have recourſe to a ſecond formation of ſtrata, much later than the firſt; becauſe at the time of the firſt there was neither plant nor animal, in being. Steno, therefore, maintains ſecond formations, occaſioned at different times by extraordinary inundations, earthquakes, volcanos, &c. But Burnet, Woodward, Scheuchzer, &c. chooſe rather to attribute a ſecond general formation to the deluge; without excluding, however, particular ones of Steno. But the great objection againſt this ſyſtem of fluidity, is mountains; for the whole globe being liquid, whence ſhould ſuch inequalities ariſe? Mr. Scheuchzer, rather than part with a ſyſtem which ſeems ſo promiſing, give into the opinion of thoſe who hold, that, after the deluge, God, to remit the waters into their ſubterranean reſervoirs, broke and diſplaced, with his own almighty hand, a great number of ſtrata, that were before horizontal, and raiſed them above the ſurface of the earth; whence it is, that the ſtrata in mountains, though concentrical, are never horizontal. Hiſt. de l'Acad. 1708, p. 32.

According to Mr. de la Pryme, the antediluvian world had an external ſea, as well as land, with mountains, rivers, &c. and the deluge was effected by breaking the ſubterraneous caverns, and pillars thereof, with dreadful earthquakes, and cauſing the ſame to be for the moſt part, if not wholly abſorbed and ſwallowed up, and covered by the ſeas that we now have. Laſtly, this earth of ours aroſe out of the bottom of the antediluvian ſea; and in its room, juſt as many iſlands are ſwallowed down, and others thruſt up in their ſtead. On this, as on all the other hypotheſes, it may be remarked, that it is quite arbitrary, and without the leaſt foundation from the words of Moſes. The ſacred hiſtorian ſpeaks not one word, of earthquakes; nay, from the nature of the thing, we know it is impoſſible that the flood could have been occaſioned by an earthquake, and the ark preſerved, without a miracle. It is certain, that if a ſhip ſinks at ſea, the commotion excited in the water by the deſcent of ſuch a large body, will ſwallow up a ſmall boat that happens to come too near. If the pillars of the earth itſelf then were broken, what muſt the commotion have been, when the continents of Europe, Aſia, and Africa, deſcended into the abyſs at once? Not to mention America, which lying at ſo great a diſtance from Noah, he might be ſuppoſed out of danger from that quarter. By what miracle was the little ark preſerved amidſt the tumult of thoſe impetuous waves which muſt have ruſhed in from all quarters? Beſides, as the ark was built not at ſea, but on dry ground; when the earth on which it reſted ſunk down, the ark muſt have ſunk along with it; and the waters falling in as it were over-head, muſt have daſhed in pieces the ſtrongeſt veſſel that can be imagined. Earthquakes, alſo, operate ſuddenly and violently; whereas, according to the Moſaic account, the flood came on gradually, and did not arrive at its height till ſix weeks, or perhaps five months, after it began.

Having ſtated ſome of the principal arguments advanced by philoſophers, critics, &c. we ſubmit them to the judgment of the reader; and take the liberty of ſubjoining ſome remarks of our own on the ſubject.

We muſt obſerve, that there is a very general miſtake with regard to the air; it being imagined, becauſe the air does not always deluge with exceſſive rains, that it contains but little water. After the atmoſphere has been diſcharging for a number of days ſucceſſively, a quantity of matter 800 times heavier than itſelf, inſtead of being lightened by the diſcharge, it becomes heavier, nay ſpecifically heavier, than it was before. It is alſo certain that very dry air, provided it is not at the ſame time very hot, is always heavieſt; and the drieſt air which we are acquainted with, namely, Dr. Prieſtley's dephlogiſticated air, is conſiderably heavier than the air we commonly breathe. For theſe reaſons we think the quantity of water contained in the whole atmoſphere ought to be conſidered as indefinite, eſpecially as we know that by whatever agent it is ſuſpended, that agent muſt counteract the force of gravity, otherwiſe the water would immediately deſcend; and while the force of gravity in any ſubſtance is counteracted, that ſubſtance cannot appear to us to gravitate at all.

The above conſiderations render it probable at leaſt, that there is in nature a quantity of water ſufficient to deluge the world, provided it was applied to the purpoſe. We muſt next conſider whether there is any natural agent powerful enough to effectuate this purpoſe. We ſhall take the phraſes uſed by Moſes in their moſt obvious ſenſe. The breaking up of the fountains of the deep we may reaſonably ſuppoſe to have been the opening of all the paſſages whether ſmall or great, through which the ſubterraneous waters poſſibly could diſcharge themſelves on the ſurface of the earth. The opening of the windows of heaven we may alſo ſuppoſe to be the pouring out of the waters, contained in the atmoſphere, through thoſe inviſible paſſages by which it enters in ſuch a manner as totally to elude every one of our ſenſes, as when water is abſorbed by the air in evaporation. As both theſe are ſaid to have been opened at the ſame time, it ſeems from thence probable, that one natural agent was employed to do both.

Now it is certain, that the induſtry of modern inquiries hath diſcovered an agent unknown to the former ages, and whoſe influence is ſo great, that with regard to this world it may be ſaid to have a kind of omnipotence. The agent we mean is electricity. It is certain that, by means of it, immenſe quantities of water can be raiſed to a great height in the air. This is proved by the phenomena of water-ſpouts. Mr. Forſter relates, that he happened to ſee one break very near him, and obſerved a flaſh of lightning proceed from it at the moment of its breaking. The concluſion from this is obvious. When the electric matter was diſcharged from the water, it could no longer be ſupported by the atmoſphere, but immediately fell down. Though water-ſpouts do not appear in this country, yet every one muſt have made an obſervation ſomewhat ſimilar to Mr. Forſter's. In a violent ſtorm of thunder and rain, after every flaſh of lightning, or diſcharge of electricity from the clouds, the rain pours down with increaſed violence; thus ſhewing, that the cloud, having parted with ſo much electricity, cannot longer be ſupported in the form of vapour, but muſt deſcend in rain. It is not indeed yet diſcovered that electricity is the cauſe of the ſuſpenſion of water in the atmoſphere; but it is certain that evaporation is promoted by electrifying the fluid to be evaporated. It may therefore be admitted as a poſſibility, that the electric fluid contained in the air is the agent by which it is enabled to ſuſpend the water which riſes in vapour. If therefore the air be deprived of the due proportion of this fluid, it is evident that rain muſt fall in prodigious quantities.

Again, we are aſſured from the moſt undeniable obſervations, that electricity is able to ſwell up water on the ſurface of the earth. This we can make it do even in our trifling experiments; and much more muſt the whole force of the fluid be ſuppoſed capable of doing it, if applied to the waters of the ocean, or any others, The agitation of the ſea in earthquakes is a ſufficient proof of this. It is certain, that at theſe times there is a diſcharge of a vaſt quantity of electric matter from the earth into the air; and as ſoon as this happens, all becomes quiet on the ſurface of the earth.

From a multitude of obſervations, it alſo appears, that there is, at all times, a paſſage of electric matter from the atmoſphere into the earth, and *vice verſa* from the earth into the atmoſphere. There is therefore no abſurdity in ſuppoſing the Deity to have influenced the action of the natural powers in ſuch a manner that for 40 days and nights the electric matter contained in the atmoſphere ſhould deſcend into the bowels of the earth; if indeed there is occaſion for ſuppoſing any ſuch immediate influence at all, ſince it is not impoſſible that there might have been, from ſome natural cauſe, a deſcent of this matter from the atmoſphere for that time. But by whatever cauſe the deſcent was occaſioned, the conſequence would be, the *breaking up of the fountains of the deep*, and the *opening the windows of heaven*. The water contained in the atmoſphere being left without ſupport, would deſcend in impetuous rains; while the waters of the ocean, thoſe from which fountains originate, and thoſe contained in the ſolid earth itſelf, would riſe from the very centre, and meet the waters which deſcended from above. Thus the breaking up of the fountains of the deep, and the opening the windows of heaven, would accompany each other, as Moſes tells us they actually did; for, according to him, both happened on the ſame day. In this manner the flood would come on quietly and gradually, without that violence to the globe which Burnet, Whiſton, and other theoriſts, are obliged to ſuppoſe. The abatement of the waters would enſue, on the aſcent of the electric fluid to where it was before. The atmoſphere would then abſorb the water as formerly; that which had aſcended through the earth would again ſubſide; and thus every thing would return to its priſtine ſtate. For a particular conſideration of theſe matters, ſee the articles EARTH, MOUNTAIN, and VOLCANO.

DEMAIN, or DEMESNE, in its popular ſenſe, denotes the lord's manor-place, with the lands thereto belonging; which he and his anceſtors have from time to time kept in their own manual occupation.

DEMAIN is ſometimes alſo taken, more largely, for lands and tenements held for life, &c. and ſometimes more ſtrictly for ſuch only as are generally held in fee.

DEMAND, in its proper ſenſe, denotes a calling for, or requiring one's due.

DEMAND, in law, has a more ſpecial ſignification, as contradiſtinguiſhed from plaint: for all civil actions are purſued, either by demands or plaints; according to which the purſuer is called either demandant, or plaintiff, viz. in real actions, demandant; and in perſonal actions, plaintiff. Where the party purſuing is demandant, the party purſued is called tenant; and where the former is called plaintiff, the latter is termed defendant. There are two kinds of demands: the one in deed, *de facto*, as in every precipe; the other in law, *de jure*; ſuch is entry in land, diſtreſs for rent, &c.

DEMEMBRE', in heraldry, is when an animal is diſmembered, i. e. the limbs cut off its body.

DEMI, a word of the ſame uſe and effect in the French language with *ſemi*, in the Latin and Engliſh; being formed from *dimidium*; and uſed, in compoſition with other words, to ſignify half. In words borrowed from the Latins, we uſe *ſemi*; and in thoſe from the French, we retain their *demi*.

DEMI *Baſtion*, a kind of fortification, that has only one face, and one flank.

DEMI *Cannon*, a piece of ordnance, uſually about ſix inches bore, 5400 pounds weight, ten or eleven feet long, and carrying a ſhot of 30 pound weight.

DEMI *Croſs*, an inſtrument uſed by the Dutch to take the ſun's altitude, or that of a ſtar, at ſea; but inſtead of which we uſe the croſs ſtaff or fore ſtaff.

DEMI *Culverin*, is a piece of ordnance commonly 4¼ inches bore, ten feet long, 2700 pounds weight; its charge is 7 pounds 4 ounces of powder; and it carries a ſhot of 10 pounds 11 ounces, and ſhoots point blank 175 paces.

DEMI *Gorge*, in fortification, is that part of the polygon which remains after the flank is raiſed, and goes from the curtin to the angle of the polygon. It is half of the vacant ſpace or entrance into a baſtion.

DEMI *Quaver*, is a note in muſic, two of which are equal to the quaver.

DEMISE, in law, is applied to an eſtate either in fee-ſimple, or fee-tail, or for term of life, or years; and ſo it is commonly taken in many writs. The king's death is, in law, termed, the demiſe of the king.

DEMISE *of the King* does not diſcontinue any writ or proceſs. Vide Stat. 1. Ed. VI. cap. 7. ſect. 1, 2, 3. Nor does it determine any commiſſion civil or military, or great office of ſtate, but they ſhall continue in force for ſix months after the ſovereign's demiſe, unleſs made void by the next ſucceſſor. Stat. 7 & 8 Will. III. cap. 27. ſect. 21. 1 Ann. ſtat. 1. cap. 8. 6 Ann. cap. 7. ſect. 8. Neither is a parliament thereby determined till after ſix months. 7 & 8 Will. III. cap. 15. Nor is a defendant, who hath pleaded to an information, obliged to plead to it again upon requeſt made to the court, within five months after the demiſe. 4 & 5 Will. & Mar. cap. 18. ſect. 7.

DEMISE, and REDEMISE, denote a conveyance where there are mutual leaſes made from one to another of the ſame land, or ſomething out of it.

DEMOCRACY, a form of government, wherein the ſovereignty, or ſupreme authority, is lodged in the people, who exerciſe the ſame by perſons of their own order, deputed for that purpoſe. The word is formed of the Greek δημος, *people*, and κρατειν, *to command, govern*.

The moſt flouriſhing democracies were thoſe of Rome and Athens; the modern republics, as Venice, and the United Provinces, are rather ariſtocracies than democracies. The government of Baſil, however, is a democracy; and ſo are ſome of the free cities in Germany. In a democracy, where the right of making laws reſides in the people at large, public virtue, or goodneſs, is more likely to be found than either of the other qualities of government; and therefore it uſually poſſeſſes a conſiderable degree of patriotiſm and public ſpirit. Democracies are uſually the beſt calculated to direct the end of a law; Ariſtocracies to invent the means by which that end ſhall be obtained; and Monarchies to carry thoſe means into execution.

DEMONSTRABLE, a term uſed in the ſchools, to ſignify ſomewhat that may be clearly and evidently proved. It is demonſtrable, that the ſide of a ſquare is incommenſurable with the diagonal.

DEMONSTRATION, in logic, a ſeries of ſyllogiſms, all whoſe premiſes are either definitions, ſelf-evident truths, or propoſitions already eſtabliſhed. See LOGIC.

DEMONSTRATIVE, in rhetoric, uſed for proving or rendering any thing ſelf evident, beyond contradiction, or ſo as to demand aſſent.

DEMONSTRATIVE, in grammar, applied to pronouns which ſerve to ſhew, point out, or indicate a thing: as, *this*, *that*, *thoſe*, &c. They are alſo called definitive, becauſe they define and limit the extent of the common name, or general term, to which they either refer, or are joined.

DEMURRER, in law, a ſtop put to any action upon ſome point of difficulty which muſt be determined by the court, before any further proceedings can be had in the ſuit.

DEN, a ſyllable added to the names of places, and ſhews their ſituation to be in a valley, or near woods, as Tenterden, Biddenden, &c. The word is Saxon, *den*, i. e. *vallis*, or *locus ſylveſtris*.

DENARIUS, in Roman antiquity, the chief ſilver coin among the Romans, worth in our money about ſeven-pence three farthings. As a weight, it was the ſeventh part of a Roman ounce.

DENARIUS is alſo uſed in our law-books for an Engliſh penny.

DENDRACHATES, in natural hiſtory, the name uſed by the ancients for an extremely elegant and beautiful ſpecies of agate, the ground of which is whitiſh, variegated with veins of a brighter white. Theſe veins are beautifully diſpoſed in a number of various figures; but generally in many concentric irregular circles, drawn round one or more points. It is common alſo, in various parts of this ſtone, to find very beautiful delineations of trees, moſſes, ſea-plants, and the like, ſo elegantly expreſſed, that many have erroneouſly taken them for real plants included in the ſubſtance of the ſtone; whence the name dendrachates.

DENDROMETER, from δενδρον, *a tree*, and μετρεω, *I meaſure*, an inſtrument invented by Meſſrs. Duncombe and Whittel; for which they obtained a patent, ſo called from its uſe in meaſuring trees. See Syſtem of GEOMETRY.

DENIER, the French penny; a ſmall copper coin, twelve whereof make a ſol, or French ſhilling. The French *denier* is about the twenty-third part of the Engliſh penny. There are two kinds of *deniers:* the one Tournois, the other Pariſian; whereof the latter was worth a fourth part more than the former, and was called *monnoy royale*, or *fort monnoye*, and ſometimes *denier d'or*, and *denier à valeur d'or*.

DENIZEN, in law, an alien made a ſubject by the king's letters patent; otherwiſe called *donaiſon*, becauſe "his legitimation proceeds *ex donatione regis*, from the king's gift."

DENOMINATION, from *denomino*, of *de* and *nomen*, *a name*; a name impoſed on any thing, uſually expreſſing ſome quality predominant therein. Hence, as the qualities and forms of things are of two kinds, viz. internal and external, denomination becomes two-fold.

Internal DENOMINATION, is that founded on the intrinſic form: thus Peter is denominated learned on account of his learning, which is ſomething internal.

External DENOMINATION, is that founded on, or ariſing from the external form. Thus, a wall is ſaid to be ſeen, and known, from the viſion and cognition employed upon it; and thus Peter is denominated honoured, by reaſon of honour, which is not in the perſon honoured, but in him that honours.

DENOMINATOR, in arithmetic, a term only uſed in ſpeaking of fractions, or broken numbers. See Syſtem of ARITHMETIC, Art. X.

DENSITY, *Denſitas*, that property or habitude of bodies whereby they contain ſuch a quantity of matter, under ſuch a bulk. Accordingly, a body that contains more matter than another, under the ſame bulk, is ſaid to be denſer than the other. Denſity ſtands in oppoſition to rarity. Hence, ſince the maſs is proportional to the gravity, a denſer body is ſpecifically heavier than a rarer; and a ſpecifically heavier is denſer than a ſpecifically lighter.

Density *of the Air* is a property that has much employed the late philoſophers, ſince the diſcovery of the Torricellian experiment, and the air pump. See Syſtem of Pneumatics.

DENTAL, *Dentalis*, from *dens, a tooth*, is applied to certain letters, in the pronunciation whereof the teeth have a principal ſhare. Grammarians, and eſpecially the Hebrew ones, diſtinguiſh the letters into *dental, labial, guttural, lingual, palatal*, &c.

DENTALIUM, a ſhell-fiſh belonging to the claſs of vermes, and the order of teſtacea. The ſhell conſiſts of one tubulous ſtraight valve, open at both ends. There are eight ſpecies, diſtinguiſhed by the angles, ſtriæ, &c. of their ſhells. See Syſtem of Conchology, Genus 33.

DENTARIA, tooth wort, or tooth violet; a genus of the ſiliquoſa order, belonging to the tetradynamia claſs of plants. There are three ſpecies, all of them hardy perennials; producing annual ſtalks 12 or 18 inches high, adorned with many-lobed leaves, and ſpikes of quadrupetalous cruciform flowers of a red or purple colour. See Syſtem of Botany, Sect. V. and Plate V.

DENTEX, in *Ichthyology*, the name of a ſea-fiſh, caught in great plenty in the Mediterranean, and common in the markets of Italy. The teeth are diſpoſed in a ſingle row in each jaw, and there are at diſtances, four, which are longer and broader than the reſt, and look like the canine teeth of men, or of quadrupeds: it is from theſe that it has its name, and theſe as well as the reſt of the teeth are in this fiſh covered with lips, as in quadrupeds; its tail is forked, and its ſcales are very large.

DENTICLES, or Dentils, in architecture, an ornament in cornices, bearing ſome reſemblance to teeth; particularly affected in the Ionic and Corinthian orders; and of late alſo in the Doric. See Syſtem of Architecture. Ionic Order, Plate VI.

DENTIFRICE, from *dens*, a *tooth*, and *frico, I rub*, in medicine, tooth powder; a remedy to rub the teeth, in order to cleanſe, or faſten them. There are various kinds; generally made of earthy ſubſtances finely pounded, and mixed with alum, or ſome other ſaline ſubſtances: but theſe are pernicious, on account of their wearing away the enamel of the teeth; but more eſpecially by the ſeptic quality with which theſe earthy ſubſtances are endowed. On this account, a portion of Peruvian bark finely pounded is now commonly added, which anſwers the double purpoſe of cleaning the teeth, and preſerving them afterwards from corruption.

DENTISCALPRA, from *dens, tooth*, and *ſcalprum, ſcraping, inſtrument*, in ſurgery, an inſtrument for ſcouring yellow, livid, or black teeth; to which being applied near the gums, it ſcrapes off the foul morbid cruſt. Some of theſe inſtruments are furniſhed with narrow points; others with broader, and with edges; and ſome again are falciform; but all of them adapted to one and the ſame handle.

DENTITION, *Dentitio*, the act of cutting the teeth, in children. See Syſtem of Medicine.

DENUNCIATION, *Denunciatio*, a ſolemn publication, or promulgation of any thing. All veſſels of enemies are lawful prize after *denunciation*, or proclamation of war. The deſign of the *denunciation* of excommunicated perſons is, that the ſentence may be the more fully executed; that the perſons may be known.

DEOBSTRUENTS, from *de*, and *obſtruo, I obſtruct*, are ſuch medicines as open obſtructions. There is ſomething farther intimated by *deobſtruent* than by *detergent*; for a medicine may be *deobſtruent* that is not in the ſtricteſt ſenſe *detergent*: as, in effect, are moſt of thoſe which are made of metalline ſubſtances, ſuch as ſteel and mercury; which obtain the appellation *deobſtruents* from their acting by their natural weight, whereby they increaſe the momentum of the circulating fluid, and make it ſtrike againſt the ſecretory outlets with greater force; becauſe the momentum, or *vis percuſſionis*, of all projectiles, of which kind is a circulating fluid, is as their ſolidities, ſuppoſing their velocities equal. The more, therefore, the animal fluids are ſaturated with denſe and ſolid particles, with the greater force they diſtend the veſſels, and the more eaſily break through, where the ſtructure favours their eſcape; and upon that account are medicines which add to theſe qualities in the fluids called *deobſtruents*.

DEPART, a method of refining, or ſeparating gold from ſilver by means of *aqua fortis*.

There are three ways of refining gold; the firſt by antimony, the ſecond by ſublimate; and the third, which is the moſt uſual, by *aqua fortis*. Refining.

DEPARTMENT, in juriſprudence, ſignifies diſtribution, diviſion, or allotment of certain employments among ſeveral perſons. Thus the great officers of ſtate, &c. have each their ſeveral departments: and the buſineſs of the ſecretaries of ſtate in particular, is generally divided into two partitions; the one officiating for the ſouthern, the other for the northern department: though ſometimes another is added on particular occaſions.

Department, in architecture, that part of an edifice, deſtined for ſome peculiar purpoſe: as in a palace, the department of the kitchen, of the ſtables, &c.

DEPARTURE, or Departer, in law, a term properly applied to a perſon, who firſt pleading one thing in bar of an action, and that being replied to, waves it, and inſiſts on ſomething different from his firſt plea. Or, it may be applied to a plaintiff, who in his replication ſhews a new matter different from that in his declaration. So if a man plead a general agreement in bar, and in his rejoinder allege a ſpecial one, it ſhall be adjudged a departure in pleading. The defendant hereupon demurreth, becauſe it was a departure from the declaration. Coke, part ii. fol. 147.

Departure *in Deſpight of the Court*, is when the tenant, or defendant, after appearing to the action brought againſt him, and having a day over in the ſame term, does not appear at the day, but makes a default. This is *departure in deſpight of the court*; and therefore he ſhall be condemned.

Departure, in navigation, is the eaſting, or weſting of a ſhip, with reſpect to the meridian from which it departed or ſailed. Or, it is the difference of longitude, either eaſt or weſt, between the preſent meridian the ſhip is under, and that where the laſt reckoning or obſervation was made. This departure, any where but under the equator, muſt be accounted according to the number of miles in a degree proper to the parallel the ſhip is under.

DEPHLEGMATION, in chymiſtry, is the act of purifying, or clearing a fluid of its phlegm, or water. This is performed either by evaporation, or by diſtilling the ſpirit, or other fluid, ſeveral times; by which means the ſpirituous part ariſes, and leaves the phlegm, or, at leaſt, as much as it can be, it is called a dephlegmated ſpirit.

DEPILATORY *Medicines*, thoſe applied in order to take off the hair: ſuch are lime and orpiment known to be, but which ought to be uſed with great caution. The word is formed of the particle *de*, and *pilus, hair*.

DEPONENT, *Deponens*, in the Latin Grammar, a term applied to verbs which have active ſignifications, but paſſive terminations, or conjugations, and want one of their participles paſſive. They are called *deponents*, as having depoſited, or laid aſide their paſſive ſignification.

Deponent, in a legal ſenſe, a perſon who makes a depoſition or affidavit.

DEPOPULATION, the act of waſting, deſtroying, deſolating, or unpeopling a place. Coke, Inſtitut. part iii. fol. 204.

DEPOSIT, among civilians, ſomething that is committed to the cuſtody of a perſon, to be kept without any reward, and to be returned again on demand. The civilians divide *depoſitum* into *ſimple* and *judiciary*.

Judiciary Deposit, is that whoſe property is conteſted between ſeveral perſons, and depoſited in the hands of ſome third perſon, by decree of a judge.

Simple Deposit, is either voluntary, or neceſſary. Neceſſary is that done in caſe of hoſtility, ſhipwreck, fire, &c. Innholders are reſponſible for the baggage brought to them, as being a neceſſary depoſit.

DEPOSITIO, in grammar, is a name which the Latins gave to the final cadence, which terminates, as it were, the meaſure of the verſe. The Greeks call it αποθεσιν, and καλαλεξιν. Hence ariſeth the diſtinction of verſe into four ſpecies, viz. *acatalectic, catalectic, brachycatalectic* and *hypercatalectic*.

DEPOSITION, in law, a teſtimony given in court by a witneſs upon oath. In chancery, depoſition is a teſtimony ſet down in writing, by way of anſwer to the interrogatories exhibited in chancery, where ſuch witneſs is called *deponent*.

Deposition is alſo uſed for the ſequeſtering, or depriving a perſon of his dignity and office. This depoſition only differs from abdication, in that the latter is ſuppoſed voluntary, and the act of the dignitary, or officer himſelf; and the former of compulſion, being the act of a ſuperior power, whoſe authority extends thereto. Some ſay the depoſition, and ſome the abdication of king James II. Depoſition does not differ from deprivation; we ſay indifferently, a depoſed, or deprived biſhop, official, &c. Depoſition differs from ſuſpenſion, in that it abſolutely and for ever ſtrips or diveſts a prieſt, &c. of all dignity, office, &c. whereas ſuſpenſion only prohibits or reſtrains, the exerciſe thereof.

DEPOT, in military language, denotes a particular place at the tail of the trenches, out of the reach of the cannon of the place, where the troops commonly aſſemble, that are ordered either to attack the outworks, or to ſupport the troops in the trenches, when there is reaſon to imagine that the beſieged intend to make a vigorous attack.

Depot alſo ſignifies a temporary magazine for forage, faſcines, gabions, tools, &c. neceſſary for the ſupport of an army, or for carrying on a ſiege.

DEPRECATION, from *deprecor, I intreat*, in rhetoric, a figure whereby the orator invokes the aid or aſſiſtance of ſome one; or prays for ſome great evil or puniſhment to befall him who ſpeaks falſely, either himſelf, or his adverſary.

DEPRESSION *of the Pole*. So many degrees as you ſail, or travel from the pole towards the equator, ſo many you are to depreſs

preſs the pole, becauſe it becomes reſpectively, ſo much lower, or nearer the horizon.

Depression *of the viſible Horizon*, denotes its ſinking or dipping below the true horizontal plane; whether cauſed by ſome variation of the atmoſphere, or by different height of the obſerver's eye above the ſurface of the ſea. See Robertſon's Elem. of Navigation, book ix. p. 391. and Tables requiſite to be uſed with the Nautical Ephemeris, p. 14.

Depression *of the Sun*, or *of a Star*, is its diſtance from the horizon, below it, meaſured by an arch of the vertical circle, intercepted between it and the horizon.

DEPRESSOR, in anatomy, a name common to divers muſcles, from their office in lowering, or bringing down, the parts they are faſtened to.

Depressor, *Alæ Naſi*, in anatomy, a name given by Albinus to a muſcle of the face, called by Cowper *conſtrictor alæ naſi*, and *depreſſor labii ſuperioris*. See Syſtem of Anatomy. Part III. Sect. IX.

Depressores *Oculi*, a pair of muſcles ſpringing from each corner of the eye, and anſwered by another pair of like figure and ſtructure in the lower eye-lid. Theſe are often conſidered together by anatomiſts as one orbicular muſcle; the fibres environing the eye-lids, and being inſerted into them, not unlike the ſphincters of other parts. See Syſtem of Anatomy. Plate of the Organs of Senſe. *Fig.* 10. *f.*

DEPRIVATION, in the canon law, the act of diveſting, or taking away a ſpiritual promotion, or dignity: as when a biſhop, vicar, prebend, or the like, is depoſed, or *deprived* of his preferment, for ſome matter, or fault, in fact, or in law.

DEPTH, the meaſure of any thing from the ſurface downwards.

Depth, *of a Sail*, denotes the extent of any ſquare or oblong ſail from the head-rope to the foot-rope; or the length of the after-leech of any boom-ſail or ſtay-ſail.

Depth *of a Squadron*, or *Battalion*, is the number of men in a file, or the number of ranks. Infantry is now generally drawn up three deep, and in the defence of a breaſt-work only two deep. The cavalry is commonly drawn up three deep, and ſometimes only two deep.

DEPURATION, from *depurgo, I purify*, in pharmacy, the ſame as clarification, or purification; viz. the purging a body of all the lees, fæces, and other craſs, coarſe, and excrementitious parts contained therein. Fermentation ſerves to *depurate* liquors: ſyrups, juices, &c. are *depurated* by paſſing them through the *minica hippocratis*, or ſtraining-bag.

DEPUTATION, from *deputare, to depute*, a miſſion of certain ſelect perſons out of a company, or body, to a prince, or aſſembly to treat of matters in their name, or to proſecute ſome affair therein. *Deputations* are more or leſs ſolemn, according to the quality of thoſe who ſend them, and the buſineſs they are ſent upon. *Deputation* is not properly applied where a ſingle perſon ſends another with ſuch commiſſion; but only where a body are concerned. The parliament *deputed* the ſpeaker, and ſix members, to preſent their addreſs to his majeſty. The chapter *deputed* two canons to ſolicit their affair in council.

DEPUTY, a perſon ſent, or deputed, by ſome community, in their name and behalf.

Deputy, in law, is one who exerciſes an office in another's right: and the forfeiture or miſdemeanor of ſuch deputy ſhall cauſe the perſon whom he repreſents to loſe his office. A ſuperior officer muſt anſwer for his deputy in civil actions, but not in criminal caſes. Judges have no power to hold their courts by deputy: recorders, however, may do it. Coroners cannot appoint deputies, becauſe theirs is a judicial office of truſt, annexed to their perſons. Sheriffs, ſtewards of a court, bailiffs of a liberty, and conſtables, are allowed to appoint deputies.

DERELICT is applied to ſuch lands, as the ſea receding from, leaves dry, and fit for cultivation. If they are left by a gradual receſs of the ſea, they are adjudged to belong to the owner of the adjoining lands: but when an iſland is formed in the ſea, or a large quantity of new land appears, ſuch derelict lands belong to the king.

DE REVOCATIONE *Parliamenti*, the name of a writ for recalling a parliament. Thus in 5 Edw. III. the parliament being ſummoned, was recalled by ſuch a writ before it met. Vide Pryn's Animad, on the 4 Inſt. f. 44.

DERIVATION, in grammar, the affinity one word has with another, by having been originally formed from it. See Derivative.

Derivation, in medicine, is when a humour which cannot conveniently be evacuated at the part affected, is attracted from thence, and diſcharged elſewhere: thus, a bliſter is applied to the neck to draw away the humour from the eyes.

The doctrine of derivation and revulſion ſo much talked of by the ancients is, in their ſenſe of theſe terms, wholly exploded. By revulſion, they meant the driving back of the fluids from one part to another. The only rational meaning the word *revulſion*, as here applied, can have, is, the preventing too great an afflux of humours to any part, either by contracting the area of the veſſels, or diminiſhing the quantity of what flows from them; the firſt of theſe intentions is anſwered by the application of repellents to the part; the laſt by bleeding, and other evacuations: thus, any medicines promoting the ſecretions, may be ſaid to make a revulſion; and in this ſenſe derivation can only be underſtood.

DERIVATIVE, in grammar, a word which is derived from another called its *primitive*. Thus, *manhood* is derived from *man*; *Deity* from *Deus*.

DERMA, in anatomy, the cutis, or ſkin of an animal; or the tegument inveſting the whole body immediately under the cuticle, or ſcarf-ſkin. The word comes from the Greek δερειν, *to flay*, or *excoriate*. The derma conſiſts of two parts; the *corpus reticulare*, and *papillæ pyramidales*.

DERMESTES, in entomology, a genus of inſects of the order of the coleoptera, the antennæ of which are of a clavated figure, and perfoliated tranſverſely. There are ſeveral ſpecies of this genus, confounded by ſome with beetles, or ſcarabæi.

DEROGATION, an act contrary to a preceding one, and which annuls, deſtroys, and revokes it, either in whole or in part.

DEROGATORY, a clauſe importing derogation. A derogatory clauſe in a teſtament, is a certain ſentence, cipher, or ſecret character, which the teſtator inſerts in his will, and of which he reſerves the knowledge to himſelf alone, adding a condition, that no will he may make hereafter is to be reckoned valid, if this derogatory clauſe is not inſerted expreſly and word for word. It is a precaution invented by lawyers againſt latter-wills extorted by violence, or obtained by ſuggeſtion.

DERVIS, or Dervich, a name given to a ſort of monks among the Turks, who lead a very auſtere life, and profeſs extreme poverty; they are allowed to marry. The word is originally Perſian, דרויש, ſignifying a *beggar*, or perſon who has nothing: and becauſe the religious, and particularly the followers of Mevelava, profeſs not to poſſeſs any thing, they call both the religious in general, and the Mevelavites in particular, Derviſes, or Derviches. The Derviſes affect a great deal of modeſty, patience, humility, and charity. They always go bare-legged, and open-breaſted, and frequently burn themſelves with hot irons, to inure themſelves to patience. They always faſt on Wedneſdays, eating nothing on thoſe days till after ſun-ſet. Tueſdays and Fridays they hold meetings, at which the ſuperior of the houſe preſides. One of them plays all the while on a flute, and the reſt dance, turning their bodies round and round with the greateſt ſwiftneſs imaginable. Long cuſtom to this exerciſe from their youth has brought them to ſuch a habitude, that it does not diſcompoſe them at all. This practice they obſerve with great ſtrictneſs, in memory of Mevelava their patriarch's turning miraculouſly round, as they pretend, for the ſpace of four days, without any food or refreſhment, his companion Hamſa playing all the while on the flute; after which he fell into an extaſy, and therein received wonderful revelations for the eſtabliſhment of his order. They believe the flute an inſtrument conſecrated by Jacob, and the ſhepherds of the Old Teſtament, becauſe they ſang the praiſes of God upon them. They profeſs poverty, chaſtity, and obedience, and really obſerve them while they remain derviſes; but if they chooſe to go out, and marry, they are always allowed.

The derviſes are great travellers; and, under pretence of preaching, and propagating their faith, are continually paſſing from one place to another: on which account they have been frequently uſed as ſpies. There are alſo derviſes in Perſia, called in that country Abdals, q. d. *ſervants of God*. They lead a very penurious, auſtere life, and preach the Alcoran in the ſtreets, coffee-houſes, and wherever they can meet with auditors. The Perſian derviſes retail little but fables to the people, and are in the utmoſt contempt among the men of ſenſe, and letters. There are in Egypt two or three kinds: thoſe that are in convents, are in a manner of the religious order, and live retired; though there are of theſe ſome who travel and return again to their convents. Some take this character, and yet live with their families, and exerciſe their trades: of this kind are the dancing derviſes at Damaſcus, who go once or twice a week to a little inhabited convent, and perform their extraordinary exerciſes: theſe alſo ſeem to be a good people: but there is a third ſort of them who travel about the country, and beg, or rather oblige people to give; for whenever they ſound their horn ſomething muſt be given them. The people of theſe orders, in Egypt, wear an octagonal badge, of a greeniſh white alabaſter, at their girdles, and a high ſtiff cap without any thing round it. Pococke's Egypt, p. 178.

DESART, or Desert, a wild, uncultivated, uninhabited place or country: as the deſarts of Lybia, of the Thebaid, &c. Geographers uſe the word in the general for all countries little, or not at all, inhabited. In Scripture, we find ſeveral places in the Holy Land, or places adjoining thereto, called deſart. The deſart, or wilderneſs, abſolutely ſo called, is that part of Arabia on the ſouth of the Holy Land, wherein the Iſraelites wandered, from the time of their evacuating Egypt to their entry into the Promiſed Land. Whence the Hebrews call them by antiphraſis מרבר, which properly ſignifies *human word*, or *ſpeech*, becauſe there is none heard there.

DESCENDANT, in genealogy, a term relative to aſcendant, and applied to a perſon who is born or iſſued from ſome other referred to. Thus, mankind are ſaid to be deſcendants of Adam.

The deſcents from the brothers of the Maid of Orleans are confirmed in the exemption from all taxes and impoſts, by a regulation of the year 1634.

DESCENDING, ſomething that falls, or moves, from above, downwards. There are *aſcending* and *deſcending* ſtars; and *aſcending* and *deſcending* degrees. There are alſo *aſcending* and *deſcending* veins ſpringing out of the *cava;* and *aſcending* and *deſcending* arteries riſing out of the *aorta*.

Descending *Latitude*, is the latitude of a planet in its return from the modes to the equator. *Deſcending* in heraldry is when the head of the beaſt is turned downward to the baſe of the ſhield.

DESCENSION, in aſtronomy, is either *right* or *oblique*.

Right **Descension** *of a Star*, or *Sign*, is a point, or arch, of the equator, which *deſcends* with the ſtar, or ſign, below the horizon, in a right ſphere.

Oblique **Descension**, is a point, or arch, of the equator, which *deſcends* at the ſame time with a ſtar, or ſign, below the horizon, in an oblique ſphere.

DESCENT, in chemiſtry. The ſeparating mercury from its ore by *deſcent*, is performed in the following manner: take two earthen pots, with orifices of equal diameter: adapt an iron plate to the orifice of one of the two pots, in ſuch a manner that it may reſt upon the brink of it, but not jut out too much all round: let this have ſeveral holes bored here and there in it, but not near its bottom; pour into this pure water, to about two inches high, then ſhut it with the iron plate; put upon this plate a ſmaller veſſel, containing the ore of mercury; then cloſe theſe veſſels, with the ſecond pot inverted, ſtopping the joint well with lute; bury the inferior pot in aſhes, and put about the whole a moderate fire, continue it till the upper veſſel is ſlightly red hot, and the mercury will be driven into the lower, in fumes, which will be condenſed by the water into running quickſilver. Cramer's Art of Aſſaying, p. 352.

Descent, *into a Ditch*, in fortification, is a deep trench, or ſap, cut through the eſplanade, and under the couvert-way; covered above with planks and hurdles, and loaded with earth againſt artificial fires.

In wet ditches the deſcent is made even to the ſurface of the water; in dry ditches, it is carried to the bottom of the moat, where traverſes are made to lodge and ſecure the mines.

Descent, in geneaology, heraldry, and the order, or ſucceſſion, of deſcendants in a line, or family.

Descent is alſo uſed, in heraldry, to expreſs the coming down of any thing from above. Thus, a *lion en deſcent* is a lion with his head towards one of the baſe points, and his heels towards one of the corners of the chief; as if he were leaping from ſome high place.

Descent, or **Discent**, in law, the order, or manner, wherein lands and tenements are derived to any man from his anceſtors; and this is by cuſtom, ſtatute, or common law. By cuſtom, as in GAVELKIND or BOROUGH Engliſh: by ſtatute, as in FEE TAIL; and by common law, when a perſon has lands of inheritance in fee-ſimple, and dies without diſpoſing them; in which caſe the land deſcends in courſe to the eldeſt ſon and heir. Thus, to *make his deſcent* from his anceſtors, is to ſhew how, and by what particular degrees, the land in queſtion came to a perſon from his anceſtors.

Descent, in common law, is either lineal, or collateral.

Lineal **Descent**, is that conveyed down, in a right line, from the grandfather to the father, and from the father to the ſon, from the ſon to the grandſon, &c.

Collateral **Descent**, is that ſpringing out of the ſide of the line, or blood; as from a man to his brother, nephew, or the like.

Fall **Descent**, in mechanics, &c. is the motion, or tendency, of a body towards the centre of the earth, either directly or obliquely. See Syſtem of MECHANICS.

Line of ſwifteſt **Descent**, is that which a body falling by the action of gravity, deſcribes in the ſhorteſt time; which is proved by geometricians to be the cycloid.

DESCRIPTION, in poetry and rhetoric, is a figure which by the aid of imagery and argument, exhibits ſuch a ſtrong and lively repreſentation of a ſubject, as gives a diſtinct view and ſatisfactory notion of it to the reader or hearer; and whilſt it convinces the mind, it moves and ſways the paſſions. This figure is principally uſed by poets, not only with a deſign to move the paſſions, but to pleaſe the fancy. Hiſtorians alſo deſcribe things, places, and perſons; and orators produce the greateſt effect by deſcription. The deſcription of a perſon is called a character.

DESERTER, from *deſero*, *I forſake*, in war, a ſoldier on the muſter-roll, who quits the ſervice without leave, or liſts himſelf under another officer, into a different regiment. All ſoldiers found half a league from a garriſon, or army, going towards an enemy's country, or quarter, without a paſs, are deemed and treated as deſerters. A deſerter is, by the articles of war, puniſhable by death, and after conviction is hanged at the head of the regiment he formerly belonged to, with his crime written on his breaſt; and is ſuffered to hang until the army leave that camp, for a terror to others. By the ancient laws of this kingdom, deſertion was deemed felony; but it is now puniſhed by courts martial, under the annual acts againſt mutiny and deſertion

DESHABILLE, a French term, naturalized of late. It properly ſignifies a night-gown, and other neceſſaries, made uſe of in dreſſing or undreſſing. Mr. ——— is not to be ſpoken with, he is yet in his *diſhabille*, i. e. undreſſed, or in his night-gown. The word is compounded of the privative *de*, and *s'habiller*, *to dreſs, one's ſelf*.

DECHAUSSEE', Fr. from *de* and *hacher*, *to cut*, in heraldry, is when a beaſt has its limbs ſeparated from the body, ſo as they ſtill remain on the eſcutcheon, with only a ſmall ſeparation from their natural places.

DESIDERATUM, from *deſidero*, *I deſire*, is uſed to ſignify deſirable improvements in any art or ſcience, as yet unattained. Thus, it is a *deſideratum* with the blackſmith, to render iron fuſible, by gentle heat, and yet preſerve it hard enough for ordinary uſes; with the glaſs-man and looking-glaſs-maker, to render glaſs malleable; with the clock-maker, to bring pendulums to be uſeful where there are irregular motions, &c. And though, as Mr. Boyle obſerves, the obtaining of theſe *deſiderata* may be thought chimerical, yet it is proper they ſhould be propoſed; for although perfection may not be attainable, yet approaches to it may be made, and arts thereby improved. Vide Boyle's Works abr. vol. i. p. 129, 136. In ſhort, all arts and ſciences have their defects, and it is not at firſt to be gueſſed, how many of theſe remedies may be found, by means of chymical and philoſophical reſearches properly directed.

DESIGN, from *deſigno*, *I mark out*, in a general ſenſe, the plan, order, repreſentation, or conſtruction of a building, book, painting, &c. See ARCHITECTURE, PAINTING, POETRY, ORATORY, HISTORY, &c. In building, we uſe the term ichnography, when by deſign is only meant the plan of a building, or a flat figure drawn on paper. Orthography, when ſome face or ſide of the building is raiſed from the ground. And ſcenography, when both front and ſides are ſeen in perſpective.

Design, in weaving manufactories, expreſſes the figures wherewith the workman enriches his ſtuff, or ſilk, and which he copies after ſome painter, or eminent draughtſman, as in diaper, damaſk, and other flowered ſilk and tapeſtry, and the like. In undertaking ſuch kinds of figured ſtuffs, it is neceſſary, ſays Monſ. Savary, that, before the firſt ſtroke of the ſhuttle, the whole deſign be repreſented on the threads of the warp, we do not mean in colours, but with an infinite number of little packthreads, which, being diſpoſed ſo as to raiſe the threads of the warp, let the workmen ſee, from time to time, what kind of ſilk is to be put in the eye of the ſhuttle for woof. This method of preparing the work is called *reading the deſign*, and *reading the figure*, which is performed in the following manner: A paper is provided, conſiderably broader than the ſtuff, and of a length proportionate to what is intended to be repreſented thereon. This they divide lengthwiſe, by as many black lines as there are intended threads in the warp; and croſs theſe lines, by others drawn breadthwiſe, which, with the former, make little equal ſquares: on the paper thus ſquared, the draughtſman deſigns his figures, and heightens them with colours as he ſees fit. When the deſign is finiſhed, a workman reads it, while another lays it on the ſimblot.

To read the deſign, is to tell the perſon who manages the loom, the number of ſquares, or threads, compriſed in the ſpace he is reading, intimating at the ſame time, whether it is ground or figure. To put what is read on the ſimblot, is to faſten little ſtrings to the ſeveral packthreads, which are to raiſe the threads named; and thus they continue to do till the whole deſign is read.

Every piece being compoſed of ſeveral repetitions of the ſame deſign, when the whole deſign is drawn, the drawer, to re-begin the deſign afreſh, has nothing to do but to raiſe the little ſtrings, with ſlip-knots, to the top of the ſimblot, which he had let down to the bottom: this he is to repeat as often as is neceſſary till the whole be manufactured.

The ribbon-weavers have likewiſe a deſign, but far more ſimple than that now deſcribed. It is drawn on paper with lines and ſquares, repreſenting the threads of the warp and woof. But inſtead of lines, whereof the figures of the former conſiſt, theſe are conſtituted of points only, or dots, placed in certain of the little ſquares, formed by the interſection of the lines. Theſe points mark the threads of the warp that are to be raiſed, and the ſpaces left blank denote the threads that are to keep their ſituation: the reſt is managed as in the former.

Design, is particularly uſed, in painting, for the firſt idea of a large work, drawn roughly, and in little, with intention to be executed, and finiſhed in large.

The qualities, or conditions, required in a deſign, are correctneſs, good taſte, elegance, character, diverſity, expreſſion, and perſpective.

Correctneſs depends principally on the juſtneſs of the proportions, and a knowledge of anatomy. Taſte is an idea, or manner of deſigning, which ariſes either from the complexion, and natural diſpoſition, or from education, one's maſter, ſtudies, &c. Elegance gives the figures a kind of delicacy which ſtrikes people of judgment, and a certain agreeableneſs which pleaſes every body. The character is what is peculiar to each thing, in which there muſt be a diverſity; inaſmuch as every thing has its peculiar character to diſtinguiſh it. The expreſſion is the repreſentation of an object according to its character, and the ſeveral circumſtances it is ſuppoſed to be in. The perſpective is the repreſentation of the parts of a painting, or figure, according to the ſituation they are in, with reſpect to the point of ſight.

The deſign, or draught, is a part of the greateſt import and extent in painting: it is acquired chiefly by habit and application, rules being of leſs avail here than in any of the other branches of the art, as colouring, clair-obſcure, expreſſion, &c. See Treatiſe on the Art of Drawing.

Design, in muſic, is juſtly defined by Rouſſeau to be the invention and the conduct of the ſubject, the diſpoſition of every part, and the general order of the whole.

It is not ſufficient to form beautiful airs, and a legitimate harmony; all theſe muſt be connected by a principal ſubject, to which all the parts of the work relate, and by which they became one. Thus unity ought to prevail in the air, in the movement, in the character, in the harmony; and in modulation. All theſe muſt indiſpenſably relate to one common idea which unites them. The greateſt difficulty is, to reconcile the obſervation of thoſe precepts with an elegant variety; which, if not introduced, renders the whole piece irkſome and monotonic. Without queſtion the muſician, as well as the poet, and the painter, may riſk every thing in favour of this delightful variety; if, under the pretext of contraſting, they do not endeavour to cheat us with falſe appearances, and inſtead of pieces juſtly and happily planned, preſent us with a muſical minced meat, compoſed of little abortive fragments, and of characters ſo incompatible, that the whole aſſembled forms an heterogeneous monſter.

Non ut placidis cœant immitia, non ut
Serpentes avibus geminentur, tigribus agni.

Tranſlated thus:

But not that nature ſhould revers'd appear;
Mix mild with fierce, and gentle with ſevere;
Profane her laws to contradiction's height;
Tygers with lambs, with ſerpents birds unite.

It is therefore in a diſtribution formed with intelligence and taſte, in a juſt proportion between all the parts, that the perfection of deſign conſiſts; and it is above all, in this point, that the immortal Pergoleſo has ſhown his judgment and his taſte, and has left ſo far behind him all his competitors. His *Stabat Mater*, his *Orfeo*, his *Serva Padrona*, are, in three different ſpecies of compoſition, three maſter pieces of deſign equally perfect.

DESIGNATION, the act of marking or indicating, and making a thing known. The deſignation of ſuch an eſtate is made by the tenants, butments, and boundings.

DESIGNING, the art of delineating, or drawing the appearance of natural objects, by lines, on a plain. To deſign, according to the rules of mathematics, makes the object of perſpective. See the Syſtem of Perspective.

DESPOT, a term uſed for an abſolute prince. See the next Article.

DESPOTISM, or Despotic *Government*, a form of government wherein the prince is abſolute and arbitrary, doing whatever he liſts, without being checked by any other power. Such are moſt of the Eaſtern governments; as thoſe of the mogul, grand ſignior, ſophi of Perſia, &c.

DESPUMATION, of *de*, priv. and *ſpuma*, *froth*, the clarification of any liquor, by throwing up its foulneſs in a froth, and taking that off.

DESQUAMATION, from *de*, and *ſquamo*, *I ſcale*, expreſſes the flaking or ſcaling of carious bones.

DESSERT, or Desart, Fr. the laſt ſervice brought on the tables of people of quality, when the meats are all taken off. The *deſſert* conſiſts of fruits, confectionary, &c.

DESICCATIVE, or Desiccative, from *deſicco*, *I dry up*, in medicine, a remedy that has the virtue of drying up ſuperfluous moiſture; uſed to ſkin over old ſores, &c. We ſay, a deſiccative unguent, &c.

DESTINIES, in mythology. See Parcæ.

DESTINY, from *deſtino*, *I order*, the order, diſpoſition, or chain of ſecond cauſes appointed by providence; and importing, or carrying with it, a neceſſity of event. According to many of the heathen philoſophers, deſtiny was a ſecret and inviſible power, or virtue, which, with incomprehenſible wiſdom, conducted what to us appears irregular and fortuitous. This amounts to what we call God.

The ſtoics, by deſtiny, underſtood a certain concatenation of things, which, from all eternity follow each other of abſolute neceſſity, there being no power able to interrupt their connexion. This anſwers, in a great degree, to our idea of providence. But the ſtoics made even the gods themſelves ſubject to the neceſſity of this deſtiny. The truth is, the ſtoics rather define what the word deſtiny ſhould ſignify, than what it did ſignify in common language; for they had no diſtinct idea of this power, to which they attributed thoſe events. They had only a vague, confuſed idea of I know not what chimera, or unknown cauſe, to which they referred that invariable diſpoſition, and the eternal concatenation of all things. There is no real being that the name deſtiny can agree to. The heathen philoſophers, who had framed a notion thereof, ſuppoſed it to exiſt, without knowing preciſely what they meant by it. But men, not daring on the one ſide to impute to providence the evils and misfortunes that befel them, as they imagined, undeſervedly; and, on the other ſide, not being willing to allow that it was their own fault, formed this phantom of deſtiny, to bear the weight of all the evil.

DESTRUCTION, the act of ruining, deſtroying, demoliſhing, or laying waſte; the ſtate of a thing ruined, demoliſhed, or deſtroyed.

DESUDATION, from *deſudo*, *I ſweat much*, expreſſes a profuſe and inordinate ſweating, followed by the irruption of Sudamina, or heat-pimples.

DETACHED *Pieces*, in fortification, are demilunes, ravelins, horn and crown works, and even baſtions, when ſeparated, or at a diſtance from the body of the place.

DETACHMENT, from the French *detacher*, *to part from*, a military term, ſignifying a certain number of ſoldiers, taken our of ſeveral regiment or companies equally, to be employed in ſome particular enterprize; as to form a kind of flying camp, to relieve a party already engaged in battle, to join a ſeparate army, to aſſiſt at the ſiege of a place, or to enter into ſome garriſon. The number depends on the dignity of the officer in command; thus, two thouſand or three thouſand men form a detachment for a general officer, eight hundred for a colonel, five hundred for a lieutenant-colonel, two or three hundred for a major, eighty or a hundred for a captain, forty for a lieutenant or enſign, twelve for a ſerjeant, and ſix for a corporal.

Detachment *of a Fleet or Squadron*, a certain number of ſhips choſen by an admiral or commodore from the reſt of the fleet, and charged to execute ſome particular ſervice.

DETENTION, from *detineo*, *I detain*, the poſſeſſion, or holding of lands, or the like, from ſome other claimant. The word is chiefly uſed in an ill ſenſe, for an unjuſt with-holding, &c. The canons condemn a perſon who has intruded into a benefice, to make reſtitution of all the fruits thereof, during the time of his unjuſt detention.

DETENTS, in a clock, are thoſe ſtops, which by being lifted up or let fall down, lock and unlock the clock in ſtriking.

Detent *Wheel*, or Hoop *Wheel*, in a clock, that wheel which has a hoop almoſt round it, wherein there is a vacancy, at which the clock locks.

DETERGENT, from *detergo*, *I cleanſe*, in medicine, is applied to remedies that cleanſe, and carry off viſcid and glutinous humours.

The plant buckthorn deterges, and conſolidates wounds. Rhaponticum is aperitive, and good againſt the gravel and ſtone: it alſo deterges, and expels poiſon. Detergents are not only ſoftening and adheſive, but alſo, by a peculiar activity, or diſpoſition to motion, joined with a ſuitable configuration of parts, are apt to abrade, and carry along with them, ſuch particles as they lay hold of in their paſſage. All medicines of this intention are ſuppoſed to cleanſe and heal, that is, incarnate, or fill up with new fleſh, all ulcerations and foulneſſes occaſioned thereby, whether internal or external. To do this, in all internal caſes eſpecially, the medicine muſt be ſuppoſed to maintain its primary properties, until it arrives at the place of action: and there it does what entitles into the appellation of a detergent, and a vulnerary: firſt, by its adheſive quality, which conſiſts in the comparative largeneſs of ſurface, and flexibility of its component parts, by which it readily falls into contact with, and adheres to, the ſlough of ulcerous exudations, which, by their looſe ſituations, are eaſily carried along with the medicine; and when ſuch matter is ſo carried away, which is the cleanſing and deterging part, what was inſtrumental in this office, will afterwards ſtick and adhere to the cutaneous filaments, until, by their addition, and the protruſion of proper nouriſhment, *ab interno*, to the ſame place, the waſte is made up, that is, the ulcer is healed.

After the like manner is the operation of detergents to be accounted for in external application. By the warmth of their parts they rarefy, and by their adheſive quality they join with, and take off along with them, in every dreſſing, what is thrown upon the place to which they are applied, until a more convenient matter is brought thither by the circulating juices, which they aſſiſt in adhering to, and incarnating the eroded carities. Only this may be taken notice of, that internally, whatſoever of this kind is mixed with the animal fluids, by the known laws of circulation, will be firſt ſeparated, and left behind; for all thoſe parts which are ſpecifically heavieſt, will move neareſt the axis of the canals, becauſe their moments are the greateſt, and will carry them, as near as can be, in ſtraight lines; but the lighter parts will always be driven to the ſides, where they ſooneſt meet with outlets to get quite off, or are ſtruck into ſuch cavities as we are here ſpeaking of, in which they adhere, and make part of the ſubſtance.

DETERIORATION, the impairing or rendering a thing worſe: it is juſt the reverſe of Melioration.

DETERMINATE *Problem*, is that which has but one, or at leaſt but a certain number of ſolutions; in contradiſtinction to an indeterminate problem, which admits of infinite ſolutions.

Such e. gr. is the problem, To deſcribe an iſoſceles triangle on a given line, whoſe angles at the baſe ſhall be double that at the vertex: which has only one ſolution; as that which follows has two, viz. To find an iſoſceles triangle, whoſe area and perimeter are given. A determinate problem may either be ſimple or linear, plane, ſolid, or ſurſolid.

DETERMINATION, in mechanics, ſignifies much the ſame with the tendency or direction of a body in motion.

Determination is alſo uſed for the action whereby a cauſe or agent is limited, or reſtrained, to act, or not act, in this or in that manner.

A determination to be pleaſed with certain forms, or ideas, an ingenious author calls an internal ſenſe; and a determination to be pleaſed with virtuous actions, characters, manners, &c. a moral ſenſe.

DETERRATION, from *de* and *terra*, is uſed to ſignify a removal of the earth, ſands, &c. from the mountains and higher grounds, down into the valleys and lower parts. This is occaſioned by rains, which waſh the earthy matter down by degrees; but this cannot be very conſiderable, or much raiſe the ſurface of the earth, as ſome have imagined, becauſe a good part of it is ſunk into the clefts and caverns of the rocks and mountains, a great quantity is borne down into rivers, and thence into the ſea, and the richer and finer parts help to compoſe the bodies of plants and vegetables.

DETERSIVES, in medicine, the ſame with detergent. A clyſter is a deterſive medicine, which cleanſes the lower venter. Deterſive unguents are alſo called mundificatives. The leaves and ſummits of the ſtrawberry are deterſive and aſtringent.

DETINUE, in law, a writ or action that lies againſt one who has got goods or other things delivered to him to keep, and afterwards refuſes to deliver them. In this action, the thing detained is generally to be recovered, and not damages; but if one cannot recover the thing itſelf, he ſhall recover damages for the thing, and alſo for the detainer. Detinue lies for any thing certain and valuable, wherein one may have a property or right as for a horſe, cow, ſheep, hens, dogs, jewels, plate, cloth, bags of money, ſacks of corn, &c. It muſt be laid ſo certain, that the thing detained may be known and recovered: and therefore, for money out of a bag, or corn out of a ſack, it lies not; for the money or corn cannot in this caſe be known from other money or corn; ſo that the party muſt have an action on the caſe, &c. Yet detinue may be brought for a piece of gold of the price of 22s. though not for 22s. in money.

Detinue *of Charters*. A man may have *detinue* for deeds and charters concerning land: but if they concern the freehold, it muſt be in C. B. and no other court. Action of *detinue* lies for charters which make the title of lands: and the heir may have *detinue* of charters, although he hath not the land. If my father be diſſeiſed, and dieth, I ſhall have *detinue* for the charters, notwithſtanding I have not the land; but the executors ſhall not have the action for them. New Nat. Br. 308.

Detinue *of Goods in Frank-Marriage*, is on a divorce betwixt a man and his wife; after which the wife ſhall have this writ of *detinue*, for the goods given with her in marriage. Mich. 35 Eliz. 1. New Nat. Br. 308.

DETONATION, in chymiſtry, ſignifies an exploſion with noiſe made by the ſudden inflammation of ſome combuſtible body: Such are the exploſions of gun-powder, fulminating gold, and fulminating powder. As nitre is the cauſe of moſt exploſions, the word *detonation* has been appropriated to the inflammation of the acid of this ſalt with bodies containing phlogiſton; and it is frequently given to thoſe inflammations of nitrous acid which are not accompanied with exploſion. Thus nitre is ſaid to detonate with ſulphur, with coals, with metals; although in the ordinary method of making theſe operations, that is, in open crucibles, and with ſmall quantities of detonating ſubſtances, the nitre does not truly explode. See Nitre.

DETRANCHE', among the French heralds, ſignifies a line bendwiſe, which does not come from the very dexter angle, but either from ſome part of the upper edge, and thence falling athwart, or diagonally; or form part of the dexter ſide. They ſay, *tranché*, *detranché*, and *retranché*; to denote, that there are two diagonal lines, making two partitions in the eſcutcheon, and coming from the angles, and a third from ſome of the other parts above mentioned.

DEUCALION, king of Theſſaly. The flood ſaid to have happened in his time, (1500 C.), was no more than an inundation of Theſſaly, occaſioned by heavy rains, and an earthquake that ſtopped the courſe of the river Peneus, where it uſually diſcharged itſelf into the ſea. On theſe circumſtances the fable of Deucalion's flood is founded. According to the fable, he was the ſon of Prometheus. He governed his people with equity; but the reſt of mankind being extremely wicked, were deſtroyed by a flood, while Deucalion and Pyrrha his queen ſaved themſelves by aſcending mount Parnaſſus. When the waters were decreaſed, they went and conſulted the oracle of Themis, on the means by which the earth was to be repeopled; when they were ordered to veil their heads and faces, to unlooſe their girdles, and throw behind their backs the bones of their great mother. At this advice Pyrrha was ſeized with horror: but Deucalion explained the myſtery, by obſerving, that their great mother muſt mean the earth, and her bones the ſtones; when taking them up, thoſe Deucalion threw over his head became men, and thoſe thrown by Pyrrha, women.

DEVICE, in painting. See Deviſe.

DEVIL, an evil angel, one of thoſe celeſtial ſpirits caſt down from heaven for pretending to equal himſelf with God. The Ethiopians paint the devil white, to be even with the Europeans who paint him black. There is no mention of the word *devil* in the Old Teſtament, but only of the word Satan and Belial; nor do we meet with it in any heathen authors, in the ſenſe it is taken among Chriſtians, that is, as a creature revolted from God. Their theology went no farther than to evil genii, or dæmons. Some of the American idolaters have a notion of two collateral independent beings, one of whom is good, and the other evil; which laſt they imagine has the direction and ſuperintendance of this earth, for which reaſon they chiefly worſhip him: whence thoſe that give us an account of the religion of theſe ſavages give out, with ſome impropriety, that they worſhip the devil. The Chaldeans, in like manner, believed both a good principle and an evil one; which laſt they imagined was an enemy to mankind. Iſaiah, ſpeaking, according to ſome commentators, of the fall ot the devil, calls him Lucifer, from his former elevation and ſtate of glory: but others explain this paſſage of Iſaiah in reference to the king of Babylon, who had been precipitated from his throne and glory. The Arabians call Lucifer, Eblis; which ſome think is only a diminutive or corruption of the word Diabolus.

DEVISE, or Device, in heraldry, painting, and ſculpture, any emblem uſed to repreſent a certain family, perſon, action, or quality; with a ſuitable motto, applied in a figurative ſenſe. See Motto.

The eſſence of a device conſiſts in a metaphorical ſimilitude between the things repreſenting and repreſented: thus, a young nobleman, of great courage and ambition, is ſaid to have borne for his deviſe, in a late carouſal at the court of France, a rocket mounted in the air, with this motto in Italian, "*poco duri purche m'inalzi*;" expreſſing, that he preferred a ſhort life, provided he might thereby attain to glory and eminence.

Deviſe, or Diviſe, in common law, the act whereby a teſtator gives, or bequeaths, his lands, or goods, by his laſt will, in writing. Though, in ſtrictneſs, a deviſe of goods is more properly termed a bequeſt. He who makes the deviſe, is called the deviſor; and he to whom it is made, the deviſee.

DEVOLVED, ſomething acquired by right of devolution. Such a right is devolved to the crown: ſuch an eſtate devolved on M—— by the death of N——. If a patron neglects to preſent a benefice in ſix months, the preſentation lapſes, or devolves upon the biſhop, from thence to the primate, and from thence to the king.

DEVOLUTION, in law, a right acquired by deſcent, or ſucceſſion, from degree to degree.

DEVOTION, of *devoto*, from *devoveo*, *I conſecrate*, a ſincere, ardent worſhip of God. Monſ. Jurieu defines devotion, a ſoftening and yielding heart, with an inward conſolation, which good men feel in the exerciſes of piety. Under the name of devotions are uſually underſtood certain religious practices, which a perſon makes it a rule to diſcharge regularly; and with reaſon, if this exactitude be founded on ſolid piety; otherwiſe it is vanity, or ſuperſtition.

DEVOURING, in heraldry. When fiſhes are borne in an eſcutcheon, in a feeding poſture, the heralds denominate it devouring; becauſe fiſhes ſwallow all their food whole.

DEUTEROCANONICAL, an appellation given to certain books of the Holy Scripture, which were added to the canon after the reſt; either becauſe they were not wrote till after the compilation of the canon, or becauſe of ſame diſputes as to their canonical authority. The word is Greek, being compounded of δευτερος, *ſecond*, and κανονικος, *canonical*. The Jews, it is certain, acknowledge ſeveral books in their canon, which were put there later than the reſt. They ſay, that, under Ezra, a great aſſembly of their doctors, which they call, by way of eminence, the great ſynagogue, made the collection of the ſacred books, which we have now in the Hebrew Old Teſtament: and they agree, that they put books therein which had not been ſo before the Babyloniſh captivity. Such are thoſe of Daniel, Ezekiel, Haggai, &c. and thoſe of Ezra and Nehemiah. And the Romiſh church has ſince added others to the canon, that were not, nor could be, in the canon of the Jews; becauſe ſome of them were not compoſed till after the canon was formed. Such is the book of Eccleſiaſticus; with ſeveral of the apocryphal books, as that of the Maccabees, Wiſdom, &c. Others were added ſtill later, becauſe their canonical authority had not been yet examined; and, till ſuch examen, and judgment, they might be ſet aſide, at pleaſure. But ſince that church has pronounced as to the canonical authority of theſe books, there is no more room now for her members to doubt of them than there was for the Jews to doubt of thoſe of the canon of Ezra: and the deuterocanonical books are, with them as canonical as the protocanonical; the only difference between them conſiſting in this, that the canonical authority of the one was not generally known, examined, and ſettled, ſo ſoon as that of the others.

The deuterocanonical books, in the modern canon, are, the book of Eſther, either the whole, or at leaſt the ſeven laſt chapters of it; the Epiſtle to the Hebrews; that of James; and that of Jude; the ſecond of St. Peter; the ſecond and third of St. John; and the Revelation. The deuterocanonical parts of books are, the Hymn of the Three Children; the Prayer of Azariah; the hiſtories of Suſanna, of Bel and the Dragon; the laſt chapter of St. Mark; the Bloody Sweat, and the appearance of the Angel, related in St. Luke, chap. xxii. and the hiſtory of the Adulterous Woman in St. John, chap. viii.

DEUTERONOMY, one of the ſacred books of the Old Teſtament; being the fifth book of the law, and the laſt of thoſe written by Moſes; cloſing according to the computation of Archbiſhop Uſher, the hiſtory of 2552½ years, from the beginning of the world to the death of Moſes. The word is Greek, compounded of δευτερος, *ſecond*, and νομος, *law*.

It does not appear that Moſes made any diviſion of what he wrote, into books; or that he gave different names and titles to the different parts of his work; nor do the Jews, even at this day, diſtinguiſh them in the copies they uſe in the ſynagogues, but write them all running as one ſingle work, without any other diſtinction beſide that of little and great paraſches. It is true, in the other copies, uſed by private perſons, they are divided into five parts, as among us; but they give them no other name but the firſt word wherewith each diviſion begins; much as we do in quoting a decree, or chapter of the canon law.

The book of Deuteronomy was written in the fortieth year after the delivery from Egypt, in the country of the Moabites beyond Jordan; Moſes being then in the 120th year of his age. It contains, in Hebrew, eleven paraſches, though only ten in the editions of the rabbins at Venice; twenty chapters, and 955 verſes. In the Greek, Latin, and other verſions, it contains thirty-four chapters: the laſt was not written by Moſes. Some ſay it was added by Joſhua, immediately after Moſes's death; others will have it added by Ezra, which is the moſt probable opinion; who likewiſe made ſome interpolations in the book itſelf, as chap. ii. ver. 12. chap. iii. 11. and 14.

DEUTEROSIS, the Greek name by which the Jews called their *miſchna*, or ſecond law. *Deuteroſis* in Greek has the ſame ſignification almoſt as *miſchna* in Hebrew; both ſignify an iteration. Euſebius accuſes the Jews with corrupting the true ſenſe of Scripture with the trifling explanations of their *deuteroſis*. Calmet, Dict. Bibl. in voc.

DEW, *Ros*, a thin, light, inſenſible miſt, or rain, aſcending with a ſlow motion, and falling while the ſun is below the horizon. Caſaubon derives the word from the Greek δευω, *I moiſten*. Naturaliſts uſually rank dew among the number of meteors of the watery kind. Some define it a vapour liquefied, and let fall in drops; others, a vapour having a like relation to froſt as rain has to ſnow, &c. Among the diſſertations of Monſ. Huet, is a letter to ſhew that dews do not fall, but riſes. M. Gerſten likewiſe adopted the ſame opinion. To us, dew appears only to differ from rain as more and leſs. Its origin, and matter, no doubt, is from the vapours and exhalations of the earth and water raiſed, as ſhewn under the article Evaporation, where the theory of its aſcent and precipitation is particularly explained. M. du Fay made ſeveral experiments, firſt with glaſſes, and then with pieces of cloth, faſtened to two ladders, joined at top, and ſpreading wide at bottom, and reaching about thirty-two feet high, in order to evince the aſcent of dew; and he found that the lower bodies, with their under ſurfaces, were wetted before thoſe that were placed higher, or their upper ſurfaces.

From the principles propoſed and illuſtrated, under the article Evaporation the ſeveral phenomena of dews are eaſily accounted for. Hence, e. gr. it is that dews are more copious in the ſpring than in any other ſeaſons; there being then a greater ſtock of vapour in readineſs, through the ſmall expence thereof in the winter's cold and froſt, than at other times. Hence, what Pliny relates of Egypt, that it abounds in dews throughout all the heats of ſummer; for the air there being too hot to conſtipate the vapours in the day time, they never gather into clouds, and hence they have no rain: but we know, that in climates where the days are exceſſive hot, the nights are remarkably cold; ſo that the vapours raiſed after ſun-ſet are readily condenſed into dews. The quantity and quality of the aſcending dew in particular places depend on a variety of circumſtances, as the ſituation, the nature of the ſoil, the ſtate of the air, and the ſeaſon of the year.

The dew of plants is probably only the moiſture that continually exhales through the orifices of their veſſels, aud not a vapour collected by their leaves: for this dew is expired by each plant, according to the peculiar ſtructure of its veſſels, and the ſituation of their orifices. Plants likewiſe that have been ſhut up in veſſels, and covered by glaſſes, have collected a greater quantity of dew in the night than thoſe that ſtood in the open air; and farther the drops are gathered in thoſe parts, where the orifices of the veſſels are manifeſtly open, and not all over the leaves, and not in the upper or lower leaves only, which would be the caſe if they aroſe from ambient vapour, but in all the leaves, without diſtinction. The oily or honey dew, which is ſometimes exhaled in ſummer by trees and herbs, and which has been found to ſettle on the oak, aſh, &c. is of this kind. Muſchenbroeck Introd. ad Philoſ. Nat. vol. ii. p. 987. 995. ed. 1772.

May Dew. The dew that falls in the beginning of ſummer, particularly in this month, has great virtues attributed to it by many authors, when newly gathered and clean filtered. It is not of a watery appearance, or colourleſs, but is yellowiſh, and much reſembles the urine of a healthful perſon. It is uſed for whitening linen and wax.

We have in the Philoſophical Tranſactions, very odd accounts of productions of the animal kingdom, in the ſame dew; which might puzzle any one not verſed in experiments of this kind with other fluids. In one of the veſſels of this dew were found millepedes, differing from the common kind in ſome particulars; theſe were the common water millepedes: and in another, a quantity of green matter, probably a conferva, with numerous eulæ of inſects inhabiting it; for in a few days there were produced from this a vaſt number of flies. Another quantity of the dew, ſet in an open glaſs, was found after ſome days filled with the eulæ of the common gnat, and the flies were hatched from theſe. Phil. Tranſ. N° 3. It is eaſy for a bad philoſopher to infer from theſe accounts the equivocal generation of theſe creatures in the water; but the inſight we have had into the wonders of nature in the inſect-world are ſuch, that at preſent we know their generation to be in many ſpecies, particularly in the gnats and fly kind, from the eggs of their parents depoſited in water, or any watery fluids, and that common ditch water will at any time do what the dew does in this experiment.

Dew *Born*, in the management of cattle, an exceſſive ſwelling of the body, proceeding from the greedineſs of a beaſt, to feed, when put into rank paſture.

This ſwelling is often ſo great that the creature runs the utmoſt hazard of burſting; in which caſe it ſhould be made to ſtir much, and purge well; but the proper cure is to bleed the creature in the tail, then putting a nutmeg into an egg, to thruſt it down the creature's throat, ſhell and all; after which, by walking him up and down, he will ſoon recover.

DEXTER, in heraldry, is applied to the right ſide, as ſiniſter is to the left.

DEY, the title of the ſovereign of Algiers, under the protection of the grand ſeignior. A prince under this title was appointed by the ſultan, at the requeſt of the Turkiſh ſoldiers, in the year 1710. The term *dey*, in the Turkiſh language, ſignifies *an uncle* by the mother's ſide; and the reaſon of the denomination is this; that the Turkiſh military conſider the grand ſeignior as their father, the republic as their mother, by which they are nouriſhed and maintained, and the *dey* as the brother of the republic, and conſequently the uncle of all who are under his dominion. Beſides the age, experience, and valour, which are neceſſary qualifications of a perſon to be elected, he muſt alſo be a native Turk, and have made the voyage to Mecca. He has no guards, nor conſiderable retinue; he preſides at the divan, and is moſt diſtinguiſhed by the reſpect and ſubmiſſion which are paid him.

DIA, Δια, the beginning of divers terms in medicine, ſurgery, pharmacy, &c. Where theſe three letters commence the name of a remedy, unguent, plaſter, cataplaſm, &c. they ſignify compoſition and mixture; as in *diapaſma*, *diachylon*, &c.

Dia is likewiſe the beginning of many terms in the other arts: as diameter, dialogue, &c. on all which occaſions, *dia*, which is an inſeparable particle, or prepoſition, is borrowed from the Greek δια, *ex*, or *cum*; which begins the ſame words in the Greek. Indeed we have words wherein *dia* is no prepoſition borrowed from a foreign language; though it is poſſible, the words themſelves may; as in *diamond*, *dial*, &c.

DIABETES, Διαβητης, in medicine, a haſty and profuſe evacuation of the drink by the urinary paſſages; accompanied with an ardent thirſt, and leanneſs of the whole body. The word is derived from the Greek διαβαινειν, to *pervade*, or *paſs quick*.

The drink, thus diſcharged, is uſually a little altered from what it was when taken down, and turned chylous, and milky; but ſometimes not at all. The diabetes ſeems owing to a too great laxity of the fibres, of the arteries of the kidneys; or too great a quantity of ſharp ſalts in the blood, which diſſolve the maſs of blood, or diſunite the parts thereof, ſo that the ſeroſity is early ſeparated from the thicker parts. According to Quincy, the evident and moſt common cauſe of the diabetes is the too great uſe of ſpirituous liquors, wherewith the ſerum becomes ſo impregnated, that it will not attact and join with the cruor, or globules of the blood, but runs off through the kidneys, ſweet or inſipid.

It happens moſt frequently to thoſe who, without due exerciſe, indulge themſelves with drinking vinous liquors, and then quench their thirſt ariſing from thence by too great a quantity of ſuch as are cooling. In this diſeaſe the urine is thin and pellucid, and has no ſediment, and is of a ſweetiſh taſte; though caſes have occured, in which it has not had this taſte; the quantity voided is always very great; and if the patients endeavour to retain it, they are afflicted with ſwellings about the loins, and a ſenſation of weight and preſſure in the hypochondria. It is attended with thirſt, a hectic heat, a weak but quick pulſe, and gradual waſting of the fleſh.

According to Dr. Mead, the diabetes is a diſeaſe of the liver, and not of the ſecretory veſſels of the kidneys, as has been generally thought. See Monit. and Pract. Medic. cap. ix. ſect. 2. and Mechanic Account of Poiſons, Eſſay. 1. ed. 4.

The doctor recommends the following medicine as efficacious in this diſtemper: take four pints of milk, boil it a little, and turn it with three drams of alum; four ounces of this ſhould be taken three times a day at leaſt. Dr. Brockleſby attributes great efficacy, in a caſe where he was concerned, to alum whey, made by boiling from fifty to thirty grains of powdered roche-alum, in a ſufficient quantity of new milk from the cow, to afford a full pint of whey; half of which was drank by the patient every night and morning, for ſix weeks. Med. Obſ. vol. iii. p. 279.

Dr. Dobſon, of Liverpool, made ſeveral experiments, in order to aſcertain the nature of this diſeaſe; and he conſiders it as a ſpecies of imperfect digeſtion or aſſimilation, and to be more of a diſeaſe of the ſyſtem in general than either of the liver or kidneys. On this ſyſtem he accounts for the different taſte of the urine in different ſubjects, the emaciating effects of this diſeaſe, the acid ſweats, and the ſenſation of hunger that attend it. From hence he infers, that the obvious indications of cure, are to ſtrengthen the digeſtive powers, to promote a due ſanguification, and to eſtabliſh a perfect aſſimilation through the whole œconomy. Med. Obſ. vol. v. art. 27.

Diabetes, in hydraulics, is applied to a ſyphon, the two legs or branches whereof are incloſed in one another; as in the glaſs deſcribed by Hero, which runs itſelf quite empty, without being inverted, as ſoon as the water is arrived at the height of the upper branch of the ſyphon.

DIACAUSTIC *Curve*, or cauſtic by refraction, is a ſpecies of cauſtic curves, whoſe geneſis may be thus conceived.

DIACHYLON, in pharmacy, a name given to divers plaſters on account of the mucilages mixed therein, which are viſcid juices, called by Greeks χυλοι, drawn from certain plants.

DIACODIUM, in pharmacy, ſyrup prepared from poppy-heads, called alſo *ſyrupus de meconio*. The word is formed from the Greek δια, *per*, κωδεια, *poppy-heads*. The ancients had two kinds: *ſimple* and *compound*.

DIACOPE, Διακωπη, from δια and κοπτω, *I cut off*, in grammar, the ſame with what is otherwiſe call tmeſis.

DIACOUSTICS, or Diaphonics, the conſideration of the properties of ſound refracted in paſſing throngh different mediums; that is, out of a denſer into a more ſubtle, or out of a more ſubtle into a denſer medium. The word is formed from the Greek δια, *per*, *through*, which imitates a paſſage; and ακεω, *I hear*, q. d. the conſideration of the paſſage of the ſounds we hear.

DIADELPHIA, in the ſexual ſyſtem of botany, being the ſeventeenth claſs of plants with hermaphrodite flowers, whoſe ſtamina, by the conjunction of their filaments, are formed into two bodies, the one ſtanding about the piſtil, and the other ſurrounding it. The word is formed from the Greek δις, *twice*, and αδελφος, *brother*.

This is a perfect natural claſs of plants, and is the moſt remarkable of all others in the ſtructure of the flower. The common ſituation of the flower is an obliquely pendulous direction, or in an acute angle from a perpendicular line. The former ſyſtematiſts in botany, as Linnæus obſerves, took great notice of the pod in this claſs of plants, and thought it the principal ſubject of diſtinction; but he very judiciouſly makes it but of very little conſequence, and will not allow it ſufficient to diſtinguiſh the genera one from another: but the cup, which had always before his time been diſregarded, he eſteems a very eſſential part of the plant, and ſufficiently certain to erect the different genera upon in many caſes. Some of the old writers had been uſed to take the leaves into their marks, by which to diſtinguiſh genera of this claſs; but Linnæus wholly excludes this part of a plant from this office. Magnol has obſerved, that the carina of the diadelphia, or papilionaceous flowers, is dipetalous, and is compoſed of two diſtinct oblong petals; the lower edges of which join ſo nicely and cloſely together, that they ſeem only one; and are not joined in their ſubſtance, but only in their ſituation. Linnæus has ſtrictly examined this, and finds that the author is ſo far right, that this is really the caſe in many of the papilionaceous flowers, but not in all: ſome not only appearing to have, but really and certainly having a carina compoſed of only one petal.

The conſideration of the ſtigma is of more conſequence in this than in moſt other flowers, and even more than that of any other part of the fructification in this. The ſeeds of all the plants of this claſs are eatable, excepting in a very few particulars: their leaves alſo are a grateful food to cattle. Lin. Gen. Plant. p. 377. Of this claſs there are four orders, viz. the pentandria, comprehending one genus; the hexandria, two; the octandria, two: and the decandria, forty-nine. See Syſtem of Botany, Sect. V. Claſs 17, and Plate V.

DIADEM, in antiquity, a head-band, or fillet, worn by kings as a badge of their royalty. It was made of ſilk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck. It was uſually white, and quite plain; though ſometimes embroidered with gold, and ſet with pearls and precious ſtones. In latter times, it came to be twiſted round crowns, laurels, &c. and even appears to have been worn on divers parts of the body. The word comes from the Latin *diadema*; of the Greek διαδημα, *a little band encompaſſing the head*, of the verb διαδεω, *cingo*, "I gird."

Diadem, in heraldry, is applied to certain circles or rims, ſerving to bind or encloſe the crowns of ſovereign princes; and to bear the globe, and croſs, or the fluers-de-lys, for their creſt. The crowns of ſovereigns differ in this, that ſome are bound with a greater, and ſome with a leſs, number of diadems. In blazoning, the bandage about the heads of Moors, on ſhields, is ſometimes alſo called *diadem*.

DIÆRESIS, in ſurgery, the operation of dividing and ſeparating parts, whoſe union and continuity were an obſtacle to the cure; or which were joined and conglutinated contrary to the order of nature. The word, in its original Greek, διαιρεσις, ſignifies *diviſion*.

Diæresis is uſed, in medicine, for deſtroying or conſuming of the veſſels, or canals, of an animal body; when, from ſome cutting, or corroding humour, certain paſſages are made, which naturally ought not to have been; or certain natural paſſages are dilated beyond their ordinary dimenſions; ſo that the juices, which ſhould have been contained therein, extravaſate, or run out.

Diæresis, in grammar, is a figure whereby a diphthong is divided into two ſyllables: as *aulæ* into *aulai*, *pictæ* into *pictai*, *aquæ* into *aquai*.

Diæresis is alſo uſed in a general ſenſe, for any diviſion of one ſyllable into two: as in that verſe of Tibullus, *Stamina non ulli diſſoliinda deo*, for *diſſolvenda*. This is uſually noted by two points placed over a letter, to ſhew that it is to be ſounded by itſelf, and not joined with any other ſo as to make it a diphthong: thus *aëra*, by the points over the *e*, is diſtinguiſhed from *æra*. It is alſo a kind of metaplaſm, or addition to a word, by dividing one ſyllable into two: as *aulae*, by a *diaræſis*, is a word of three ſyllables, inſtead of *aulæ*.

DIAGNOSTIC, in medicine, a term applied to thoſe ſigns or ſymptoms, which indicate, or diſcover, the preſent ſtate of a diſeaſe, its nature and cauſe. The word is compounded of the Greek δια, *per*, *through*, or *by*; and γινωσκω, *I know*. The phyſicians have *diagnoſtic* as well as *prognoſtic* ſigns; the firſt, with regard to the preſent ſtate of the diſeaſe, and the patient; and the ſecond to the future.

DIAGONAL, in geometry, a right line drawn acroſs a parallelogram, or other quadrilateral figure, from the vertex of one angle to that of another. See Syſtem of Geometry.

DIAGRAM, from διαγραφω, *I deſcribe*, in geometry, &c. a ſcheme for the explanation, or demonſtration, of any figure, or the properties thereto belonging. See Syſtem of Geometry.

Diagram, or Diagramma, in the ancient muſic, was what we call the ſcale, or gammut, in the modern. See Syſtem of Music.

DIAH, or Diat, a name given by the Arabs to the puniſhment of retaliation. By the Mahometan law, a brother, or the next relation of a murdered perſon, ought to take part againſt the murderer, and demand his blood in reparation for that which he has ſhed. Before the time of Mahomet, the Arabs had a cuſtom of putting a freeman of their priſoners to death, in lieu of every ſlave they loſt in battle, and a man for every woman that was killed. But Mahomet regulated the laws of repriſal; directing in the Alcoran, by the diat, that a freeman ſhould be required for a freeman, and a ſlave for a ſlave. The Turks, probably in conſequence of this law, formerly maſſacred almoſt all their priſoners of war, but they now content themſelves with enſlaving and ſelling them. French Encyclopædia.

DIAL, or *Sun* Dial, an inſtrument ſerving to meaſure time by means of the ſhadow of the ſun. The word is formed from *dies*, *day*, becauſe indicating the hour of the day. The ancients alſo call it *ſciathericum*, from its doing it by the ſhadow. See Treatiſe on Dialling.

DIALECT, Διαλεκτος, from διαλεγεσθαι, *to diſcourſe*, the peculiar language of ſome province, or part, of a nation, formed by corruption of the general, or national language.

Homer could ſpeak five different languages in one verſe, i. e. five *dialects*; viz. the Attic, Ionic, Æolic, the Doric, and the common *dialect* of the Greeks.

The Attic *dialect* is more particularly uſed by Xenophon and Thucydides; the Ionic by Herodotus and Hippocrates; the Doric by Pindar and Theocritus; the Æolic by Sappho and Alcea, and often by the two former writers. The Bologneſe, Bergamaſque, Tuſcan, &c. are the *dialects* of the Italian; the Gaſcon, and Picard, are *dialects* of the French. In Great Britain, almoſt every county has a *dialect* of its own, all differing conſiderably in pronunciation, accent, and tone, though the language be the ſame. The method which the Gileadites took to prove the Ephraimites, by the pronunciation of *ſhibboleth*, with *ſchin*, or *ſamech*, is well known. Judges xii. 6.

The following Treatiſe of Dialling *is the Production of Mr.* Robert Moody, *of the* Exciſe, Broad Street, *and Author of the Syſtem of* Algebra *in this Work.*

A TREA-

A TREATISE ON DIALLING.

PART I. SECT. I.

DIALLING is the Art of drawing Dials on any given plane, or on the ſurface of any given body.

The Greeks and Latins named this art *gnomonica*, and *ſciatherica*, becauſe through it they were taught to diſcover the hour of the day by the ſhadow of a gnomon. Some have named it *photoſciatherica*, for this reaſon, that the hours are commonly exhibited by the *light*, or rather the *ſhade*, of the ſun. Others have called the art *horologiography*; and others again *ſciographia*, becauſe it treats of ſhadows.

It is uncertain, who was the firſt that found out the art of conſtructing dials. Some attribute the invention to Anaximenes Mileſius, who lived about 556 years before Chriſt; others, to Thales, who flouriſhed about the ſame time, or rather earlier. But to leave the opinions of different authors, I think it is evident, that the art of making dials was known long before the days of either of theſe philoſophers. Witneſs, the dial of Ahaz, mentioned in Iſaiah, chap. xxxviii. ver. 8. which muſt have been at leaſt 150 years prior to the date abovementioned. It appears, however, that the Romans were unacquainted with dials till Papirus Curſor, about 260 years before the Chriſtian æra ſet up a dial at Rome, prior to which, ſays Pliny, there is no mention of any account of time, other than by the ſun's riſing and ſetting.

Clavius is ſaid to be the firſt profeſſed writer on this ſubject. The art has been ſince handled by Dechales, Ozanam, Wolfius, M. Picard, De la Hire, Sturmius, Paterſon, Michael, Leybourn, Leadbetter, Muller, Ferguſon, and many others. But among all the books on dialling, none are more deſervedly eſteemed than that of J. Wells, Eſq. printed at London in 1635, under the title of "The Art of Shadows," and that excellent Treatiſe of the late Mr. Emerſon, printed in 1770.

There are various methods of drawing dials. Some find all the requiſites by means of a terreſtrial globe, and then transfer them to the dial plane, but in the conſtruction of large dials, where accuracy is required, this method is too vague and uncertain. Others find the requiſites by trigonometrical calculations, and inſert them in a table for uſe, and ſo taking off the due meaſure of each from a plain ſcale of proper ſize, they eaſily and accurately form the ſeveral lines on the dial plate.

Others, again, conſtruct from a *dial ſcale* fitted to the particular latitude of the place; but, as in the practice of making dials a variety of latitudes will occur, and it would be exceeding difficult, nay, almoſt an endleſs taſk, to procure ſuch ſcales for all latitudes; or if procured, as the advantage would never compenſate for the expence, this method is not fit for general uſe, and of courſe is not worth notice in this place, as the œconomy of our plan is cautiouſly to avoid extranuous matter and things of ſmall importance, while we wiſh to be copious, and to afford our readers every ſatisfaction in thoſe articles which appear to be of real utility.

Another method of conſtructing dials is by lines drawn purely geometrical, without the help of calculation, and this method being more mechanical and ſcientific than the reſt, would be the beſt for practice; was it not that in ſome caſes the lines become ſo numerous, and their interſections ſo many, as to render it both tedious and inaccurate.

In what follows, I ſhall therefore prefer that method by the ſcale with the help of calculation, it being the moſt general, correct, and expeditious; not, however, omitting the geometrical method, in caſes where it is well adapted for actual uſe.

Before I enter into the practice of deſcribing dials, it will be neceſſary to treat of the gnomonic projection of the ſphere.

SECT. II.

GNOMONIC PROJECTION OF THE SPHERE.

IN the gnomonic projection, the plane projected on, is ſuppoſed to touch the hemiſphere to be projected, in its vertex; the point of contact being the centre of projection. But a projection may be made nothing differing from this, upon any plane parallel to ſuch touching plane; for it is only taking a greater or leſs radius of projection, according to the greater or leſs diſtance, which is in effect projecting a greater or leſs ſphere upon its touching plane.

When the ſphere is to be projected this way upon a given plane, it will aſſiſt the imagination to ſuppoſe the eye placed in the centre of the ſphere and looking on the plane whoſe poſition is given; as by that means, the circles of the ſphere, as projected on the plane, will appear in due order.

In this projection, every great circle as BAD (*Fig.* 1.) is projected into a right line, perpendicular to the line of meaſures, and at a diſtance from the centre equal to the cotangent of its inclination, or the tangent of its neareſt diſtance from the pole of projection.

For let CBED be perpendicular both to the given circle BAD and the plane of projection, then will the interſection CF be the line of meaſures. Now ſince the plane of the circle BD and the plane of projection are both perpendicular to BCDE, the common ſection will alſo be perpendicular to BCDE, and conſequently it will alſo be perpendicular to the line of meaſures CF. Now ſince the projecting point A is in the plane of the circle, all the points of the circle will be projected into that ſection; that is, into a right line paſſing through d, and perpendicular to Cd. And Cd is the tangent of CD, or cotangent of CdA.

Hence a great circle perpendicular to the plane of projection, is projected into a right line; paſſing through the centre of projection, and any arch is projected into its correſpondent tangent. Thus the arch CD is projected into the tangent Cd.

Alſo any point as D, or the pole of any circle, is projected into a point d diſtant from the pole of projection C, the tangent of D's diſtance from the ſaid pole.

If two great circles be perpendicular to each other, and one of them paſſes through the pole of projection, they will be projected into two right lines perpendicular to each other.

Therefore, if a great circle be perpendicular to ſeveral other great circles, and its repreſentation paſs through the centre of projection, then all theſe circles will be repreſented by lines parallel to one another, and perpendicular to the line of meaſure or that firſt circle.

If two great circles interſect in the pole of projection, their repreſentations ſhall make an angle at the centre of the plane of projection, equal to the angle made by thoſe circles on the ſphere.

Any leſs circle parallel to the plane of projection, is projected into a circle, whoſe centre is the pole of projection; and radius, the tangent of the circle's diſtance from the pole of projection. Hence, if a circle be parallel to the plane of projection, and 45° from the pole, it is projected into a circle equal to a great circle of the ſphere, and therefore it may be looked upon as the primitive circle in this projection, and its radius eſteemed, the radius of projection.

Every leſs circle (not parallel to the plane of projection) is projected into a conic ſection, whoſe tranſverſe axis, is the line of meaſures, and whoſe neareſt vertex is at a diſtance from the centre of the plane, equal to the tangent of its neareſt diſtance from the pole of projection; the other centre is diſtant therefrom equal to the tangent of its fartheſt diſtance from the pole of projection.

For let BE (*Fig.* 2.) be parallel to the line of meaſures dp, ſo will any circle be the baſe of a cone whoſe vertex is A, and therefore ſuch cone being produced will be cut by the plane of projection in ſome conic ſection. Thus the circle whoſe diameter is DF, will be cut by the plane in an ellipſis, whoſe tranſverſe axis is df; and Cd is the tangent of CAD, and Cf of CF. In like manner, the cone AFE being cut by the plane f, will be the neareſt vertex, and the other point in which E is projected is at an infinite diſtance. Alſo the cone AFG (whoſe baſe is the circle FG) being cut by the plane f, is the neareſt vertex, and GA, being produced, gives d the other vertex.

It follows from what has been ſaid, that if the diſtance of the fartheſt point of the circle be leſs than 90° from the pole of projection, it will be projected into an ellipſis.

If the fartheſt point be more than 90° from the pole of projection, it will be projected into an hyperbola. Thus the circle FG is projected into an hyperbola, whoſe vertices are f and d, and tranſverſe fd.

In the circle EF, where the fartheſt point E is juſt 90° from C, it will be projected into a parabola, whoſe vertex is f.

Alſo if H be the centre, and K, k, l, the focus of the ellipſis, hyperbola, or parabola, then $HK = \frac{Ad - Af}{2}$, for the ellipſis; $Hk = \frac{Ad + Af}{2}$ for the hyperbola; and (drawing fn perpendicular to AE) $fl = \frac{nE + Ff}{2}$, for the parabola, which are the repreſentations of the circles DF, FG, and FE reſpectively.

Theſe things being premiſed, I proceed to the practical part of projection, in which, for the ſake of brevity and utility, I ſhall confine myſelf as much as poſſible to the method by the plain ſcale, the other methods which depend upon rigid geometrical conſtructions, being in ſome caſes exceeding tedious, and on account of the variety of lines and interſections that occur, the figures when conſtructed are liable to far greater inaccuracy than when they are drawn at once from a correct ſcale of chords, ſines, tangents, &c.

Art. I. *To draw a great Circle, through a given Point, and at a given Diſtance from the Pole of Projection.* (*Fig.* 3.)

Rule. With the radius of projection deſcribe the circle ABD, and with the tangent of the circle's diſtance from the pole of projection C, deſcribe the circle EIF, and draw PK to touch this circle, ſo will PIK be the circle required.

Art. II. *To draw a great Circle perpendicular to a given Circle, that paſſes through the Pole of Projection, and at a given Diſtance from that Pole.* (*Fig.* 3.)

Rule. The primitive circle ABD being drawn in the given circle CI, ſet the tangent of the given diſtance from C to I; through I draw Kp perpendicular to CI, and it will be the repreſentation required.

Art. III. *To meaſure any Part of a great Circle or to ſet any Number of Degrees thereon.* (*Fig.* 4.)

Rule. Let EP be the great circle, EBD be a circle deſcribed with the radius of projection, and let IP be a part of the great circle; draw HD perpendicular to EP; apply CI to the tangents, and ſet the ſemitangent of its complement from C to A, which will be the dividing centre of EP; and drawing AP, the angle IAP will conſequently be the meaſure of the given arch IP.

If the degrees be given, make the angle IAP equal thereto, which, (by drawing AP to meet the circle EP,) will cut off IP, the arch correſpondent thereto.

Art. IV. *To draw a great Circle ſo as to make a given Angle with a given great Circle, at any aſſigned Point; or to meaſure an Angle made by two great Circles.* (*Fig.* 5.)

Rule. Let P be the given point, and PB the given great circle. Draw through P, and C, the centre of projection, the line PCG; to which from C, draw CA perpendicular, and equal to the radius of projection. Draw PA and AG perpendicular to it; at G, erect BD perpendicular to GC, cutting PB in B; draw AO biſecting the angle CAP. Then at the point O make BOD equal the given angle, and from D draw the line DP; ſo will BPD be the angle required. Or, if the degrees in the angle BPD be required; from the points BD, draw the lines BO, and DO, and the angle BOD will be the meaſure of BPD.

Cor. If an angle be required to be made at the pole or centre of projection, equal to a given angle, this will be effected by drawing two lines from the centre, making the angle required.

Also, If one great circle is to be drawn perpendicular to another great circle, it muſt be drawn through its pole.

Art. V. *To project a leſs Circle parallel to the Primitive.*

Rule. With the radius of projection AC (*Fig.* 3.) and centre C, deſcribe the primitive circle ADB, and with the radius CE, equal to the tangent of the circle's diſtance from its pole, deſcribe the circle EFG for the circle required.

Art. VI. *To draw a leſs Circle perpendicular to the Plane of Projection.* (*Fig.* 6.)

Rule. Through the centre of projection C, draw its parallel great circle TI; take the tangent of the circle's diſtance from its parallel great circle, and ſet it from C (the centre of projection) to V, and the ſecant thereof from C to F. Then with the ſemi-tranſverſe CV, and focus F, deſcribe the hyperbola WVHK, which will repreſent the given circle.

Art. VII. *To project any leſs oblique Circle given.* (*Fig.* 7.)

Rule. Having drawn the line of meaſures *dp*, take the tangents of the circles neareſt and fartheſt diſtance from the pole of projection, and ſet from C to *f* and *d*, which will give the vertices, and biſect *df* in H. Take half the difference or half the ſum of the ſecants of the greateſt and leaſt diſtances from the pole of projection, and ſet from H to K or *k*, for the focus of the ellipſis or hyperbola, which may then be deſcribed; and it will repreſent the given circle.

Art. VIII. *To find the Pole of any Circle in the Projection, DMF.* (*Fig.* 8.)

Rule. From the centre of projection C draw the radius of projection C A perpendicular to the line of meaſures D F; apply D C and C F to the tangents, and ſet the tangent of *half the difference* of their degrees from C to P; if D and F lie on contrary ſides of C; but, *half the ſum*, if on the ſame ſide, and it will give P, the pole; or by Art. III. ſet off from D to P, the circle's diſtance from the pole, which will give P as before.

Cor. If it be a great circle as B G (*Fig.* 9.) draw the line of meaſures G C and C A perpendicular to it, and equal to the radius of projection; make G A P a right angle, ſo will P be the pole required.

Art. IX. *To meaſure any Arch of a leſs Circle; or to ſet any Number of Degrees thereon.* (*Fig.* 9.)

Rule, Let C be the centre of projection, F *n* the arch, and P the pole of the given circle: apply C P to the tangents, and ſet the tangent of its half from C to O, and the cotangent of its half from C to D; with the radius G C taken equal to the tangent of the degrees in F P, (the given circle's diſtance from its pole) deſcribe the circle GSH: then D*l* being drawn through *n* or *l* will cut off H*l* = F *n*. Or, O being found as before, erect O S perpendicular to C O; then through the given point *n* draw P Q *n*, and the angle Q C H will be equal F *n*: Or, apply C P to the tangents, and ſet the cotangent thereof from C to G. Erect G B perpendicular to G C. Through *n* draw P *n* B; and join B O, ſo will the angle G O B = F *n*.

Cor. If the leſs circle be perpendicular to the plane of projection as V K K (*Fig.* 6.) it is only drawing the perpendiculars V C, H G, to its parallel great circle C I; and C G (meaſured by Art. III.) will be equal to V H; or the degrees ſet from C to G, will cut off V H equal thereto.

An **Example** illuſtrating the foregoing **Rules.**

Let it be required to project the Sphere on a Plane parallel to the Horizon, for July 31, 1787, *at* 10 *in the Morning. Lat.* 35½ *N.* (*Fig.* 10.)

With the radius of projection and centre C deſcribe the primitive circle A D B. Through C draw the meridian P E, and A S perpendicular to it for the prime vertical. Set off C P = 35½, the latitude, ſo will P be the north pole. Draw P *p* perpendicular to C P, for the 6 o'clock meridian. Set the co-latitude from C to E, and draw E Q perpendicular to C E for the equinoctial. Make E B = 30° (or two hours the time from noon) and draw the 10 o'clock meridian P B. Set the ſun's declination 18° 27′ from B to ⊙, then will ⊙ be the ſun's place at 10 o'clock. Through ⊙ draw the azimuth circle C Q. Alſo through ⊙ may be drawn (by Art. VII.) a parallel to the equinoctial E Q for the ſun's parallel of declination.

C O meaſured by Art. III. = 31° ½, the complement of the ⊙'s altitude; and the angle E C ⊙ meaſured by Art. IV. = 65°, 10′, his azimuth.

In like manner may be drawn any other circles of the ſphere, and the places of moon, ſtars, and planets exhibited.

PART II. SECT. III.

THE PRACTICE OF DRAWING VARIOUS SORTS OF DIALS.

This I ſhall endeavour to methodize, by reducing the different kinds to three claſſes, for all dial planes are either parallel, perpendicular, or inclining to the horizon.

Definitions.

1ſt. *Dial Planes*, are thoſe on which dials are or may be deſcribed.

2d. *The Denomination of any Dial*, is taken from that great circle of the ſphere, to which the dial plane is parallel.

3d. *Declination of a Plane*, is an arch of the horizon, contained between the plane and the prime vertical, or between the meridian and a plane perpendicular to the dial plane, and is always reckoned from the South or North.

4th. *Reclination of a Plane*, is the angle which it makes with a vertical plane.

5th. *Inclination of a Plane*, is the angle which it makes with the horizon.

6th. *The Centre of a Dial*, is the point where all the hour lines meet, or to which they tend.

7th. *The Style or Gnomon of a Dial*, is a pin, or piece of metal or wood, &c. raiſed perpendicular to the plane of the dial, the ſhadow of which, as an index, points out the hour of the day.

8th. *The Subtile*, is the line on which the ſtile is erected. This always paſſes through the centre of the dial.

9th. *The Stiles Height*, is the angle which the upper edge thereof makes with the ſubſtile; but this is to be underſtood when the ſtile is in the form of a triangle, and then the angular point is at the centre of the dial. If the ſtile is a pin, the length thereof is the height. If the ſtile is a parallelogram, the centre is at an infinite diſtance.

10th. *The Subſtiles Diſtance from the Meridian*, is the angle which it makes with the 12 o'clock line.

11th. *Meridian of the Plane*, is the meridian perpendicular to the plane of the dial; it is the ſame as the ſubſtile; but the meridian of the place is perpendicular to the horizon.

12th. *The Height of the Meridian*, is an arch of the great circle, or dial plane, comprehended between the horizon and meridian of the place.

13th. *Plane's Difference of the Longitude*, is the angle on the ſphere, contained between the meridian of the place, and the meridian of the plane. This is alſo called the *Inclination of Meridians*.

14th. *Hour Arch*, is an arch of the Equinoctial anſwering to the time, or the angle at the Pole, thus 15° = 1 hour, 30° = 2 hours, 45° = 3 hours, &c. This takes its beginning at the ſubſtile.

15th. *Hour Angle*, is the angle which any hour line makes with the ſubſtile.

16th. *Horizontal Line*, in any dial, is a line drawn parallel to the plane of the horizon, and is made by the horizontal plane's cutting the dial-plane, and paſſing through that point of the ſtile, whoſe ſhadow ſhews the hours.

17th. *The Equinoctial Line*, is made by the interſection of the plane of the Equinoctial and Dial Plane.

18th. *An Azimuth Line*, is the Interſection of an Azimuth with the dial plane; and ſo for other lines of the like kind.

19th. *The Contingent Line*, is a line drawn through the foot of the ſtile perpendicular to the ſubſtile. It ſerves inſtead of the equinoctial for finding the hour points, through which the hour lines are to be drawn. When the contingent does not paſs through the foot of the ſtile it repreſents the equinoctial.

SECT. IV.

PROPOSITIONS.

Mr. Emerſon has demonſtrated the following Propoſitions reſpecting dials.

Proposition I. If a right line be fixed any where upon the earth, parallel to the earth's axis, the ſhadow thereof by the ſun, will move uniformly about it, deſcribing equal angles in equal times.

2d. If a line be elevated above a plane and fixed there, its ſhadow will be the ſame at the ſame moment of time, in whatever part of the earth it is placed, provided it be in a parallel ſituation.

3d. Hence a dial removed from its true ſituation to any other and placed in a ſituation quite parallel, will, when the ſun ſhines, always ſhew what a clock it is at the place it came from.

4th. In every dial that has a ſtile, the edge of it that gives the ſhadow muſt always be parallel to the earth's axis, and point directly to the two poles.

5th. In any dial, the angle of the ſtile's height above the ſubſtile is equal to the height of the pole above the plane of the dial.

Lodge sculp.

BRITISH 18 MR 63 MUSEUM

6th. The interſection of the meridian of the place and the plane of the dial is always the hour line of 12 o'clock; and all the other hour lines are the interſections of the ſeveral meridians or hour circles, with the plane of the dial, all paſſing through the ſtile.

7th. In a dial with a centre, if the hour lines be produced through the centre, ſo as to appear on the other ſide of the plane; and if the ſtile be alſo produced through the plane, there will be a dial formed on the other ſide of the plane, in which the ſame lines produced refer to the ſame hours.

8th. In all upright dials the hour line of 12 is perpendicular to the horizon.

9th. In a direct eaſt or weſt reclining dial the hour line of 12 is parallel to the horizon.

10th. If any erect declining dial be removed along the plane of its great circle, till its difference of longitude be equal to the planes difference of longitude or inclination of meridians, it will become a full ſouth or north erect dial.

11th. A reclining eaſt or weſt dial plane, will be an upright plane under the ſame meridian at 90° diſtance, and in a parallel ſituation.

SECT. V.

DIALS PARALLEL TO THE HORIZON.

Under this deſcription are thoſe dials that are termed horizontal, their planes being always fixed parallel to the horizon, through which, if obſtacles do not intervene, the ſun ſhines upon them on each day of the year from his riſing to his ſetting, whatever may be the latitude of the place, which is not the caſe with any other kind of dials; and therefore this ſort of all others is of the moſt general uſe.

Art. X. *To conſtruct an horizontal Dial for any given Latitude.*

1ſt. Geometrically. Take any Point as P (*Fig.* 11.) for the centre, through P draw the meridian DE; at P make the angle DPR equal to the latitude. Draw a line parallel to DE, at a diſtance equal to the perpendicular height of the ſtile, cutting PR in F, ſo will FC be the height, and C the foot of the ſtile. Draw FG perpendicular to FP. Through G draw the contingent line AGB perpendicular to DE, which in this caſe repreſents the equinoctial.—Let G*g* be the thickneſs of the ſtile, and draw *dge* parallel to DGE. From G take GF, the neareſt diſtance to PR, and ſet from G to D, and from *g* to *d*; and from the centres G and *g* with any radius deſcribe two quadrants, and divide each into ſix equal parts, or hours. Through the points of diviſion draw lines from the centres D and *d*, interſecting AB in the hour points *m*, *m*; *n*, *n*, &c. then from the centres P and *p* draw lines through the points *m*, *n*, &c. and they will be the hour lines, which may be circumſcribed either by a circle, ſquare, or any other figure, at the pleaſure of the artiſt. The 6 o'clock hour line is drawn parallel to AB, and the hours before and after 6 are had by producing the oppoſite hour lines through the centre.—Alſo PFC will be the form of the ſtile which may be longer at pleaſure, by producing FP.—The ſtile muſt be placed perpendicular to the dial plane, one edge thereof being on PG, and the other on *pg*; ſo will the upper edge ſhew the ſhadow.

If no ſpace is allowed for the thickneſs of the ſtile, the lines DP and *dp*, will coincide; D and *d* will be one point, as alſo P and *p*. The two quadrants will fall into one ſemicircle, and the hour lines will all iſſue from one point. But if the dial is thus conſtructed, the ſtile muſt be made either exceeding thin ſo as to occupy no ſenſible ſpace, or the upper edge thereof muſt be made ſharp, and the ſtile ſo fixed, that ſuch edge may be exactly perpendicular to the ſubſtile.

Inſtead of the triangular gnomon PFC, there may be a perpendicular pin, as FC, and then the ſhade of the top F, will ſhew the hour; or the ſtile may be a plate of any form, with a hole in it, at F, perpendicular to C, for the ſun to ſhine through.

If half hours, or quarters, or ſtill ſmaller meaſures of time are to be ſhewn by the dial, then every hour in each quadrant muſt be divided into ſo many equal parts as are the number of ſuch meaſures in an hour; and lines muſt be drawn from the centres D and *d* interſecting AB, and then lines drawn through ſuch interſections from P and *p* as before. To ſave trouble, after the hour lines are drawn on one ſide of the dial, they may be transferred to the other ſide. The hours on the Eaſt ſide muſt be numbered 1, 2, 3, &c. from PD or XII, for the afternoon hours: and thoſe on the Weſt ſide muſt be numbered 11, 10, 9, &c. for the *forenoon* hours.

2d. By calculation of the plain scale.—The Latitude of the place being given, the only requiſites to be found are the hour angles, which are had by the following proportion. As radius : ſine of latitude : : tangent of hour-arch ; tangent of hour angle.

The hour arches are had by allowing 15° for each hour; 7½° for half an hour, 3° 45' for a quarter of an hour, &c. See Definition XIV.

In the latitude of London = 51° 32', the hour angle anſwering to the ſpace of 1 hour = 11° 51'; for two hours = 24° 19'; for 3 hours = 38° 4'; for four hours = 53° 36'; for 5 hours = 71° 6'; and for 6 hours (in all latitudes) 90°.

Theſe being known, take any point P for the centre, and draw PD for the meridian. Take P*p* = to the thickneſs of the ſtile, and draw *p d* parallel to PD. Make the angles DP XI. and *dp* each = 11° 51', for the hour lines of XI. and I; the angles DPX, and *d p* III, each = 24° 9', for the hour lines of X and II. The angles DP IX, and *dp* III = 38° 4', for the hour lines of IX and III, and ſo for the reſt.—Alſo the angles for the half hours, and quarters of hours, muſt be found by the foregoing proportion, and then laid down as above.—If ſmaller diviſions than quarters of hours are required, it will generally be near enough, after the quarters are drawn, to divide them into as many equal parts as you pleaſe, without further trouble of calculation.

Laſtly, make the angle DPR = to the latitude for the ſtile or gnomon.

I have been the more copious in explaining this Dial, that what follows may be the clearer underſtood.

SECT. VI.

DIALS PERPENDICULAR TO THE HORIZON.

Under this deſcription are all dials, whoſe planes are vertical.—Theſe may be diſtinguiſhed into two kinds, viz. *direct*, and *declining*.—A direct dial is one that is drawn on a plane, facing either the Eaſt, Weſt, North, or South; and ſuch a dial is accordingly named, an Eaſt Dial, a Weſt Dial, a North Dial, or a South Dial.

The Eaſt and Weſt Dials are parallel to, or in the plane of the meridian, and the North and South Dials are parallel to or in the plane of the prime vertical.

A Declining Dial is one that faces none of the cardinal points, but declines towards the Eaſt or Weſt.—They come under theſe our denominations, viz. A South-eaſt Decliner, a South-weſt Decliner, a North-eaſt Decliner, and a North-weſt Decliner.

Art. XI. *To conſtruct Dials perpendicular to the Horizon.*

Case I. *To draw a direct Dial, as for Inſtance, an erect direct South Dial.*

1ſt. Geometrically, Take the Point P (*Fig.* 12.) near the top of the plane for the centre of the dial; through P, draw the meridian PE; at P make the angle EPR equal to the complement of the latitude. Take any point G in the line PE, and draw GF perpendicular to PR; and FC perpendicular to GP, and C will be the foot of the ſtile. Through G, draw the contingent line AB, perpendicular to PE, repreſenting the equinoctial.—Take G *g* equal to the thickneſs of the ſtile, and draw *p g q* parallel to PGE.—Make GD and *g q* = GF, and from the centres D and *q* with any radius deſcribe two quadrants LG and M*g*. Divide each quadrant into ſix equal parts or hours. From the centres D *q* draw lines through the points of diviſion, cutting AB in the hour points *m*, *m*; and *n*, *n*, &c. Then lines drawn through the centres P and *p*, through all the points *m*, *n*, &c. will be the hour lines. The half hours, &c. are drawn in the ſame manner. A perpendicular pin FC, or, which is better, the triangle RPG will be the ſtile, which muſt be ſet perpendicular upon the hour lines of XII, PG, and *p g*; the ſtile PR pointing downwards towards the South pole.

When the lines do not interſect within the plane, as at the firſt diviſion towards L and M, biſect the line *q g* in *v*, and draw *v c* parallel to AB, cutting *q c* in *c*; through *c* draw *c h a* parallel to *p q*, and ſet off *h a* = half *gp* drawing *p a* for the hour line.

N. B. The forenoon hours are on the left hand, the afternoon hours on the right.

2d. By calculation and the scale.—The proportion for finding the hour angle in this caſe is. As radius : coſine of latitude : : tangent of hour arch : tangent of hour angle.—In the latitude of London the hour angles for 11 and 1 is 9° 28'; for 10 and 2 = 19°, 45'; for 3, and 9 = 31° 53'; for 4 and 8 = 47° 8'; for 5 and 7 = 66° 42', and for 6 (as uſual) = 90°. Alſo for the half hour, before and paſt 12 = 4° 41'; for half paſt 10, and half paſt 1 = 14° 27'; for half paſt 9 and half paſt 3 = 25° 31' &c.—Theſe being known:

Take any point P near the top of the plane for the centre of the dial; draw the meridian or 12 o'clock line PE, and *p e* parallel to it at a diſtance equal to the thickneſs of the ſtile. With the radius of 60° from a line of chords deſcribe two quadrants from the centres P and *p*; ſet off the ſeveral hour angles, both ways from the lines PE and *p e*, upon the quadrants, viz. 9° 28' for 11 and 1; 19° 45' for 10 and 2, &c. Through the points thus given draw lines from the centres P *p*, for the hour lines.

Laſtly, Make the angle EPR = the complement of the latitude for the ſtile to be ſet upright upon the hour 12.

Case II. *To conſtruct a Direct North Dial.*

The north plane lying in the ſame azimuth with the ſouth, but with its face the oppoſite way, will have the ſame hour angles as a ſouth plane, only the meridian in this will repreſent the midnight hour inſtead of noon; and the hours about it, 11, 10, 9, and 1, 2, 3, are quite uſeleſs, becauſe the ſun in his greateſt north declination riſes but about a quarter before 4 and ſets at a quarter paſt 8.—Alſo the ſun cannot ſhine upon this plane longer than 21 minutes paſt 7 in the morning, nor ſooner than 21 minutes before 5 at night.

To make this dial, is but to turn the ſouth dial upſide down, and leave out all the ſuperfluous hours between 5 and 7, and 4 and 8; and the dial will be complete. There is no reaſon therefore why this ſhould be deemed a different kind of dial to the former, ſeeing that they both agree in the height of the ſtile and hour angles.

N. B. Thoſe hours to the weſt are the morning hours, and thoſe to the eaſt the evening hours.

Case III. *To draw a direct Eaſt Dial. (Fig. 13.)*

A direct eaſt dial is drawn upon the plane of the meridian facing the eaſt. The ſun only ſhines on this plane from his riſing till noon.

On the eaſtern ſide of the plane of the meridian draw a right line AB parallel to the horizon, and to this join AK, making with it an angle KAB, equal to the elevation of the equator: then, with the radius DE, deſcribe a circle, and through the centre D draw EC perpendicular to AK, by which means the circle will be divided into four quadrants. Each of theſe quadrants ſubdivide into ſix equal parts. And from the centre D through the ſeveral diviſions draw the right lines D IV, D V, D VI, D VII, D VIII, D IX, D X, D XI. Laſtly, in D erect a ſtyle equal to the radius D E, perpendicular to the plane; or, on two little pieces perpendicularly fixed in EC, and equal to the ſame radius DE, fit an iron rod, parallel to EC.

Thus will each index at the ſeveral hours project a ſhadow to the reſpective hour lines IV IV, V V, VI VI, &c.

By Calculation and the Scale.

Firſt find the diſtance of the hour lines from 6 o'clock, by this proportion. As radius is to the height of the ſtile in inches, ſo is the tangent of the hour arch from 6, to the diſtance of ſuch hour from the 6 o'clock line.

N. B. If you would have the dial plate juſt to include the 11 o'clock hour, then the height of the ſtile muſt be found by this proportion. As radius is to the length XI E, ſo is the tangent of 15° to the height of the ſtile.

Suppoſe the length of the ſtile to be three inches, then the hour diſtances from VI will be as follow, viz. The diſtance of V and VII. $\frac{4}{5}$ inch; of IV and VIII, 1.73 inches; of III and IX = 3 inches, the height of the ſtile; of X, 5.2 inches; of XI, 11.2 inches.

Theſe being known, and AB and AK being drawn as before, and DC for the 6 o'clock hour line, ſet off the ſeveral diſtances above ſpecified, and they will give the hour lines; alſo DC is the height of the ſtile, which may either be a perpendicular pin or a parallelogram of that height.

N. B. The ſtile muſt either be made exceeding thin on the top part, or a ſpace muſt be left for the thickneſs thereof as has been before ſhewn, and this obſervation is applicable to any other dial.

Case IV. *To draw a direct Weſt Dial.*

A direct weſt dial, is one deſcribed on the weſtern ſide of the meridian. The conſtruction of this dial is perfectly the ſame as that of an eaſt dial, only that its ſituation is inverted. If you look on the back ſide of the paper on which an eaſt dial is drawn, and hold it to the light, you will ſee the true figure of a weſt dial through the paper.

Art. XII. *To draw erect declining Dials.*

Case I. *To draw an erect South declining Dial.*

Geometrically. Let the dial decline to the weſt 36°, and let the latitude of the place be 54°½.

Take the point C, (*Figure* 14.) about the middle of the plane for the foot of the ſtile, through which draw the horizontal line AB, and make CF perpendicular to it, and equal to the perpendicular height of the ſtile. Make the angle CFZ equal to the declination (36°) to the right hand if it decline eaſt; or to the left if weſt, as in this caſe, cutting the horizontal line in Z. Through Z draw PZE perpendicular to AB for the meridian. Take ZF and ſet it from Z to X, in the line AB. Make ∠ZXP = latitude (54½) cutting the meridian in P, the centre of the dial. Through C and P draw PCD for the ſubſtile. Alſo through C draw QQ perpendicular to PD, cutting the meridian in N, for the contingent line. In CQ make CT equal to CF, and draw PT. Take the neareſt diſtance from C to PT, and ſet it from C to D, in the line PD, and draw DN. With the centre D and any radius as DC, deſcribe the ſemicircle SCW. Divide the ſemicircle into parts of 15° for hours. Through theſe points draw lines from the centre D interſecting the equinoctial QQ in the hour points XI, XII, I, II, III. From P, the centre of the dial, draw lines through the hour points, as P XI, P XII, P I, P II, P III, &c. for the hour lines. The ſtile may be either the perpendicular pin FC, or the triangle PCT ſet upright on the ſubſtile PC.

By Calculation and the Scale.

Here there are given the latitude = 54°½, and the declination of the plane = 36°, to find firſt the ſubſtile's diſtance, from XII; 2d, the height of the pole above the plane; and 3d, the plane's difference of longitude.

I. For the diſtance of the ſubſtile, the proportion is, as radius : ſin. declination (36°) :: cotangent latitude (54°½) : tangent of ſubſtile's diſtance, which in this caſe = 22° 45′.

II. For the poles height. As radius : coſine of declination :: coſine of latitude : ſine of the height of the pole, = 28° 1′ = ſtile's height.

III. For the plane's difference of longitude. As ſine latitude : radius :: tangent of declination : tangent of difference of longitude = 41° 45′

Now the hour arches before 12 are found by adding continually 15 to 41° 45′, the difference of longitude; but after 12, by continually ſubtracting 15°, till you come to the ſubſtile; beyond which 15° muſt be continually added to the remainder of the hour in which the ſubſtile falls.

If you calculate for quarters, you muſt add and ſubtract 3° 45′ continually. The hour arches being thus determined, the hour angles are had by the following analogy.

As radius : ſine of ſtile's height :: tangent of hour arch : tangent of hour angle. The hour arches and angles in this caſe are as under:

Hours	Hour Arches	Hour Angles	Hours	Hour Arches	Hour Angles
IX	86° 45′	83° 6	Subſtile	° ′	° ′
X	71 45	54 55	III	3 15	1 32
XI	56 45	35 37	IV	18 15	8 49
XII	41 45	22 45	V	33 15	17 7
I	26 45	13 19	VI	48 15	27 45
II	11 45	5 35	VII	63 15	42 59
Subſtile			VIII	78 15	66 7

The above requiſites being found, take P near the top for the centre of the dial, and draw the meridian PE. Make the angle EPC = 22° 45′, the ſubſtile's diſtance, on the right hand, the declination being weſt; and draw the ſubſtile line PCD. Make the hour angles from the ſubſtile, according to the diſtances in the table, viz. CP IX = 83° 6′; CP X = 54° 55′: CP XI = 35, 37, &c. And thus the hour lines will be formed. Then make the angle CPN = 28° 1′ for the ſtile.

Scholium. The conſtruction would be equally eaſy if the dial declined as much eaſtward; only the forenoon hours, as here deſcribed, would become the afternoon hours on the oppoſite ſide of the dial, and vice verſa; and the ſubſtile which is now placed 3° 15′ before the afternoon hour line of 3, would in that caſe be placed 3° 15′ before the morning hour line of 9. Alſo in finding the hour arches, inſtead of adding or ſubtracting as in the laſt example, the proceſs muſt here be reverſed, uſing ſubtraction in lieu of addition, and addition in the room of ſubtraction.

Case II. *To draw an erect North declining Dial.*

This is done by making a ſouth declining dial, whoſe declination is the ſame and lies the ſame way; for this turned upſide down will be a north declining dial, provided the hours be numbered the contrary way. Thus for a north eaſt decliner make a ſouth eaſt decliner; for a north weſt decliner make a ſouth weſt decliner. The hours before ſun riſe, and ſun ſet muſt be left out. And in drawing the dial the centre H muſt be taken about the middle of the plane, becauſe ſome hours are required here that are not in the ſouth decliner, but theſe will be had by producing the other hour lines through the centre.

SECT. VII.

DIALS INCLINING TO THE HORIZON.

Under this deſcription are all dials whoſe planes are neither horizontal nor vertical, but make with the horizon oblique angles. If the plane of the dial lean forward it is uſually called an incliner; if backward, a recliner. Alſo of each of theſe there are two kinds, viz. direct incliners or recliners; and declining incliners or recliners.

Art. XIII. *To draw a direct inclining or reclining Dial.*

Case I. *To draw a Dial on a plane Parallel to the Equinoctial, or what is uſually called an Equinoctial Dial.*

The plane of this dial reclines from the zenith towards the north in an angle equal to the latitude of the place, and at the poles it becomes an horizontal dial. Wherefore it is only making an horizontal dial by Article I. for the latitude of 90°. In this dial however the hour arches, being equal to the hour angles, which are each = 15°; the dial will be conſtructed by dividing a circle into 24 equal parts, for hour lines, and placing a perpendicular ſtile of any length in the centre.

The ſtile muſt either be a circular pin, of an exceeding ſmall diameter; or otherwiſe an allowance muſt be made for the diameter, by deſcribing a ſmall concentric circle of like radius, and drawing a tangent thereto parallel to the meridian of the plane, for the 12 o'clock hour line, and then the outer circle being divided into parts of 15° each, commencing from the hour line of 12, lines muſt be drawn from each part, to the outer edge of the concentric circle, ſo as to form tangents thereto inclining on each ſide to the 12 o'clock hour line, and to one another, which will be the hour lines required.

N. B. If the dial is conſtructed on the ſouth ſide of the plane, there muſt be hour lines from 6 to 6; but if it is drawn on the north ſide, there need be only the morning and evening hour lines, viz. from the time of ſun riſe (on the longeſt day) till 6; and and from 6 till the time of the ſun's ſetting. The ſun never ſhines on this ſide of the plane, but when he is in north declination.

Case II. *To draw a Dial for any Latitude on a Plane, paſſing through the Poles of the World, and through the Eaſt and Weſt Points of the Horizon, or which is the ſame, an horizontal Dial under the Equinoctial, uſually called a Polar Dial.*

By Art. X. draw an horizontal dial for 0° latitude; or by Art. XI. an erect ſouth dial for the latitude of 90°; or, as the directions in thoſe articles are not ſo well adapted to the preſent caſe, proceed as follows:

By Calculation and the Scale.—As radius is to the ſtile's height, ſo is the tangent of the hour arch, viz. 15°, 30°, 40°, &c. to the diſtance of the hour from the 12 o'clock line. Then thoſe diſtances ſet off on both ſides (*Fig.* 15.) from XII, and C, on the lines AB, and DE, drawn parallel to each other and perpendicular to XII, will give the hour points, and joining I, 1; II, 2; III, 3; &c. and XI, 11; X, 10; IX, 9; &c. they will be the hour lines required; the former being the evening hours, and the latter the morning hours.

N. B. This dial reclines from the zenith towards the north in an angle, equal to the co-latitude.

Case III. *To draw a Dial upon a direct South reclining Plane; or upon a direct North inclining one; whatever may be the Reclination or Inclination.*

1ſt. If it reclines, and the reclination is leſs than the co-latitude, add the reclination to the latitude, and the ſum will be the latitude, where the ſaid dial will become an erect South dial, which may therefore be conſtructed by Article II.

2d. If the reclination be greater than the co-latitude, ſubtract the co-latitude from the reclination, and the remainder will be the latitude, where the dial will be horizontal, which may be made by Article I.

3d. For a North inclining dial, make a dial for the South reclining circle of the plane; then the ſame turned up-ſide down, will be a dial for the North inclining plane; obſerving to number the hours the contrary way from the 12 o'clock hour line.

Case IV. *To make a direct North reclining Dial, or a direct South inclining one, whatever may be the Reclination or Inclination.*

1ſt. If the plane reclines, and the reclination is leſs than the latitude, ſubtract the reclination from the latitude, and the remainder will be the latitude where it will become a direct ſouth dial, to be conſtructed by Art. XI. or add the reclination to the colatitude, and the ſum will be the latitude, where it will be an horizontal dial, to be made by Article X.

2d. If the reclination is greater than the latitude, add the complement thereof to the latitude, and the ſum is the latitude for which an horizontal dial muſt be made by Article X.

3d. In ſouth inclining planes, (by Art. XI.) make a direct ſouth dial, for a latitude which is equal to the difference between the given latitude and proclination. If the proclination be greater than the latitude, the dial will belong to ſouth latitude, and muſt be made by Art. X. but the angle of the ſtile will lie the contrary way upon the meridian. A north reclining dial, becomes a ſouth inclining one when turned upſide down.

Case V. *To make an Inclining or Reclining Eaſt Dial.*

By Calculation and the Scale.—The requiſites to be found are, 1ſt. The height of the pole above the plane. 2d. The ſubſtile's diſtance from 12 o'clock. 3d. The plane's difference of longitude, for which we have the following proportions.—1ſt. As radius : coſine of reclination (or proclination) : : tangent of latitude : tangent of the ſubſtile's diſtance from 12 o'clock, running upwards towards the north, or downwards towards the ſouth.—2d. As radius : ſine of latitude : : ſine of reclination (or proclination) : ſine of ſtile's height.—3d. As radius : coſine of latitude : : tangent of reclination, &c. : cotangent of the plane's difference of longitude. To find the hour angles, the analogy is as radius : ſine of ſtile's height : : tangent of the hour arch from the ſubſtile : tangent of the hour angle. The hour arches are found by continually adding and ſubtracting 15° to and from the plane's difference of longitude; the ſaid difference of longitude being one of the hour arches.

Let the lat. be 54°½, and the reclination 21°, then the ſubſtile's diſtance will be 52° 37′; the ſtile's height 16° 58′; and the plane's difference of longitude 77° 26′. Alſo the hour arches and hour angles are as below.

Hours	Hour Arches	Hour Angles	Hours	Hour Arches	Hour Angles
3	57° 34′	24° 40′	8	17° 26′	5° 14′
4	42 34	15 0	9	32 26	10 30
5	27 34	8 40	10	47 26	17 37
6	12 34	3 43	11	62 26	29 12
	Subſtile		12	77 26	52 37
7	2 26	0 43			

The requiſites being found, draw PI (*Fig.* 16.) parallel to the horizon at the bottom of the plane, for the 12 o'clock line; or at the top of the plane if it inclines, in which take any point, as P, for the centre of the dial, toward the left hand. Make the angle IPV on the right hand = ſubſtile's diſtance from the meridian (= 52° 37′) and draw the ſubſtile PV. Make the angle VPT = ſtile's height = 16° 58′, and draw the ſtile PT. Make the hour angles on each ſide of the ſubſtile according to their proper quantities, as found above, and the ſeveral lines will be the hour lines required.

Case VI. *To make an inclining or reclining Weſt Dial.*

This is made as is the eaſt incliner, &c. only the angle PGH, which is equal to the co-latitude muſt be taken on the right hand for a weſt recliner, but to the left hand for an eaſt recliner; and the meridian PI will be at the bottom of the plane, if it reclines; but at the top if it inclines. The hours alſo muſt be reckoned the contrary way in a weſt recliner. N. B. The back ſide of an eaſt incliner, &c. makes a weſt recliner, &c.

Art. XIV. *To draw a Declining, Inclining, or Reclining Dial.*

Case I. *Let it be required to draw a South declining reclining Dial, viz. one whoſe plane declines weſtward 25°, and reclines 15°, in latitude 54½.*

By Calculation and the Scale.—The requiſites to be found, are 1ſt, the height of the meridian; 2d, the height of the pole above the plane; 3d, the diſtance of the ſubſtile from the hour line of 12; and 4th, the plane's difference of longitude.

1ſt. As ſine of reclination : radius : : cotangent declination : tangent of height of the meridian. 2d. As radius : coſine declination : : cotangent of the reclination : tangent of an arch, A; take the difference between A, and the latitude, which call B. If A is leſs than the latitude, your pole is elevated; if greater, the oppoſite pole is elevated.—Then as the cotangent of B : coſine of reclination : : ſine of declination : tangent of the ſubſtile's diſtance from 12. N. B. The ſubſtile runs upwards towards the north in reclining South plane; and their oppoſite incliners. 3d, As coſine of ſubſtile's diſtance : coſine of B : : radius : ſine of ſtile's height; and 4th, As ſine of B : radius : : ſine of ſubſtile's diſtance : ſine of plane's difference of longitude. The plane's difference of longitude will be the hour arch of 12, and the reſt of the hour arches will be had by adding thereto and ſubtracting therefrom 15°, 30°, 45°, &c. and then the hour angles will be found thus. As radius : ſine of ſtile's height : : tangent of hour arch : tangent of hour angle.

In this example the height of the meridian is 83°, 9′; the ſubſtile's diſtance 8°, 1′; the ſtile's height 17°, 19′, and the plane's difference of longitude, 25°, 19′. The hour arches and angles alſo are as under.

Hours	Hour Arches	Hour Angles	Hours	Hour Arches	Hour Angles
7	79° 41′	58° 33′		Subſtile	° ′
6	64 41	32 11	1	10 19	3 7
5	49 41	19 20	12	25 19	8 1
4	34 41	11 38	11	40 19	14 11
3	19 41	6 5	10	55 19	23 16
2	4 41	1 29	9	70 19	39 46
	Subſtile		8	85 19	74 37

Theſe being known, the conſtruction is as follows, draw the horizontal line *h*H (*Fig.* 17.) near the bottom of the plane, in which take a point H, to the right, if the declination be weſt, but to the left if the declination be eaſt. Draw the line ZH, making the angle *h*HZ = 83, the height of the meridian for the 12 o'clock line. Take any point P near the top, when A is greater than the latitude, otherwiſe near the bottom, and draw the ſubſtile PV (to the right for weſt declination) making the angle HPV = 8° 1′, the ſubſtile's diſtance. From P draw the hour lines, making angles with the ſubſtile at P, according to the reſpective hour angle as above found, for the ſeveral hour lines required. Alſo draw PT, making the angle VPT = 17° 9′, the ſtile's height, ſo will PTC be the ſtile or gnomon.

Case II. *To draw a North declining, reclining, or inclining Dial.*

North declining reclining dials may be made, as deſcribed in the laſt caſe; for a ſouth-weſt recliner turned upſide down becomes a north-weſt *incliner*; and a ſouth-eaſt *recliner* turned upſide down, becomes a north-eaſt *incliner*, and vice verſa; the quantities of the declination and inclination remaining the ſame; but the hours muſt be numbered the contrary way.

Alſo if a dial be turned upſide, the backſide thereof (ſuppoſing the hour lines, &c. to appear through the plane) will be its oppoſite incliner.

Having treated on all the various kinds of dials that come under a methodical deſcription of dial planes, I ſhall add ſome uſeful Articles, with another caſe or two of Dialling, not properly coming under the foregoing heads.

SECT. VIII.

USEFUL ARTICLES, &c.

Art. XV. *Having the Situation of any direct South inclining Dial Plane, to find the Hour of the Day when the Sun leaves the North Side to ſhine on the South Side thereof.*

Say, as radius : tangent of ſun's declination : : tangent of the height of the pole above the plane : coſine of the hour angle at the pole from noon which reduced into time (by allowing 15° to an hour) ſhews how long before or after noon, the ſun begins to ſhine on the South ſide.

Art. XVI. *To find the Hour of the Day when the Sun leaves one Side of a Vertical declining Plane to ſhine on the other.*

Find the time from noon (by the laſt Article) when the ſun leaves one ſide of a direct north or ſouth plane to ſhine on the other; then, if the plane declines eaſt, to the time ſo found, add the plane's difference of longitude in time, and the ſum will be the diſtance of time before noon, when the ſun leaves the north ſide. Alſo ſubtract the plane's difference of longitude from the time found, and you will have the time of leaving the South ſide.—But if the plane declines weſt, the ſaid difference will ſhew the diſtance of time before noon, when the ſun begins to ſhine on the ſouth ſide; and the ſum will be the time when he leaves the ſouth ſide.

Art. XVII. *To find the Hour of the Day when the Sun goes off the Eaſt Side of an Eaſt reclining Dial to ſhine on the Weſt Side.*

Say, as radius : tangent of the ſun's declination : : tangent of the poles height above the plane, to the coſine of the hour angle from 12, at the pole, which will be greater than 90°, when the ſun's declination is North. Then ſubtract the plane's difference of longitude from this angle, and the remaining angle, converted into time, gives the hour after 12 at noon, when the ſun leaves the Eaſt ſide.

Art. XVIII. *To find the Hour on a given Day, when the Sun comes on or goes off the South Side of a South reclining Plane, declining alſo Eaſt or Weſt.*

Find the height of the pole above the plane, and the plane's difference of longitude; and alſo the hour angle, as if it was a direct South plane, by Article XV. to which add the plane's difference of longitude, and it will give the hour angle from noon when the ſun comes upon the given plane, if an Eaſt decliner; alſo from the hour angle ſubtract the plane's difference of longitude for the time of his leaving the plane; the reverſe of theſe caſes will give the hour angles from noon for an Eaſt decliner.

Art. XIX. *Having a North reclining Dial Plane, declining Eaſt or Weſt, to find the Hour of any Day when the Sun goes upon the North Side.*

The hour angle being found, as in the laſt Article, the difference between it and the plane's longitude reduced to time, will ſhew the diſtance of time from noon, when the ſun comes upon the north ſide of a weſt decliner, which is before noon, when the plane's longitude is the greater, otherwiſe after noon. The direct contrary of this obtains in an Eaſt decliner.

Art. XX. *To find what Latitude a Dial is made for.*

Meaſure the angle between 12 and any hour line; take the hour arch belonging to it, and ſay, As the tangent of the hour arch : tangent of the hour angle : : radius : ſine of latitude in an horizontal dial, or the coſine of latitude for a direct ſouth or north dial.

Art. XXI. *To find the Hour of the Night by the Moon's ſhining upon a Sun-Dial.*

From an ephemeris, or almanack, take the time of the moon's ſouthing. Obſerve how many hours, and minutes the ſhadow of the dial wants of 12 o'clock, and ſubtract them from the time of ſouthing for the hour of the night. But if the ſhadow be after 12, add the ſaid hours and minutes to the time of her ſouthing; rejecting 12, if it exceed, and you will have the hour of the night.

Scholium. In fixing any dial, the three following directions muſt be obſerved. 1ſt. That the horizontal line be placed parallel to the horizon. 2d. That it be placed ſo as to have its proper declination; and 3d. That it may alſo have its proper degree of reclination or proclination.

Art. XXII. *To draw all the Primary Dials, on the ſame Block or Poſt.*

1. Let the plane ABCD (*Fig.* 18.) in the proper poſition of the block, be ſuppoſed horizontal; and thereon deſcribe a horizontal dial.

2. Draw the right lines EM and FL parallel to DC, which, accordingly, in the proper poſition of the block, will be parallel to the horizon: then let the plane BNMC make an angle with EM, equal to the elevation of the pole CME; and thereon deſcribe an upper polar dial.

3. Let the oppoſite plane, ADE, make with EM an angle DEM, equal to the elevation of the equator; and on this draw an upper equinoctial dial.

4. Let the plane, KLHI, make with FL an angle HLF, equal to the elevation of the equator; and on this inſcribe a lower equinoctial dial.

5. Let the oppoſite plane, FG, make with FL an angle, GFL, equal to the elevation of the pole; and here draw a lower polar dial.

6. Let the plane MNKL, and the oppoſite one EF, be perpendicular to FL; and on that draw a ſouth dial, and on this a north dial.

7. On the plane EMLF deſcribe a weſt dial; and on the oppoſite plane an eaſt dial.

If, then, the block be ſo placed, as that the plane, MNLK, looks to the ſouth, and the plane of the meridian biſect it in the line of 12 o'clock in the horizontal dial ABCD, and ſouth dial MNKL, all the hours of the day will be indicated by ſeveral planes at once.

Art. XXIII. *To deſcribe an Univerſal Equinoctial Dial,* (*Fig.* 19.)

Join two metal, or ivory planes, ABCD, and CDEF, ſo as to be moveable at the joint. On the upper ſurface of the plane ABCD, deſcribe an *upper equinoctial dial,* and upon the lower a *lower,* as already directed; and through the centre I drive a ſtile. In the plane DEFC cut a box, and put a magnetical needle G therein: fit on the ſame plane a braſs quadrant nicely graduated, and paſſing through a hole cut in the plane ABCD. Now, ſince this may be ſo placed, by means of the needle, as that the line I 12 ſhall be in the plane of the meridian; and, by means of the quadrant, may be ſo raiſed, as that the angle BCF ſhall be equal to the elevation of the equator; it will ſerve as a dial in any part of the world. When the ſun is in the equator, theſe dials can be of no uſe.

Art. XXIV. *To make a Dial on the Surface of a Sphere.* (*Fig.* 20.)

Let AEBQ be a ſphere. Mark two oppoſite points therein for the poles, of which P is one. At an equal diſtance from the poles deſcribe the equinoctial EQ, which divide into 24 equal parts for hours. Then let the point which is on the meridian PB be marked with 6; and the other hour points as in the figure. Thoſe placed above the equinoctial are the forenoon hours; and thoſe below the equinoctial the afternoon hours. The globe muſt be fixed ſo in the ſun that the pole P may be elevated above the horizon, ſo that its axis may point directly to the pole, and the point 6 muſt be on the top, ſo that the circle P 6 B may be in the meridian. Then as the ſun conſtantly illuminates half the globe, the circle, terminating the enlightened part, will ſhew the hour of the day. And 12 o'clock will be ſhewn at two places, namely, at E and Q.

Art. XXV. *To draw a Dial upon the Ceiling of a Room, that will ſhew the Hour by Reflection.*

Place a ſmall piece of a looking glaſs exactly horizontal in a window, on which the ſun ſhines, meaſure the perpendicular diſtance of the glaſs from the ceiling, for the height of the ſtile, and where the perpendicular cuts the ſealing is the foot of the ſtile. Then having the height of the ſtile and its foot, make an horizontal dial thereto upon the ceiling by Art. X. and it is done.

N. B. Inſtead of a glaſs you may uſe a little water, which, if a glaſs is not perfectly horizontal, will be more correct; for water of itſelf will have its ſurface horizontal; alſo water being always in motion by the agitation of the air, will cauſe the point of reflection on the ceiling to be the more eaſily diſtinguiſhed. When a glaſs is uſed, the error, if any, in its horizontal poſition, will be doubled by reflection.

Art. XXVI. *To draw Meridian Lines in a Dial, to ſhew when it is Noon, at any particular Places on the Earth.* (*Fig.* 21.)

The meridian of any place is eaſily drawn in a dial, if the longitude thereof be known. Thus reduce the difference of longitude between that place and the place for which the dial is made into time, and reckon ſo many hours and minutes from 12 upon your dial towards the weſt, if the place lies eaſt; or towards the eaſt if the place is weſt: then from the point to which they reach, draw a line to the center; and when the ſhadow falls upon ſuch line, the ſun is in the meridian of the ſaid place; or having the difference of longitude, or the hour arch, the hour angle may be found, as has been before ſhewn.

In digeſting this Treatiſe, I have ſelected, from the moſt approved authors, every thing that appeared valuable; and notwithſtanding I have ſtudied brevity, have fully enlarged where the ſubject required. And as a neceſſary introduction, have treated amply on the Gnomonic Projection. In this Treatiſe I have conſulted various Authors on the ſubject, particularly Emerſon; nor have I omitted any thing that could illuſtrate the art. I have alſo been ſtudious to ſelect the beſt conſtructions and modes of calculation, and given copious deſcriptions of thoſe Dials which are of moſt general uſe; ſo that I have brought into this compaſs a complete Practical Syſtem.

ROBERT MOODY.

Excise Office, London.

DIALOGISM, Διαλογισμος, in rhetoric, is uſed for the ſoliloquy of perſons deliberating with themſelves. We have an inſtance of it in Virgil, where Dido ſays,

> *En quid agam? rurſuſne procos irriſa priores*
> *Experiar?* &c.

In which ſenſe, it is diſtinguiſhed from dialogue. Voſſ. Rhet. lib. v. p. 355.

DIALOGUE, a converſation of two or more perſons, real or feigned, either by word or mouth, or in writing. The word is formed from the Latin *dialogus*, of the Greek διαλογος, which ſignifies the ſame.

Dialogue is greatly recommended by many authors, and is the moſt ancient form of writing, and that wherein the firſt authors wrote moſt of their pieces. The archbiſhop of Cambray gives a fine account of the advantages of dialogue, at the head of his paſtorial inſtruction. The ſacred writers, and the fathers, Athanaſius, Baſil, Chryſoſtom, &c. have uſed this mode of inſtruction.

Antiquity made uſe of dialogue, not only on humorous and comical ſubjects, as Lucian did, but alſo on the moſt ſerious and abſtract; ſuch are the dialogues of Plato, and thoſe of Cicero, which turn altogether on ſubjects of philoſophy, or politics. Among the moderns, the principal dialogiſts are M. de Fenelon, archbiſhop of Cambray; M. Paſchall, in his Provincial Letters; F. Bouhours, in his Entretiens d'Ariſte, and d'Eugene; M. Fontenelle, in his Dialogues of the Dead, and Plurality of Worlds; Addiſon, Hurd, and Lord Lyttelton.

A dialogue conſiſts of two parts, an introduction and the body of the diſcourſe. The introduction acquaints us with the place, time, perſons and occaſion of the converſation. However, the introduction ought not to be too long and tedious. Mr. Addiſon complains of this fault: for though, as he ſays, ſome of the fineſt treatiſes of the moſt polite Latin and Greek writers are in dialogue, as many very valuable pieces, of French, Italian, and Engliſh appear in the ſame dreſs; yet in ſome of them there is ſo much time taken up in ceremony; that before they enter on their ſubject, the dialogue is half over.

In Dialogue, all wrangling, peeviſhneſs, and obſtinacy ſhould be avoided; and nothing appear but good humour and good breeding, with a readineſs to ſubmit to conviction, as evidence preſents itſelf. Cicero has given us two characters of this kind in Craſſus and Antony; from whom Mr. Addiſon ſeems to have taken his Philander and Cynthio, in his Dialogues on the Uſefulneſs of Ancient Medals.

The methods of compoſing dialogues are various: ſometimes a writer relates a diſcourſe by way of narrative, which paſſed between other perſons; ſuch are the dialogues of Cicero, and of Mr. Addiſon laſt mentioned: at other times the ſpeakers are introduced in perſon, Cicero's Dialogues of Old Age, of Friendſhip, and of the Parts of Oratory, are written in this manner. Plato and Lucian generally chuſe this method. As for the ſtile of a dialogue, the eaſy ſtile is the proper character in which they ſhould generally be written. Ward's Orat. vol. ii. p. 221, &c.

DIALTHÆA, in pharmacy, an unguent thus called from its baſis, which is the root of the althæa, or marſhmallow. It conſiſts of mucilages drawn from that root, and from linſeed and fenugreek-ſeed. The other ingredients are common oil, wax, reſine and turpentine.

DIALISIS, in grammar, a character conſiſting of two points placed over two vowels of a word, which would otherwiſe make a diphthong, but are hereby parted into two ſyllables; as in Moſaic. See DIÆRESIS.

DIAMETER, from δια, and μετρειν, to meaſure, in geometry, a right line paſſing through the centre of a circle, and terminated on each ſide by the circumference thereof. See Syſtem of GEOMETRY.

DIAMETER, in aſtronomy. The diameters of the heavenly bodies are either apparent, i. e. ſuch as they appear to the eye; or real, i. e. ſuch as they are themſelves. See Syſtem of ASTRONOMY, Sect. VIII.

DIAMETER *of a Column*, is its thickneſs juſt above the baſe. From this the model is taken, which meaſures all the other parts of the column. See Syſtem of ARCHITECTURE, Plate VI.

DIAMOND, in natural hiſtory, a genus of precious ſtones, of a fine pellucid ſubſtance, of great hardneſs, ſeldom fouled by any admixture of earthy or other coarſe matter, ſuſceptible of elegant tinges from metalline particles, giving fire with ſteel, not fermenting with acid menſtruums, and of one ſimple and permanent appearance in all lights. The goodneſs of diamonds conſiſts in their water, or colour, luſtre, and weight. The moſt perfect colour is the white. Their defects are veins, flaws, ſpecks of red or black ſand, and a bluiſh or yellowiſh caſt.

Diamonds are found in the Eaſt Indies, principally in the kingdoms of Golconda, Viſapour, Bengal, and the iſland of Borneo. There are four mines, or rather two mines and two rivers, whence diamonds are drawn. The mines are, 1. That of Raolconda, in the province of Carnatica, five leagues from Golconda, and eight or nine from Viſapour. It has been diſcovered about 250 years. 2. That of Gani, or Coulour, ſeven days journey from Golconda, eaſtwardly. It was diſcovered about 170 years ago by a peaſant; who, digging in the ground, found a natural fragment of twenty five carats. 3. That of Soumelpour, a large town in the kingdom of Bengal, near the diamond mine: this is the moſt ancient of them all. It ſhould rather be called that of Goual, which is the name of the river, in the ſand whereof theſe ſtones are found. Laſtly, the fourth mine, or rather the ſecond river, is that of Succudan, in the iſland of Borneo.

DIAMOND *Mine of Raolconda*. In the neighbourhood of this mine the earth is ſandy, and full of rocks, and corpſe: in theſe rocks are found ſeveral little veins, of half, and ſometimes a whole inch broad, out of which the miners, with a kind of hooked irons, draw the ſand, or earth, wherein the diamonds are; breaking the rocks when the veign terminates, that the track may be found again, and continued. When a ſufficient quantity of earth, or ſand, is drawn forth, they waſh it two or three times, to ſeparate the ſtones therefrom: the miners work quite naked, except a thin linen cloth before them; and, beſides this precaution, they have likewiſe inſpectors, to prevent their concealing of ſtones; which, however, in ſpite of all their care, they frequently find means to do, by watching opportunities, when they are not obſerved, and ſwallowing them down.

DIAMOND *Mine of Gani or Coulour*. In this mine are found a great number of ſtones from ten to forty carats, and even more; and it was there that the famous diamond of Aureng-Zeb, the great mogul, which, before it was cut, weighed 793 carats, was found. The miners dig twelve or fourteen feet deep, and till ſuch time as they find water; then they ceaſe digging: and the water, thus found, ſerves to waſh the earth two or three times; after which, it is let out at an aperture reſerved for that purpoſe. This earth being well waſhed, and well dried, they ſift it in a kind of open ſieve, or riddle, much as we do corn in Europe; then they thraſh it and ſift it afreſh; and, laſtly, they ſearch it well with the hands, to find the diamonds. They work naked here, as in the mine of Raolconda, and are watched, after the like manner, by inſpectors.

DIAMOND *Mine of Soumelpour, or River Goual*. When the ſand of the river, have been well examined, the miners proceed to take up that wherein they judge diamonds likely to be found; which is done after the following manner: they dam the place round with ſtones, earth, and faſcines: and lading out the water, dig about two feet deep: the ſand, thus got, is carried into a place walled round on the bank of the river. The reſt is performed after the ſame manner as at Coulour, and the workmen are watched with equal ſtrictneſs.

DIAMOND *Mine in the Iſland of Borneo, or River of Succudan*. We are but little acquainted with this mine; the prince who reigns in that part of the iſland not allowing ſtrangers to have any commerce in theſe ſtones: though there are very fine ones to be brought at Batavia, brought thither by ſtealth. They were anciently imagined to be ſofter than thoſe of the other mines; but experience ſhews, they are in no reſpect inferior to them.

Diamond mines were diſcovered about the year 1728 in the Braſils belonging to the king of Portugal, who, in the year 1740, let them to a company at Rio Janeiro, for a certain ſtipulated annual rent, which is ſaid to be 130,000 cruſades, on condition that the ſaid company employ no more than ſix hundred ſlaves in working them; ſince which time the value of diamonds is diminiſhed.

The diamond we have already obſerved, is the hardeſt of all precious ſtones. It can only be cut, and ground, by itſelf in its own ſubſtance. To bring it to that perfection which augments its price ſo conſiderably, they begin by rubbing ſeveral againſt each other, while rough, after having firſt glued them to the ends of two wooden blocks, thick enough to be held in the hand; it is the powder thus rubbed off the ſtones, and received in a little box for the purpoſe, that ſerves to grind and poliſh the others.

Diamonds are cut and poliſhed by means of a mill, which turns a wheel of ſoft iron ſprinkled over with diamond duſt mixed with oil of olives: the ſame duſt, well ground, and diluted with water and vinegar, is uſed in the ſawing of diamonds; which is performed with an iron or braſs wire, as fine as a hair: ſometimes, in lieu of ſawing the diamonds, they cleave them, eſpecially if there be any viſible plates in them; but the Europeans are not uſually daring or expert enough, to run the riſque of cleaving, for fear of breaking.

Rough DIAMOND, is that not yet cut, but juſt as it comes out of the mine. It muſt be choſen uniform, of a good ſhape, tranſparent, not quite white, and free from flaws and ſhivers.

Black, rugged, dirty, flawey, veiny ſtones, and all ſuch as are not fit for cutting, they uſe to pound in a ſteel mortar made for that purpoſe; and, when pulveriſed, they ſerve to ſaw, cut, and poliſh the reſt.

Brilliant DIAMOND, is that cut in faces both at the top, and bottom; and whoſe table, or principal face at the top is flat.

To make a compleat ſquare brilliant, if the rough diamond be not found to be of the figure here deſcribed, it muſt be made ſo. And if the work be perfectly executed, the length of the axis will be equal to the ſide of the ſquare baſe of the pyramid. Jewellers then form the table and collet, by dividing the block or length of the axis into eighteen parts.

The parts of the ſmall work which complete the brilliant, or the ſtar and ſkill facets, are of a triangular figure. Both of theſe partake equally of the depth of the upper ſides, from the table of the girdle, and meet in the middle of each ſide of the table and girdle, as alſo at the corners. Thus they produce regular lozenges on the four upper ſides and corners of the ſtone. The triangular facets, on the under ſides, joining to the girdle, muſt be half as deep again as the above facet to anſwer to the collet part.

The ſtone here deſcribed is ſaid to be a full ſubſtanced brilliant. If the ſtone be thicker than in the proportion here mentioned, it is ſaid to be an over-weighed brilliant. If the thickneſs be leſs than in this due proportion, it is called a ſpread brilliant. The beauty of brilliants is diminiſhed by their being either over-weighed or ſpread. The true proportion of the axis or depth of the ſtone to its ſide, is as 2 to 3. Brilliants are diſtinguiſhed iuto ſquare, round, oval, and drops, from the figure of their reſpective girdles.

Roſe DIAMOND, is that quite flat underneath, but its upper part cut in diverſe little faces, uſually triangles, the uppermoſt whereof terminate in a point.

The taſte which now prevails of converting roſe-diamonds into brilliants, is condemned by Mr. Jefferies; unleſs the roſe-diamonds be over-weighed. He thinks, that the diſplay of beauty in roſe-diamonds, is often preferable to that of brilliants. See his Treatiſe on Diamonds, p. 32, 35.

Table DIAMOND, is that which has a large ſquare face at the top, encompaſſed with four leſſer.

Complexions of DIAMONDS. The fineſt diamonds are thoſe of a complexion like that of a drop of the cleareſt rock water: and if ſuch ſtones be of a regular form, and truly made, as alſo free from ſtains, fouls, ſpots, ſpecks, flaws, and croſs veins, they will have the higheſt luſtre of any, and be eſteemed the moſt perfect.

If diamonds be tinctured yellow, blue, green, or red, in a high degree, they are next in eſteem. But if they partake of theſe colours only in a low degree, it greatly ſinks their value.

The firſt water in diamonds means the greateſt purity and perfection of their complexion, which ought to be that of the cleareſt drop of water. When diamonds fall ſhort in this perfection they are ſaid to be of the ſecond or third water, &c. till the ſtone may be properly called a coloured one: for it would be an impropriety to ſpeak of a diamond imperfectly coloured, or having other defects, as a ſtone of a bad water only.

Mugnitude of DIAMONDS. The largeſt oriental diamond in the world belongs to the great Mogul. It weighs 279 carats. According to the computation of M. Tavernier, this diamond is worth 779,244l. ſter. but by the tables of Mr. Jefferies, its value is only 624,962l. That known in France under the name of grand ſancy, by corruption of *cent ſix*, which is one of the crown jewels, weighs 106, carats; governor Pitt's diamond, purchaſed by the late duke of Orleans for Louis the XV. king of France, weighs 136¾ carats, and is ſaid to have been bought for 125,000l. and the diamond of the great duke of Tuſcany, weighs 139½ carats.

According to Mr. Jefferies's rule, that the value of diamonds is in the duplicate ratio of their weights, and that a manufactured diamond of one carat is worth at a medium 8l. the great mogul's diamond muſt be valued at above 624962l. this being the value of a diamond of 279½ carats.

It muſt be obſerved, however, that defects in the water, or ſhape, red or black ſpots, ſhivers, and other failings, frequently found in theſe ſtones, reduce the price by one third, and ſometimes more.

When diamonds are fouled with a yellow or brown colour, it is a common practice among jewellers to put them in a fierce fire; this diveſts them of their colours, without doing them the leaſt ſenſible injury. Du-Fay, in Mem. Acad. Paris, 1735.

As to brilliant diamonds of very ſmall cut, the price is always leſs by one third than that of diamonds of a larger cut, though the weights be the ſame: the reaſon is, that the latter ſhew themſelves a great deal more when ſet in their collets, than the former.

DIAMOND is an inſtrument of conſiderable uſe in the glaſs manufactory, for ſquaring the large plates, or pieces; and among glaziers for cutting their glaſs.

DIAMOND, in heraldry, is uſed to expreſs the black colour in the atchievements of noblemen.

DIAMOND *Powder* is of great uſe for grinding hard ſubſtances. And Mr. Boyle obſerves, that though it be much dearer than emery, yet it makes ſo great diſpatch, and the tools employed laſt ſo much longer, as greatly to over-balance the cheapneſs of the emery.

DIANA, the goddeſs of hunting, in heathen mythology, was the daughter of Jupiter and Latona. She is called Hecate in hell, Diana on earth, and Phœbe in heaven. She was famous for her chaſtity. The moſt known character of this goddeſs is that of her preſiding over woods, and delighting in hunting. Accordingly the *Diana venatrix*, or goddeſs of the chace, is frequently repreſented in ancient ſtatues; and deſcribed by the Roman poets, as running, with her veſt ſhortened and girt about her, and yet flying back with the wind. She often is repreſented with her quiver on her ſhoulder; and ſometimes holds a javelin, but more uſually her bow in her right hand. The ſtatues of Diana were frequent in the woods, where ſhe is preſented as hunting, bathing and reſting herſelf after fatigue. When ſhe is repreſented as the intelligencer that preſides over the moon, ſhe appears in a car, drawn by ſtags, or by dogs, but more commonly by horſes of a perfectly white colour, with a lunar crown or creſcent on her forehead. Spence's Polymetis, p. 100, 102, 104.

DIANDRIA, in botany, the ſecond claſs of plants, which have hermaphrodite flowers, with two ſtamina or male parts in each. The word is formed of the Greek δις, *twice*, and ανηρ, *male*. Of this claſs of plants, which comprehends three orders, viz. the monogynia, digynia, and trigynia, are the jeſſamine, phillyrea, olive, roſemary, &c. See Syſtem of BOTANY, Claſs II. and Plate IV.

DIANTHERA, in botany, a genus of the monogynia order of the diandria claſs of plants. This plant grows naturally in Virginia, and other parts of North America. Linnæus enumerates two ſpecies. See Syſtem of BOTANY, Sect. V. and Plate IV.

DIANTHUS, in botany, a genus of the digynia order belonging to the decandria claſs of plants. There are a great number of ſpecies, but not more than four that have any conſiderable beauty, as garden flowers, each of which furniſhes ſome beautiful varieties. See Syſtem of BOTANY. Sect. V. Plate IV.

DIAPASON, from δια, *by*, and πας, *all*, in muſic, a muſical interval, otherwiſe called *octave*; ſo called, becauſe it contains all the poſſible diverſities of ſound. See Syſtem of MUSIC.

DIAPASON, among muſical inſtrument makers, is a kind of rule, or ſcale; whereby they adjuſt the pipes of their organs, and cut the holes of their flutes, hautboys, &c. in due proportion, for performing the tones, ſemi-tones, and concords, juſtly.

DIAPASON is alſo the name of two ſtops of an organ, viz. the open and ſtopped.

DIAPEDESIS, Διαπηδησις, in medicine, an ouſing of blood through the coats of the veins, or arteries; occaſioned either by the blood's becoming too much diſſolved, or attenuated; or by the pores of the veſſels becoming too patent or open. The word is compounded of δια, *through*, and πηδαω, *I leap*.

DIAPHANEITY, the quality of a tranſparent body; or that which denominates it ſuch. See TRANSPARENCY.

DIAPHANOUS, in philoſophy, a thing tranſparent, or that gives paſſage to the rays of light; as water, air, glaſs, talc, fine porcelain, &c. The word is formed of δια, *through*, and φαινω, *I ſhew*.

DIAPHONICS, from δια, *through*, and φωνη, *ſound*, is ſometimes uſed for the ſcience of refracted ſound, as it paſſes through different mediums.

DIAPHORETIC, in medicine, is applied to remedies that promote the expulſion of humours by inſenſible perſpiration. Diaphoretic is much of the ſame import as ſudorific: except that the latter promotes ſenſible, and the former inſenſible perſpiration. Their only difference, therefore, is in the degree of activity.

DIAPHRAGM, *Diaphragma* in anatomy, a part, popularly called the midriff, and by anatomiſts *ſeptum tranſverſum*. It is a nervous muſcle, ſeparating the breaſt, or thorax, from the abdomen, or lower venter; and ſerving as a partition between the natural and the vital parts as they are called. It was Plato, as Galen informs us, that firſt called it diaphragm, from the verb διαφραττειν, *to ſeparate*, or *be between two*. Till his time it had been called φρενες, *underſtanding*; from a notion that an inflammation of this part produced phrenſy: which is not at all warranted by experience, no more than that other tradition, that a tranſverſe ſection of the diaphragm with a ſword, cauſes the patient to die laughing. See Syſtem of ANATOMY, Plate V. *Fig.* 3, Letter N, alſo Plate IV. *Fig.* 3.

DIAPHRAGMATIC, is applied to the arteries, veins, and nerves, diſtributed through the diaphragm. They are alſo called phrenic, or phrenetic.

DIAPHTHORA, from διαφθειρειν, *to corrupt*, is uſed by Galen and Boerhaave, to denote the corruption of the aliments in the ſtomach, and by Hippocrates for the corruption of the fœtus in the womb, and abortion.

DIAPORESIS, Διαπορησις, in rhetoric, is uſed to expreſs the heſitation, or uncertainty of the ſpeaker. We have an example in Homer, where Ulyſſes going to relate his ſufferings to Alcinous, begins thus:

> Τι πρωτον, τι δ' επειτα, τι δ' υσατιον καταλεξω?
> *Quid primum, quid deinde, quid poſtremo alloquar?*

This figure is moſt naturally placed in the exordium or introduction to a diſcourſe.

DIAPRE', or DIAPERED, in heraldry, a dividing of a field into planes, or compartments, in the manner of fretwork; and filling it with variety of figures. This chiefly obtains on bordures, which are diapered, or fretted over, and the frets charged with things proper to bordures.

DIARRHODON, Διαρροδον, in pharmacy, a name given to divers compoſitions, wherein roſes are a principal ingredient. The word is formed δια, and ροδον, *roſe*.

DIARRHOEA, Διαρροια, in medicine, a looſeneſs, or flux of the belly; or a profuſe evacuation of liquid excrements by ſtool. The word is formed of the Greek δια, *through*, and ρεειν, *to flow*. See Syſtem of MEDICINE.

The word in general is uſed for any kind of flux of the belly:

but properly for that wherein the humour, or excremeut, flows out either pure, or mixed, with or without pain, in a fluid ſtate.

DIARTHROSIS, in anatomy, a kind of articulation, or juncture of the bones, which being pretty lax, affords room for a manifeſt motion. The word comes from δια, and αρθρον, *juncture, aſſemblage*. It is oppoſite to ſynarthroſis, wherein the articulation is ſo cloſe, that there is no ſenſible motion at all.

DIARY, a term uſed for a journal, or day book, containing an account of every day's proceedings. Thus we ſay diaries of the weather, &c.

DIASENNA, in pharmacy, a ſoft, purgative electuary, thus called ſenna, which is its baſe.

DIASTASIS, from διϛημι, *I ſet apart*, a word uſed by the writers, in medicine, in many different ſenſes. It is frequently uſed as a name for that ſeparation of the bones, when they naturally recede from one another. Sometimes it is uſed as the term for an interſtice, as that between the ulna and radius, or between the tibia and fibula. Sometimes it is put for a diſtention of the muſcles in convulſions; and, when applied to the ſtomach, it is made to ſignify an inclination to vomit.

DIASTOLE, in anatomy, expreſſes that motion of the heart, and arteries, whereby thoſe parts dilate, or diſtend themſelves: the other oppoſite motion being called the ſyſtole of the heart and arteries, wherein they contract themſelves. The word is Greek, formed from the verb διαϛελλειν, *to ſeparate, open, dilate*. See Syſtem of ANATOMY. Part V. Sect. XXI.

DIASTOLE, in grammar, a figure in proſody whereby a ſyllable naturally ſhort is made long. Such is the firſt ſyllable of *Priamides* in the following verſe of Virgil: *Atque hic Priamides! nihil o tibi amice, relictum.*

DIASURMUS, Διασυρμος, from δια, and συρω, *I draw*, in rhetoric, a figure whereby we ſhortly anſwer, or rather evade, a thing which it would be tedious to reply to in form.

E. gr. *What matters it to reply to an argument foreign to the purpoſe?*

DIATHESIS, from διατιθημι, *I diſpoſe*, a term uſed by ſome writers in the ſame ſenſe with conſtitution; and by others for a diſpoſition of the blood to a faulty ſtate.

DIATONIC, from δια, and τονος, *tone*, an epithet given to the common muſic, as it proceeds by tones, or degrees, both aſcending and deſcending. Authors divide the genera or kinds of muſic into *diatonic*, *chromatic*, and *enharmonic*. The *diatonic* genus was by the ancients divided into two ſpecies; the *molle*, and the *intenſum*. The laſt is in daily practice. It is commonly ſaid to conſiſt of two tones and a ſemi-tone: but, to ſpeak exactly, it conſiſts of a ſemi-tone major, a tone minor, and a tone major.

DIATRÆTA, a word uſed by Pliny, and others of the ancient Romans, to expreſs a ſort of cups and vaſes which were of great value, and only ſeen at the tables of the great. They were pellucid and colourleſs, and cut into various forms, and were often engraven upon with figures expreſſive of the deeds of honour of the family who poſſeſſed them.

DIATRAGACANTH, in pharmacy, is a name applied to certain powders, whereof gum tragacanth is the chief ingredient. There are two kinds, cold and hot.

DIAUGOPHRAGMIA, in natural hiſtory, a genus of foſſils of the order of ſeptariæ, whoſe partitions, or ſepta, conſiſt of ſpar with an admixture of cryſtal. Of this genus there are three ſpecies. 1. A red kind, with browniſh yellow partitions. 2. A browniſh yellow kind, with whitiſh partitions. 3. A bluiſh white kind, with ſtraw coloured partitions. Vide Hill, Hiſt. Foſſ. p. 522.

DICE, among gameſters, certain cubical pieces of bone or ivory, marked with dots on each of their faces, from one to ſix, according to the number of their ſides.

Sharpers have ſeveral ways of falſifying dice: 1. by ſticking a hog's briſtle into them, ſo as to make them run high or low as they pleaſe; 2. by drilling and loading them with quick-ſilver; which trick is diſcovered by holding them gently between two diagonal corners; when, if falſe, the heavy ſide will turn always downwards: 3. by filing and rounding them. But all theſe methods fall far ſhort of the arts of the dice makers, ſome of whom are ſo dextrous, that ſharping gameſters will have any money for ſuch dice. Dice pay a large ſtamp duty and are prohibited to be imported.

DICHOTOMY, *Biſection*, a term uſed by aſtronomers for that phaſis, or appearance of the moon, wherein ſhe is biſected, or ſhews juſt half her diſk, or circle; or when ſhe is in the beginning of her firſt and laſt quarter. The word is Greek, formed of διχοτομεω, *I beſect* or *cut into two*; of δις, *twice*, and τεμνω, *I cut*.

The time of the moon's dichotomy is of conſiderable uſe in fixing the ſun's diſtance from the earth. But it is very difficult to fix the preciſe moment when the moon is biſected, or in her true dichotomy.

DICHOTOMY, in botany, a term uſed to expreſs that diviſion of the branches which we ſee in miſletoe, and in the greater part of the ſea fucuſes, in which each branch is divided into two.

DICTAMNUS, white dittany, or fraxinella; a genus of the monogynia order, belonging to the decandria claſs of plants. There is only one ſpecies. It hath thick, penetrating, perennial roots, collected into a head at top, ſending up erect ſtalks annually, two or three feet high, garniſhed with pinnated alternate leaves, of three or four pair of oblong ſtiff lobes, terminated by an odd one; and the ſtalks crowned by long, pyramidal, looſe ſpikes of flowers, of white, red, and purple colours. They are very ornamental plants, and ſucceed in any of the common borders. See Syſtem of BOTANY, Sect. V. and Plate IV.

DICTATE, *Dictamen*, a ſuggeſtion, motion, or ſentiment of a man's conſcience. A good action becomes evil, if done contrary to the dictates of one's own conſcience.

DICTATE, *Dictata*, is likewiſe uſed in the ſchools for a leſſon, or exerciſe, wherein the maſter reading or ſpeaking ſomething the ſcholars take it down in writing after him. Here the act of the maſter is likewiſe called dictating.

DICTATOR, a Roman magiſtrate, created by the ſenate, or people, on ſome extraordinary and eminent occaſion, to command, with ſovereign authority, for a certain time, ordinarily limited to ſix months, though the office was ſometimes continued to twelve. Recourſe was never had to ſuch an officer but in dangerous and difficult times; as ſudden wars, popular factions, &c. He had abſolute and monarchic power while his dictature laſted: he was arbiter of peace and war, and had command of life and death, without any appeals lying to the people. Twenty four axes were borne before him, whereas only twelve before the conſuls. The origin of this office was unknown even in Livy's time: though ſome ancient authors ſpeak of T. Largius Flavius as the firſt dictator, who was appointed in the year of Rome 259. *Sed nec anno, nec quibus conſulibus—nec quis primum dictator creatus ſit, ſatis conſtat: apud veterrimos tamen auctores. T. Lartium dictatorem primum, Sp. Caſſium magiſtrum equitum creatos invenio. Conſulares legere.* Liv. lib. ii. Sylla was the firſt perpetual dictator, and Cæſar the next. After Cæſar, there were no more dictators. The firſt dictator choſen from among the people was Marcus Rutilius, in 399. Dioniſius Halicarnaſſius derives the word *ab edicendo*, becauſe they ordained or appointed what they pleaſed. But Varro will have the word taken hence, that the conſul named him, which the Latins call *dicere*, lib. iv. De Lingua Latina. Dictator *quod a conſule dicebatur cujus dicta audientes omnes eſſent.*

DICTION, the phraſe, elocution, or ſtyle of a writer, or ſpeaker. The diction or language of an orator ſhould be pure, proper to the ſubject, rich without affectation, ſtrong and cloſe without dryneſs, and ſuitable to the perſon, time, place, and audience. The diction of tragedy is accounted the fourth of the eſſential parts thereof: it is of the leaſt importance of any; yet muſt peculiar care be taken herein to make every paſſion ſpeak its proper language.

DICTIONARY, in its original acceptation, is the arranging all the words of a language according to the order of the alphabet, and annexing a definition or explanation to each word. When arts and ſciences began to be improved and extended, the multiplicity of technical terms rendered it neceſſary to compile dictionaries either of ſcience in general, or of particular ſciences, according to the views of the compiler.

Dictionaries of arts and ſciences were formerly conſidered uſeful only as works to refer to: but ſince the improved plan has been adopted of introducing complete Syſtems of the reſpective Sciences and diſtinct Treatiſes on all the principal arts; they have been eſteemed not only works of conſiderable uſe, but of great entertainment; becauſe they convey knowledge in a connected chain of deſcription, and thereby facilitate improvement, and contribute to amuſement, much more than can be done by treating on ſubjects in a detached and abſtracted manner.

Nor does the advantage reſt ſolely on this point, but extends in a greater degree beyond works on the old plan; as by referring for deſcription of technical words to the reſpective Syſtems and Treatiſes, a better idea muſt be formed in many inſtances of their ſignifications, applications and connections, than could be given of them in alphabetical order.

Another advantage reſulting from this new plan, is, that many authors may be employed at one and the ſame time in forming the various Syſtems and Treatiſes in their reſpective profeſſions, independent of the compiler, which cannot be the caſe on the old plan, where every article is ſubmitted to the arrangement and definition of an individual. By this means we have been and ſhall be enabled, during the courſe of this work, to call in the aſſiſtance of many literary characters, and by their joint efforts to give more accurate deſcriptions of Arts and Sciences than any work publiſhed in this kingdom.

Others have claimed the merit of purſuing the plan, which has raiſed the reputation of this work; that of retaining men of Science to form the ſeveral Syſtems and Treatiſes; but their pretences, independent of the compiler, are evidently groundleſs, as their reſpective productions have been anonymous; the only inference that can poſſibly be drawn from which is, that the Syſtems and Treatiſes are either the compilations of an individual, or that the parties concerned have been aſhamed to affix their ſignatures: whereas all our editors have avowed their productions, and may be referred to at their places of abode for the ſolution of any queſtion in the various Arts and Sciences they have undertaken to define.

The importance and utility of a Scientific Dictionary are evident from conſiderations of the higheſt moment, and particularly the following. It ſupplies in ſome degree the want of a large library, by furniſhing the curious and inquiſitive with Syſtems of Science that are diſperſed in many volumes, which cannot be procured without difficulty and conſiderable expence. It records and tranſmits to future ages many inventions and improvements which might otherwiſe ſink into oblivion. It forms a compendious hiſtory of Science, furniſhes the outlines of its gradual progreſs and advancement, and by preſerving a ſummary of what has been already done and diſcovered, lays a foundation for further diſcoveries and improvements.

A Dictionary of Science from this brief account of its deſign and uſe, muſt therefore be acknowledged a work of great conſequence; and its importance in every country will be eſtimated by the degree in which knowledge is purſued and promoted.

The labours and endeavours of men of curioſity, in all ages, have been chiefly confined to what are called, the Arts and Sciences. Their bounds have been enlarged from time to time, and new acquiſitions made from the adjoining waſte; but ſtill the ſpace of ground they poſſeſs is but narrow; and there is room either to extend them conſiderably, or to lay out new ones.

Art and Science are words of familiar uſe, and great ſignificance; yet, to aſcertain their meaning, requires ſome inveſtigation. To Science, ſeem to belong ſuch things as men may diſcover by the uſe of ſenſe and reaſoning; whatever the mind deſcries in virtue of that faculty whereby we perceive things, and their relations, is matter of ſcience: ſuch are the laws of nature, the affections of bodies, the rules and criterions of right and wrong, truth and error, the properties of lines and numbers, &c. Science, in effect, is the reſult of reaſon and ſenſe, in their general or natural ſtate, as imparted to all men, and not modified, or circumſtantiated, by any thing peculiar in the turn of a man's mind, the objects he has been converſant among, or the ideas preſented to him. In fine, ſcience is a ſeries of deductions, or concluſions, which every perſon, endued with thoſe faculties, may, with a proper degree of attention, ſee, and draw: and a ſcience, i. e. a formed ſcience, is no more than a ſyſtem of ſuch concluſions, relating to ſome one ſubject, orderly and artfully laid down in words.

To Art belong ſuch things as mere reaſon would not have attained to; things which lie out of the direct path of deduction, and which require a peculiar caſt, or turn of mind, to ſee, or arrive at. A man might call theſe the reſults of particular or perſonal reaſon, in oppoſition to the former; but that ſuch a denomination would be thought unphiloſophical. The difference between the two may be illuſtrated by that between wit and humour; the former whereof is a general faculty of exciting agreeable and ſurpriſing pictures in the imagination; and the latter a particular one: the former is pure and abſolute in its kind; the latter tinged with ſomething foreign and complexional.

An art and a ſcience, therefore, only ſeem to differ as leſs and more pure: a ſcience is a ſyſtem of deductions made by reaſon alone, undetermined by any thing foreign, or extrinſic to itſelf: an art, on the contrary, requires a number of data, and poſtulata, to be furniſhed from without; and never goes any length, without, at every turn, needing new ones. It is, in one ſenſe, the knowledge and perception of theſe data that conſtitutes the art: the reſt, that is, the doctrinal part, is of the nature of ſcience; which attentive reaſon alone will deſcry.

An art, in this light, appears to be a portion of ſcience, or general knowledge, conſidered, not in itſelf, as ſcience, but with relation to its circumſtances, or appendages. In a ſcience, the mind looks directly backwards and forwards to the premiſes and concluſions: in an art we alſo look laterally to the concomitant circumſtances. A ſcience, in effect, is that to an art, which a ſtream running in a direct channel, with regard to any thing but its own progreſs, is to the ſame ſtream turned out of its proper courſe, and diſpoſed into caſcades, jets, ciſterns, ponds, &c. In which caſe the progreſs of the ſtream is not conſidered with regard to itſelf, but only as it concerns the works; every one of which modifies the courſe of the ſtream, and leads it out of its way. It is eaſy to trace the progreſs of the former, from its riſe to its iſſue; becauſe its flows conſequentially: but a man ever ſo well acquainted with this, will not be able to diſcover that of the latter, becauſe it depends on the genius, humour, and caprice, of the engineer who laid the deſign.

The ultimate view of a Dictionary of Arts and Sciences ſhould be, the forming of a ſound mind, i. e. acquiring a ſyſtem of perceptions and notions agreeing to the ſyſtem of things, or in the relations thereto intended by its author. The end of learning and ſtudy, is not the filling of our heads with other men's ideas; that is an enrichment which may prove for the worſe: richneſs is only a matter of ſecondary conſideration; ſoundneſs is the firſt. There are many manures which the huſbandman dare not uſe, by reaſon they would corrupt the land, at the ſame time they enriched it, and lay the foundation of a diſeaſe, which would in the end impoveriſh, and make it ſpend itſelf in unprofitable weeds. But it muſt be owned, men's heads are not ſo eaſily filled; the memory is not ſo tenacious as we may imagine; ideas are tranſient things, and ſeldom ſtay long enough with us to do either much good, or harm: what we read to-day may be moſtly forgotten to-morrow. And what chiefly makes new ideas of any ſignificancy, is their extending and enlarging the mind, and making it more capacious, and ſuſceptible. But neither is this enlargement the laſt aim; but is chiefly of uſe, as it contributes to the increaſing our ſenſibility, to the making our faculties more ſubtile and adequate, and giving us a more exquiſite perception of things that occur; and thus enabling us to judge clearly, pronounce boldly, conclude readily, diſtinguiſh accurately, and apprehend the manner and reaſons of our deciſions.

DICTIONARY *of the Engliſh Language.* The only attempt which has hitherto been made towards forming a regular dictionary of the Engliſh language, is that of the learned Dr. Samuel Johnſon. But although it is executed in a maſterly manner, yet as it cannot be expected that an undertaking of this nature could be brought to perfection by one man, we ſhall venture to ſuggeſt a few circumſtances which, if duly attended to, may perhaps be of ſome utility.

The deſign of every dictionary of language, is to explain, in the moſt accurate manner, the meaning of every word; and to ſhow the various ways in which it can be combined with others, in as far as this tends to alter its meaning. The dictionary which does this in the moſt accurate manner, is the moſt complete. Therefore the principal ſtudy of a lexicographer ought to be, to diſcover a method which will be beſt adapted for that purpoſe. Dr. Johnſon, with great labour, has collected the various meanings of every word, and quoted the authorities: but, would it not have been an improvement if he had given an accurate definition of the preciſe meaning of every word; pointed out the way in which it ought to be employed with the greateſt propriety; ſhowed the various deviations from that original meaning, which cuſtom had ſo far eſtabliſhed as to render allowable; and fixed the preciſe limits beyond which it could not be employed without becoming a vicious expreſſion? With this view, it would have been neceſſary to exhibit the nice diſtinctions that take place between words which are nearly ſynonimous. Without this, many words can only be defined in ſuch a manner, as that they muſt be conſidered as exactly ſynonimous. We omit giving any quotations from Johnſon, to point out theſe defects; and ſhall content ourſelves with giving a few examples, to ſhow how, according to our idea, a dictionary of the Engliſh language ought to be compiled.

IMMEDIATELY, *adv. of time.*

1. Inſtantly, without delay. Always employed to denote future time, and never paſt. Thus, we may ſay, *I will come immediately*; but not, *I am immediately come from ſuch a place.* See PRESENTLY.

2. Without the intervention of any cauſe or event; as oppoſed to *mediately.*

PRESENTLY, *adv. of time.*

1. Inſtantly, without delay. Exactly ſynonimous with immediately; being never with propriety employed to denote any thing but future time.

2. Formerly it was employed to expreſs preſent time. Thus, *The houſe preſently poſſeſſed by ſuch a one,* was often uſed: but this is now become a vicious expreſſion; and we ought to ſay, *The houſe poſſeſſed at preſent.* It differs from *immediately* in this, that even in the moſt corrupt phraſes it never can denote paſt time.

FORM, *ſubſt.* The external appearance of any object, when conſidered only with reſpect to ſhape or figure. This term therefore, in the literal ſenſe, can only be applied to the objects of the ſight and touch; and is nearly ſynonimous with *figure*: but they differ in ſome reſpects. Form may be employed to denote more rude and unfiniſhed ſhapes; *figure*, thoſe which are more perfect and regular. Form can never be employed without denoting matter; whereas *figure* may be employed in the abſtract: thus, we ſay a ſquare or a triangle *figure*; but not a ſquare or triangular *form.* And in the ſame manner we ſay, the *figure* of a houſe; but we muſt denote the ſubſtance which forms that figure, if we uſe the word *form*; as, *a cloud of the form of a houſe,* &c. See FIGURE.

2. In contraſt to irregularity, or confuſion. As beauty cannot exiſt without order, it is, by a figure of ſpeech employed to denote beauty, order, &c.

3. As *form* reſpects only the external appearance of bodies, without regard to their internal qualities, it is, by a figure of ſpeech, employed in contraſt to theſe qualities, to denote empty ſhow, without eſſential qualities. In this ſenſe it is often taken when applied to religious ceremonies, &c.

4. As *form* is employed to denote the external appearance of bodies; ſo, in a figurative ſenſe, it is applied to reaſoning, denoting the particular mode or manner in which this is conducted; as, *the form of a ſyllogiſm,* &c.

5. In the ſame manner it is employed to denote the particular mode of procedure eſtabliſhed in courts of law; as, *the forms of law, religion,* &c.

6. *Form* is ſometimes, although improperly, uſed to denote the different circumſtances of the ſame body; as, *water in a fluid or a ſolid form.* But as this phraſe regards the internal qualities rather than the external figure, it is improper; and ought to be, *water in a fluid or a ſolid ſtate.*

7. But when bodies of different kinds are compared with one another, this term may be employed to denote other circumſtances than ſhape or figure: for we may ſay, *a juice exſuding from a tree in the form of wax or reſin*; although, in this caſe, the conſiſtence, colour, &c. and not the external arrangement of parts, conſtitutes the reſemblance.

8. From the regular appearance of a number of perſons arranged in one long ſeat, ſuch perſons ſo arranged are ſometimes called a *form*, as, *a form of ſtudents*, &c. And,

9. By an eaſy tranſition, the ſeat itſelf has alſo acquired that name.

GREAT, *adj.* A relative word, denoting largeneſs of quantity, number, &c. ſerving to augment the value of thoſe terms with which it is combined, and oppoſed to *ſmall* or *little*. The principal circumſtances in which this word can be employed, are the following:

1. When merely *inanimate* objects are conſidered with regard to quantity, *great* is with propriety employed, to denote that the quantity is conſiderable; as, *a great mountain*, *a great houſe*, &c. and it is here contraſted with *ſmall*. When *great* is thus employed, we have no other word that is exactly ſynonimous.

2. When *inanimate* objects are conſidered with regard to their extent, this term is ſometimes employed, although with leſs propriety; as, *a great plain*, *a great field*, &c. And in this ſenſe it is nearly ſynonimous with *large*; and they are often uſed indiſcriminately, but with ſome difference of meaning: for, as *large* is a term chiefly employed to denote extent of ſuperficies, and as *great* more particularly regards the quantity of matter; therefore, when *large* is applied to any object which is not merely ſuperficial, it denotes that it is the extent of ſurface that is there meant to be conſidered, without regard to the other dimenſions; whereas when the term *great* is employed, it has a reference to the whole contents. If, therefore, we ſay, *a large houſe* or *a large river*, we expreſs that the houſe, the river, have a ſurface of great extent, without having any neceſſary connection with the ſize in other reſpects. But if we ſay, *a great houſe*, or *a great river*, it at once denotes that they have not only a large ſurface, but are alſo of great ſize in every reſpect.

3. *Great*, when applied to the human ſpecies, never denotes the ſize or largeneſs of body, but is applied ſolely to the qualities of the mind. Thus, when we ſay, that *Socrates was a great man*, we do not mean that he was a man of great ſize, but that he was a man who excelled in the endowments of the mind. The terms which denote largeneſs of ſize in the human body are, *big*, *bulky*, *huge*, &c.

4. *Great* is ſometimes applied to the human ſpecies, as denoting high rank. In this caſe it is oftener uſed in the plural number than otherwiſe. Thus we ſay ſimply, *the great*, meaning the whole body of men in high ſtation, as oppoſed to *mean*. It ſhould ſeldom be employed in this ſenſe, as it tends to confound dignity of rank with elevation of mind.

5. As this is a general term of augmentation, it may be joined with all nouns which denote *quantity*, *quality*, *number*, *excellence*, or *defects*; or ſuch as imply *praiſe*, *blame*, *anger*, *contempt*, or any other affection of the mind.

6. It is employed to denote every ſtep of aſcending or deſcending conſanguinity; as, *great grandfather*, *great grandſon*, &c.

Theſe examples may ſerve to give ſome idea of the plan of an Engliſh Dictionary compoſed upon philoſophical principles: But, beſides the circumſtances above enumerated, there are many others which would require particular attention in the execution of a work of this kind. In the Engliſh language, a great variety of terms occur, which denote matter under certain general forms or circumſtances, without regarding the minute diverſities that may take place; as the word *cloth*, which denotes matter as manufactured into a particular form, including under it all the variety of ſtuffs manufactured in that particular way, of whatever materials, colours, texture, or fineneſs, they may be. The ſame may be ſaid of *wood*, *iron*, *yarn*, and a great variety of terms of the ſame nature, ſome of which cannot aſſume any plural; while others admit of it in all caſes, and others admit or refuſe it according to the different circumſtances in which they are conſidered. In a dictionary, therefore, all this variety of caſes ought to be clearly and diſtinctly pointed out under each particular article; this is the more neceſſary, as ſome of theſe words have others formed from them, which might be readily miſtaken for their plurals, although they have a very different ſignification: as *cloaths*, which does not denote any number of pieces or different kinds of *cloth*, but *wearing apparel*. The following example will illuſtrate this head.

WOOD, *ſub.* A ſolid ſubſtance, of which the trunks and branches of trees conſiſt.

1. The term is employed to denote the ſolid parts of vegetables of all kinds, in whatever form or circumſtances they are found. Nor does this term admit of plural with propriety, unleſs in the circumſtances after-mentioned: for we ſay, *many different kinds of wood*, in preference to *many kinds of woods*; or, as we ſay, *oak*, *aſh*, or *elm wood*, not *woods*.

2. But where we want to contraſt *wood* of one quality or country with that of another, it admits of a plural: for we ſay, *white woods are in general ſofter than red*; or *Weſt-Indian woods are in general of greater ſpecific gravity than the European woods*: But unleſs where the colour, or ſome quality which diſtinguiſhes it from growing wood, is mentioned, this plural ought as much as poſſible to be avoided, as it always ſuggeſts an idea of growing wood.

3. *Wood* likewiſe denotes a number of trees growing near one another: being nearly ſynonimous with *foreſt*: See Forest. In this ſenſe it always admits of a plural; as, *Ye woods, and wilds, whoſe ſolitary gloom*, &c.

As the Engliſh language is ſo exceedingly irregular in the pronunciation, the ſame letter in the ſame ſituation often aſſuming ſounds totally different in different words, it is impoſſible to eſtabliſh any general rules on this ſubject, which do not admit of many exceptions; therefore, a dictionary is the beſt means of aſcertaining and pointing out the proper pronunciation of words. For, if the writer firſt pointed out all the different ſounds that the ſame letter could ever be made to expreſs, and aſſigned to every particular ſound which each letter could be made to aſſume, a particular mark, which was appropriated to denote that particular ſound of the letter whenever it occurred; by placing theſe particular marks above the letters in the dictionary, the ſound of each letter would be pointed out in all caſes with the utmoſt certainty. It would be impoſſible for us to illuſtrate this by examples, without firſt aſcertaining all the ſounds of each letter; which would lead us into a diſcuſſion too long for this place; and this is at preſent the more unneceſſary, as the public have been long in expectation of a dictionary, by a very able hand, in which this particular will be attended to.

We ſhall only further obſerve, that, beſides having the accented ſyllable of every word *properly* diſtinguiſhed in a dictionary to aſſiſt in the pronunciation, the Engliſh language requires another eſſential improvement, *viz.* the uſe of accents to diſtinguiſh the meaning of *words* and *phraſes*; which, although it is not ſo properly confined to a lexicographer, yet it is not quite without his ſphere. Thus the word *as* admits of two very different ſounds, as well as different ſignifications: as in this example, "Cicero was nearly *as* eloquent *as* Demoſthenes:" in which the firſt *as* is pronounced *aſs*, and the laſt is pronounced *az*. Now, it often happens, that, in reading, the particular way in which it ought to be underſtood is not pointed out by the context, till after the word itſelf is pronounced, which has an equal chance at leaſt of being pronounced wrong; whereas, if it were always accented when employed in the one ſenſe, and not in the other, it would free the reader from this perplexity. There are other caſes in which the uſe of proper accents in writing would be of great conſequence; as at the beginning of a ſentence, when it was put as a queſtion, or uſed ironically, &c. the want of which every one muſt have obſerved. But as this does not ſo properly belong to the lexicographer as the grammarian, we ſhall here take no further notice of it.

The above examples, we hope, will be ſufficient to give the reader ſome idea of the plan that we would propoſe; and enable him to determine, whether or not a dictionary, executed upon this plan, would convey to his mind a more perfect knowledge of the Engliſh language, than thoſe dictionaries that have been hitherto publiſhed. Theſe examples were given rather with a view to ſhow the manner in which a work of this kind might be conducted, than as perfect and unexceptionable explanations of the ſeveral articles there enumerated; and therefore we did not think it neceſſary to produce any authorities, although we are ſenſible that they would be requiſite in a work of this kind.

DIDACTIC, ſignifies the manner of ſpeaking, or writing, adapted to teach or explain the nature of things. The word is formed from the Greek διδασκω, *doceo*, *I teach*. There are many words that are only uſed in the *didactic*, and dogmatic way: and there are many works, ancient and modern, both in proſe and verſe, written after this method; ſuch are the Georgics of Virgil, Lucretius's poem De Rerum Natura, and Pope's Eſſays on Criticiſm, and on Man, &c.

DIDELPHIS, or Oppossum, in tetrapodology; a genus of quadrupeds belonging to the order of feræ, the characters of which are theſe: they have ten fore-teeth in the upper jaw, and eight in the under one. The dog-teeth are long; the tongue is ſomewhat ciliated; and they have a pocket formed by a duplicature of the ſkin of the belly, in which the dugs are included. The tail of this animal has a diſagreeable appearance, looking like the body of a ſnake, and has the ſame prehenſile quality with that of ſome monkeys; the body is round and pretty thick, the legs ſhort: on the lower part of the belly of the female is a large pouch, in which the teats are lodged, and where the young ſhelter as ſoon as they are born. The length of the body is 16 or 17 inches; that of the tail 14. This creature inhabits many parts of America and the Eaſt Indies. It is very deſtructive to poultry, and ſucks the blood without eating the fleſh; it feeds alſo on roots and wild fruits, and is very active in climbing trees. It hunts eagerly after birds and their neſts; and will hang ſuſpended from the branches of a tree by its tail; then, by ſwinging its body, it will fling itſelf among the trees that grow in the neighbourhood. It walks very ſlow; and when purſued and overtaken, will feign itſelf dead. It is not eaſily killed, being as tenacious of life as a cat. When the female is about to bring forth, ſhe makes a thick neſt of dry graſs in ſome cloſe buſh at the foot of a tree: and brings four, five, or ſix, young at a time. As ſoon as the young are brought forth, they take ſhelter in the pouch or falſe belly; and faſten ſo cloſely to the teats, that they cannot be ſeparated without difficulty. They are blind, naked, and very ſmall, when new-born, and reſemble fetuſes: it is therefore neceſſary that they ſhould continue in that falſe-belly, till they attain proper ſtrength and ſight; and are prepared to undergo what may be called a *ſecond birth*. After this they run into the pouch as into an aſylum in time of danger; and the parent carries them about with her. During the time of this ſecond geſtation, the female ſhews an exceſſive attachment to her young, and will ſuffer any torture rather than allow this receptacle to be opened; for ſhe has the power of opening or cloſing it by the aſſiſtance of ſome very ſtrong muſcles. The fleſh of the old animal is very good, like that of a ſucking pig: the hair is dyed by the Indian women, and wove into garters and girdles; the ſkin is very fetid.

2. The Murina. 3. The Maxican Opoſſum. 4. The ſhort tailed Opoſſum. 5. The Opoſſum of Surinam. 6. The Dorſigera or Merian Opoſſum.

DIDYNAMIA, in botany, the fourteenth claſs of plants, whoſe flowers have two of their male parts or ſtamina of greater efficacy in the action of impregnation of the ſeeds than the other two: they are known by the efficacious ſtamina being always much longer than the others. The word is formed of the Greek δις, *twice*, and δυναμις, *power* or *efficacy*. Of this claſs of plants are baum, thyme, lavender, baſil. See Syſtem of BOTANY, Sect. V. and Plate V.

DIESIS, from διεμι, *I divide*, in muſic, a diviſion of a tone, leſſer than a ſemitone; or an interval conſiſting of a leſſer, or imperfect ſemitone.

DIESPITER, in antiquity, a name given to Jupiter.

DIET, in medicine, according to ſome, comprehends the whole regimen, or rule of life, with regard to the ſix non-naturals; air, meats, and drinks, ſleep, and watching, motion and reſt, paſſions of the mind, retentions and excretions. Others reſtrain the term of diet, to what regards eating and drinking, or ſolid aliments and drinks. The word is formed from the Greek διαιτα, which ſignifies *regimen*, or *rule of life*, preſcribed by phyſicians. See Syſtem of MEDICINE.

DIET *Drinks*, a form of phyſic, including all the medicated wines, wheys, and ales, uſed in chronic caſes. They require a courſe or continuance to anſwer any intention of moment. In acute caſes they are of no uſe; but where the diſorder of a conſtitution is gradually to be gained upon, much help may be had from them.

DIET, or DYET, an aſſembly of the ſtates or circles of the empire of Poland, to deliberate and concert meaſures for the public good. The general diet of the empire is ordinarily held at Ratiſbon. It conſiſts of the emperor in perſon, or by his repreſentative or commiſſary; the nine electors, three of whom are eccleſiaſtics, and the other ſix ſecular, forming the electoral college: the eccleſiaſtical princes, viz. archbiſhops, biſhops, abbots, and abbeſſes, and the ſecular princes, forming the ſecond college; and the repreſentatives of the imperial cities, who conſtitute the third college, and are divided into two benches, viz. that of Suabia and of the Rhine. This diet has been uſually ſummoned by the emperor, but there are ſome caſes in which the electors have ſummoned it without his conſent, or requeſted him to ſummon it. In the abſence of the emperor, the right of convocation belongs to the king of the Romans. The diet makes laws, raiſes taxes, determines differences between the ſeveral princes and ſtates, and relieves the ſubjects from the oppreſſions of their ſovereigns. The diets of the empire were originally the ſame with the aſſemblies of March and May, held by the kings of France: they met at leaſt once a year; and every freeman had a right to be preſent. Theſe were aſſemblies, in which the monarch deliberated with his ſubjects, concerning their common intereſt: but when the princes, dignified eccleſiaſtics, and barons, acquired territorial and independent juriſdiction, the diet became an aſſembly of the ſeparate ſtates, which formed an union, of which the emperor was the head. Robertſon's Hiſt. Charles V. vol. i. p. 462.

The term diet is alſo applied to the aſſembly of electors for the choice of an emperor or king of the Romans: this is uſually held at Frankfort on the Main. The general diet of Poland is by the laws only to be held every two years; but preſſing occaſions convene them every year.

There are likewiſe diets held at Switzerland; diets of the proteſtant cantons; diets of the catholic cantons; and general diets. The firſt aſſemble at Araw, and are convoked by the canton of Zurich; the ſecond at Lucern, convoked by the canton of that name; the third, compoſed of the deputies of all the cantons, both proteſtant and catholic, is held twice a year, at the end of June, and the beginning of December, and meets at Baden. It is the canton of Zurich which has the right of convening it.

DIEU *et mon droit*, q. d. *God and my right*, the motto of the arms of England, firſt given by king Richard I. to intimate, that he held not his empire in vaſſalage of any mortal. It was afterwards taken up by Edward III. when he firſt claimed the crown of France; and it was continued, without interruption, to the time of king William III. who uſed the motio *Je maintiendray*; though he commanded the former to be retained on the great ſeal. The ſame is to be underſtood of the late queen Anne, who uſed the motto, *Semper eadem*; which had been before uſed by queen Elizabeth. But ever ſince queen Anne, *Dieu et mon droit* continues to be the royal motto.

DIEXAHÆDRIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek δις, *twice*, εξ, *ſix*, and εδρα, *ſide*. The bodies of this genus are ſpars, compoſed of twice ſix planes, being formed of two hexædral pyramids, joined baſe to baſe, without any intermediate column. Of this genus there are only two known ſpecies: 1. One with long, narrow, and ſharp pointed pyramids, found in Lamb's cave, on Mendip hills: and, 2. One with long, broad, and obtuſe pyramids: this is found in the mine of Goſſelar in Saxony, and in many of the mines of the Hartz Foreſt. Hill's Hiſt. of Foſſils, p. 213.

DIFFERENCE, in logic, an eſſential attribute belonging to ſome ſpecies, and not found in the genus; being the idea that defines the ſpecies.

Thus, body and ſpirit are the two ſpecies of ſubſtance, which in their ideas include ſomething more than is included in the idea of ſubſtance. In body, for inſtance, is found impenetrability, and extenſion; in ſpirit, a power of thinking, and reaſoning: ſo that the difference of body is impenetrable extenſion, and the difference of ſpirit is cogitation.

DIFFERENCE, in mathematics, the exceſs of one quantity above another. When a leſs quantity is ſubtracted from a greater, what remains is called the difference.

DIFFERENCES, in heraldry, certain additaments to coat-armour; whereby ſomething is altered, or added, to diſtinguiſh the younger families from the elder, or to ſhew how far they are removed from the principal houſe. They are called in Latin, *diminutiones*, and *diſcernicula armorum*; and by the French, *briſures*.

DIFFERENTIAL, *Differentiale*, in the higher geometry, an infinitely ſmall quantity, or a particle of quantity ſo ſmall as to be leſs than any aſſignable one. It is called a differential, or differential quantity, becauſe frequently conſidered as the difference of two quantities; and, as ſuch, it is the foundation of the differential calculus. Sir Iſaac Newton, and the Engliſh, call it a moment, as being conſidered, as the momentary increaſe of quantity. See FLUXIONS.

DIFFERENTIAL *Method*, in mathematics, an appellation given to a method of deſcribing a curve of the parabolic kind through any given number of points. See Syſtem of GEOMETRY.

DIFFRACTION, in optics, a term firſt uſed by Grimaldi the jeſuit, to denote that property of the rays of light, which others have called inflection; the diſcovery of which ſome attribute to Grimaldi, and others to Dr. Hooke.

DIFFUSE, an epithet applied to ſuch writings as are wrote in a prolix manner. Among hiſtorians, Salluſt is reckoned ſententious, and Livy diffuſe. Thus alſo among the orators, Demoſthenes is cloſe and conciſe; Cicero, on the other hand, is diffuſe.

DIFFUSION, from *diffundo*, *I pour out*, *I dilate*, the act whereby a body is ſpread, or ſtretched out, ſo as to take up more ſpace. The learned make three kinds of diffuſion: the firſt, that whereby a pure quality is diffuſed; as cold, force, &c. This they diſtinguiſh into equal, whereby equal portions, or degrees, of the quality are diſtributed upon equal parts of the medium; thus, when a direct motion is impreſſed on a moveable, all the parts of the moveable receive an equal impetus; and unequal, when unequal degrees of the quality, are diſtributed on different parts of the ſubject: thus it is, that force is impreſſed on a lever, and cold propagated through a medium. The ſecond kind of diffuſion is that performed by the motion of bodies; ſuch is the diffuſion of light, ſound, ſmell, magnetic, electric virtues, &c. The third is performed partly by the motion of corpuſcles, and partly by the diffuſion of a quality; and thus they hold fire to be diffuſed.

But the modern philoſophers reject the notion of qualities, and their diffuſion. According to them, there is no other diffuſion, but that of corporeal ſubſtance, emitted in minute effluvia, or particles, into a kind of atmoſphere all around the body; which diffuſion of corpuſcles ſome call atmoſpherical, as being ſuppoſed to be terminated by a circle, whereof the diffuſing body is the centre. Every body, it is now proved, has its ſphere of activity, or diffuſion, within which the particles, or corpuſcles, torn from it, and flying away, have a ſenſible effect; as we ſee in odorous, ſonorous, &c. bodies. See QUALITY, where the phyſical law of the diffuſion of qualities is laid down.

DIGASTRICUS, in anatomy, a muſcle of the lower jaw, thus called, as having a double belly. See Syſtem of ANATOMY, Part III. Sect. II.

DIGEST, methodical diſtribution or arrangement of any literary, a ſcientific ſubject.

DIGEST, *Digeſtum*, a collection of the Roman laws, ranged and digeſted under proper titles, by order of the emperor Juſtinian. That prince gave his chancellor Tribonianus a commiſſion for this purpoſe; who, in conſequence thereof, choſe ſixteen juriſconſulti, or lawyers, to work upon the ſame. Theſe, accordingly, took out the beſt and fineſt deciſions from the two thouſand volumes of the ancient juriſconſulti, and reduced them all into one body; which was publiſhed in the year 533, under the name of the digeſt. To this the emperor gave the force of a law, by a letter at the head of the work, which ſerves it as a preface. The digeſt makes the firſt part of the Roman law, and the firſt volume of the corpus, or body of the civil law, contained in fifty books. It was tranſlated into Greek under the ſame emperor, and called Pandecta.

Cujas ſays, that digeſt is a common name for all books diſpoſed in a good order and œconomy; and hence it is, that Tertullian calls the goſpel of St. Luke, a digeſt. Hence alſo abridgments of the common law are denominated digeſts of the numerous caſes, arguments, readings, pleadings, &c. diſperſed in the year-books, and other reports of the books of the law, reduced under proper heads, or common places. The firſt was that of Statham, which comes as low as Henry VI. That of Fitzherbert was publiſhed in 1516; Brook's in 1573, or which Hughes's, publiſhed in 1663, in a ſequel. Rolls, Danvers, and Nelſon, have alſo publiſhed digeſts or abridgments of this kind, including the caſes of later days; to which may be added the New Abridgement, and Viner's Abridgement.

DIGESTION, in medicine, that change of the food, taken in at the mouth, which it undergoes in the ſtomach, in order to afford fit matter to compoſe, or increaſe, an animal, till it arrives at its deſtined bulk; and to repair the loſs of thoſe particles which the body, in its natural ſtate, neceſſarily undergoes. The operation of digeſtion ſucceeds to maſtication, and deglutition. It includes chylification, and is ſucceeded by ſanguification, and nutrition.

Mr. John Hunter who has made ſeveral experiments on the digeſtion of the ſtomach after death; having obſerved that animals, or parts of animals, poſſeſſed of the living principle, when taken into the ſtomach, are not in the leaſt affected by the powers of that viſcus, whilſt the living principle remains; he ſhews, that the ſtomach when deprived of the living principle, is itſelf capable of being digeſted either by the digeſtive powers of other ſtomachs, or by the remains of that power which it had of digeſting other things. And hence it happens, that the ſtomachs of dead bodies are found diſſolved at their greater extremity, from their own natural digeſtive powers, and not in conſequence of any diſeaſe; appearances of this kind being moſt frequent in thoſe that have died violent deaths. This digeſtive power of the ſtomach was farther evinced in fiſh, which ſwallow their food whole, and ſwallow fiſh much larger than the digeſting part of the ſtomach can contain: the part lodged in the ſtomach was found more or leſs diſſolved, whilſt the part left in the œſophagus remained perfectly ſound; and the digeſting part of the ſtomach was itſelf, in many caſes, actually diſſolved.

From ſeveral facts of this kind, Mr. Hunter inferred, that the ſtomach, being dead, was no longer capable of reſiſting the power of that menſtruum, which itſelf had formed for the digeſtion of its contents; and that digeſtion is performed not by any mechanical power, nor contractions of the ſtomach or heart, but by ſomething ſecreted in the coats of the ſtomach, which is thrown into its cavity, and here animalizes the food, or aſſimilates it to the nature of the blood. Mr. Hunter has found in the ſtomachs of all animals, to which his obſervations or experiments have extended, an acid, but not a ſtrong one, in the juices contained in that viſcus in a natural ſtate. Phil. Tranſ. vol. lxii. art. 32. p. 447, &c. For a further account of this ſubject, ſee Syſtem of Anatomy, Sect. XIII.

Digestion, in chymiſtry, is a preparation of plants, minerals, metals, or other bodies, by putting them, with ſome proper fluid, in a veſſel, and heating them gradually over a gentle fire, like the heat of an animal body. Digeſtion is ordinarily confounded with maceration: but the two things differ, in that there is heat required to digeſtion; whereas maceration is done in the cold. Digeſtion is uſually performed with the addition of ſome menſtruum ſuitable to the matter: thus roſes and poppies heads are put to digeſt in oil, or water, to make unguents, and ſyrups; calcined lead, and ceruſs, are digeſted in diſtilled vinegar, to make the magiſtery thereof, or the ſal ſaturni. Hence Dr. Friend defines digeſtion to be the ſolution of bodies, made by menſtruums with the aſſiſtance of fire. The uſe of digeſtion in pharmacy, is to extract the more volatile particles, and mix them intimately with the menſtruum. Another great uſe of digeſtion is the duly preparing of the eſſence of mineral ſulphurs; the ſtony ſea-plants, which greatly reſemble the nature of foſſils, are alſo better treated by this proceſs than by any other. Tartariſed ſpirits of wine, receives a very high tincture from red coral, after a long digeſtion, in any diſtilled vegetable oil, though it will not in the common way be all at coloured by it. Phil. Tranſ. N° 87.

Digestion, in ſurgery, expreſſes a diſpoſition in abſceſſes to ripen and come to ſuppuration. Tumors, ariſing on the parotides of children, are of eaſy digeſtion: they ripen in a little time.

DIGESTIVE is alſo uſed, in medicine, for ſuch remedies as ſtrengthen and increaſe the tone of the ſtomach, and aſſiſt in the digeſtion of foods. To this claſs belong all ſtomachics and ſtrengtheners, or corroborants.

Digestive, in ſurgery, denotes a ſort of unguent, plaſter, or the like, that ripens and prepares the matter of wounds, &c. for ſuppuration. The common digeſtive is compoſed of turpentine, yolk of eggs, oil of St. John's wort, unguentum buſilicum, and tincture of aloes.

DIGGING, in mineralogy, a term appropriated by the miners to expreſs that penetrating into the earth, where they have the ore, before them, and every ſtroke of the tools turns to account. They appropriated the word to this ſenſe, expreſſing the random openings, which they make in ſearch of mines, by the word *hatching*, or *eſſay-hatching*.

DIGIT, in aſtronomy, is the meaſure whereby we eſtimate eclipſes: amounting to the twelfth part of the diameter of the luminary eclipſed. The diameter of the body, or diſk, of the ſun or moon, is divided into twelve parts, called *digits*; and an eclipſe is ſaid to be of ten *digits*, when ten of thoſe parts are hid.

Digit, in arithmetic, ſignifies an integer, or number, under ten; as 1, 2, 3, 4, 5, 6, 7, 8, 9.

Digit is alſo a meaſure taken from the breadth of the finger. A digit is properly three-fourths of an inch, and equivalent to four grains of barley, laid breadth-wiſe, ſo as to touch each other.

DIGITALIS, fox glove, a genus of the angioſpermia order, belonging to the didynamia claſs of plants. There are ſix ſpecies, five of which are hardy, herbaceous, biennial and perennial plants, and the ſixth a tender, ſhrubby exotic. See Syſtem of Botany, Plate V.

DIGITATED *Leaf*, among botaniſts. See Syſtem of Botany, Sect. IV. Plate I. *Fig.* 66.

DIGLYPH, from δις, *twice*, and γλυφω, *I engrave*, a kind of imperfect triglyph, conſole, or the like, with only two channels, or engravings, inſtead of three. See Triglyph.

DIGNITARY, in the canon law, a perſon who holds a dignity, that is a benefice which gives him ſome pre-eminence, above mere prieſts and canons. Such is a biſhop, dean, archdeacon, prebendary, &c.

DIGNITY, in its moſt uſual acceptation, ſignifies honour and authority, reputation, &c. and dignity may be divided into ſuperior and inferior; as the titles of duke, earl, baron, &c. are the higheſt names of dignity; and thoſe of baronet, knight, ſerjeant at law, &c. the loweſt. Nobility only can give ſo high a name of dignity, as to ſupply the want of a ſurname in legal proceedings; and as the omiſſion of a name of dignity may be pleaded in abatement of a writ, &c. ſo it may be where a peer who has more than one name of dignity, is not named by the moſt noble. 2 Hawk. P. C. 185, 230. No temporal dignity of any foreign nation can give a man a higher title than that of eſquire. 2 Inſt. 667.

Dignity, in the human character, the oppoſite of meanneſs. Man is endued with a ſenſe of the worth and excellence of his nature: he deems it more perfect than that of the other beings around him; and he perceives that the perfection of his nature conſiſts in the virtues of univerſal benevolence. To expreſs that ſenſe, the term dignity is appropriated. Further, to behave with dignity, and to refrain from all mean actions, is felt to be, not a virtue only, but a duty: it is a duty every man owes to himſelf. By acting in that manner, he attracts love and eſteem: by acting meanly, or below himſelf, he is diſapproved and contemned. This ſenſe of the dignity of human nature, reaches even our pleaſures and amuſements. If they enlarge the mind by raiſing grand or elevated emotions, or if they humanize the mind by exerciſing our ſympathy, they are approved as ſuited to the dignity of our nature: if they contract the mind by fixing it on trivial objects, they are contemned as not ſuited to the dignity of our nature.

This leads us to examine more directly emotions and paſſions with reſpect to the preſent ſubject: and it will not be difficult to form a ſcale of them, beginning with the meaneſt, and aſcending gradually to thoſe of the higheſt rank and dignity. Pleaſure felt as at the organ of ſenſe, named corporeal pleaſure, is perceived to be low; and when indulged to exceſs, is perceived alſo to be mean: for that reaſon, perſons of any delicacy diſſemble the pleaſure they take in eating and drinking. The pleaſures of the eye and ear, having no organic feeling, and being free from any ſenſe of meanneſs, are indulged without any ſhame: they even riſe to a certain degree of dignity when their objects are grand or elevated. Sympathetic diſtreſs is never mean: on the contrary, it is agreeable to the nature of a ſocial being, and has general approbation. The rank that love poſſeſſes in the ſcale, depends in a great meaſure on its object; it poſſeſſes a low place when founded on external properties merely; and is mean when beſtowed on a perſon of inferior rank without any extraordinary qualification: but when founded on the more elevated internal properties, it aſſumes a conſiderable degree of dignity. The ſame is the caſe of friendſhip. When gratitude is warm, it animates the mind; but it ſcarce riſes to dignity. Joy beſtows dignity when it proceeds from an elevated cauſe.

Revenge, though it enflame and ſwell the mind, is not accompanied with dignity, not even with elevation: it is not however felt as mean or groveling, unleſs when it takes indirect meaſures for gratification. Shame and remorſe, though they ſink the ſpirits, are not mean. Pride, a diſagreeable paſſion, beſtows no dignity in the eye of a ſpectator. Vanity always appears mean; and extremely ſo where founded, as commonly happens, on trivial qualifications.

We proceed to the pleaſures of the underſtanding, which poſſeſs a high rank in point of dignity. Of this every one will be ſenſible, when he conſiders the important truths that have been laid open by ſcience; ſuch as general theorems, and the general laws that govern the material and moral worlds. The pleaſures of the underſtanding are ſuited to man as a rational and contemplative being, and they tend not a little to ennoble his nature; even to the Deity he ſtretcheth his contemplations, which in the diſcovery of infinite power, wiſdom, and benevolence, afford delight of the moſt exalted kind. Hence it appears, that the fine arts, ſtudied as a rational ſcience, afford entertainment of great dignity; ſuperior far to what they afford as a ſubject of taſte merely.

But contemplation, however in itſelf valuable, is chiefly reſpected as ſubſervient to action; for man is intended to be more an active than a contemplative being. He accordingly ſhows more dignity in action than in contemplation: generoſity, magnanimity, heroiſm, raiſe his character to the higheſt pitch: theſe beſt expreſs the dignity of his nature, and advance him nearer to divinity than any other of his attributes.

Having endeavoured to aſſign the efficient cauſe of dignity and meanneſs, by unfolding the principle on which they are founded, we proceed to explain the final cauſe of dignity or meanneſs beſtowed upon the ſeveral particulars above-mentioned, beginning with corporeal pleaſures. Theſe, as far as uſeful, are, like juſtice, fenced with ſufficient ſanctions to prevent their being neglected: hunger and thirſt are painful ſenſations; and we are incited to animal love by a vigorous propenſity: were corporeal pleaſures dignified over and above with a place in a high claſs, they would infallibly overturn the balance of the mind, by outweighing the ſocial affections.

The more refined pleaſures of external ſenſe, conveyed by the eye and the ear from natural objects and from the fine arts, deſerve a high place in our eſteem, becauſe of their ſingular and extenſive utility: in ſome caſes they riſe to a conſiderable dignity: and the very loweſt pleaſures of the kind are never eſteemed mean or groveling. Pleaſures ariſing from wit, humour, ridicule, or from what is ſimply ludicrous, is uſeful, by relaxing the mind after the fatigue of more manly occupation: but the mind, when it ſurrenders itſelf to pleaſure of that kind, loſes its vigour, and ſinks gradually into ſloth. As all valuable improvements proceed from the exerciſe of our rational faculties, the author of our nature, in order to excite us to a due uſe of theſe faculties, hath aſſigned a high rank to the pleaſures of the underſtanding: their utility, with reſpect to this life as well as a future, intitles them to that rank.

But as action is the aim of all our improvements, virtuous actions juſtly poſſeſs the higheſt of all the ranks. Theſe, we find, are by nature diſtributed into different claſſes, and the firſt in point of dignity aſſigned to actions that appear not the firſt in point of uſe: generoſity, for example, in the ſenſe of mankind is more reſpected than juſtice, though the latter is undoubtedly more eſſential to ſociety; and magnanimity, heroiſm, undaunted courage, riſe ſtill higher in our eſteem.

Dignity, in oratory, is one of the three parts of general elocution, and conſiſts in the right uſe of tropes and figures.

DIGRESSION, in oratory, is defined by Quintilian, agreeably to the etymology of the word, to be a going off from the ſubject we are upon to ſome different thing, which, however, may be of ſervice to it. Inſt. Or. lib. iv. cap. 3.

Digreſſion is not a neceſſary part of a diſcourſe, though it may ſometimes be convenient on ſeveral accounts; as were a ſubject is of itſelf flat and dry, and requires cloſe attention; in this caſe it is of uſe to relieve the mind by ſomething agreeable and entertaining. But as it ſhould never be introduced without ſufficient reaſon, it ſhould never be too frequent, nor too long. Ward's Or. vol. i. p. 283. &c.

DIGYNIA, in the Linnæan ſyſtem of botany, the ſecond order of the 8th claſs of plants, called oxtandria. The term is derived from δις, *double*, and γυνη, *wife*. See Syſtem of Botany. Sect. V. Plate IV.

DIJAMBUS, in poetry, the foot of a Latin verſe of four ſyllables; it is compounded of two iambics, as *ſĕvērĭtās*.

DIKE, a ditch, or drain, made for the paſſage of waters. The word ſeems formed from the verb, *to dig*; though others chooſe to derive it from the Dutch, *diik*, a *dam*, *ſea bank*, or *wall*.

Dike, or **Dyke**, alſo denotes a work of ſtone, timber, or faſcines, raiſed to oppoſe the entrance, or paſſage of the waters of the ſea, a river, lake, or the like. The word comes from the Flemiſh *dyk*, or *diik*, a heap of earth to bound or ſtem the water. Junius and Menage, take the Flemiſh to have borrowed their word from the Greek τειχος, *wall*. Guichard derives it from the Hebrew *daghah*. Theſe dikes are uſually elevations of earth, with hurdles or ſtakes, ſtones, and other matters. The dike of Rochelle is made with veſſels faſtened to the bottom. The dikes of Holland are frequently broke through, and large tracts of land are then drowned.

DILAPIDATION, a waſteful deſtroying, or letting buildings run to ruin and decay, for want of neceſſary reparation. An action lies for dilapidations, either in the ſpiritual court by the canon law, or in the courts of common law; and it may be brought by the ſucceſſor againſt the predeceſſor, if living, or, if dead, againſt his executors. The money recovered for dilapidation, by 14 Eliz. 11, muſt be employed in the repair of the ſame houſes, within two years, on penalty of forfeiting double the value to the crown.

DILATATION, in phyſics, a motion of the parts of a body, whereby it expands or opens itſelf ſo as to occupy a greater ſpace. The generality of authors confound dilatation with rarefaction; but the more accurate, diſtinguiſh between them; defining dilatation to be the expanſion of a body, into a greater bulk, by its own elaſtic power; and rarefaction, the like expanſion produced by means of heat.

Dilatation, in ſurgery, denotes the laying open any orifice, or the lips of a wound, wider; or the extenſion of any veſſel, or the like. This is done by an inſtrument called a dilatatorium.

DILATATOR *Poſticus Urethræ*, in anatomy, a name given by Heiſter, and ſome others, to what is ſuppoſed to be a peculiar muſcle by many, and called alſo *levator ſextus ani*, and by ſome other names, though it is really only a proceſs of the ſphincter ani running into the perinæum.

DILATATORES *Alæ Naſi*, called alſo *Rinæi Naſales*, in anatomy, a pair of muſcles common to the *alæ naſi*, and upper lip. They ariſe thin, broad, and fleſhy, from the cheek bones under the orbits of the eyes, and deſcend obliquely with a two fold order of fleſhy fibres in each muſcle; which partly terminate in the upper lip, and partly in the *alæ naſi*. They draw the *alæ* from each other, and widen the external openings of the noſtrils. See Syſtem of Anatomy, Sect. IX.

DILATORY *Pleas*, in law, are ſuch as are put in merely for delay; and there may be a demurrer to a dilatory plea, or the defendant ſhall be ordered to plead better, &c. 6 Mod. The truth of dilatory pleas is to be made out by affidavit of the fact, &c. by ſtat. 4 and 5 Anne.

DILEMMA, Διλεμμα, in logic, an argument conſiſting of two, or more propoſitions, ſo diſpoſed, that grant which you will of them, you will be preſſed by the concluſion. The word is from the Greek δις, *bis*, *twice*, and λεμμα, *ſumptio*.

DILL, anethum, in botany, a genus of the digynia order, belonging to the petandria claſs of plants. See Anethum.

DILUTE. To dilute a body, is to render it liquid; or, if it were liquid before, to render it more ſo, by the addition of a thinner thereto. Thoſe things thus added, are called *diluents* or *dilutors*.

DIMENSION, the extenſion of a body, conſidered as meaſurable. Hence as we conceive a body extended, and meaſurable in length, breadth, and depth, we conceive a *trine dimenſion*, viz. length, breadth, and thickneſs. The firſt called a *line*, the ſecond a *ſurface*, the third a *ſolid*.

Dimension is particularly uſed with regard to the powers of the roots, or values of the unknown quantities of equations, which are called the dimenſions of thoſe roots. See Syſtem of Algebra, Sect. V.

DIMINUTION, in architecture, a contraction of the upper part of a column, whereby its diameter is made leſs than that of the lower part. To attain thoſe two important points in architecture, ſtrength and the appearance of ſtrength, all architects have made their columns leſſer above than below, which is called their diminution. See Syſtem of Architecture, on the order of Architecture in general.

Diminution, in rhetoric, the augmenting and exaggerating what you have to ſay, by an expreſſion that ſeems to weaken and diminiſh it. As for inſtance, when a man ſays, with a certain tone, this woman is not ugly; meaning, ſhe is very handſome. Some authors take diminution in a ſtricter ſenſe, viz. for ſaying leſs than a man really means; as You are not, indeed, to be commended; where a greater reproach is ſecretly meant.

DIMINUTIVE, in grammar, a word formed from ſome other, to ſoften or diminiſh the force and effect thereof; or to ſignify a thing that is little in its kind. Thus cellule is a diminutive of cell, globule, of globe; hillock, of hill, &c.

DIMISSORY *Letters*, *Literæ Dimiſſoriæ*, in the canon law, a letter given by a biſhop to a candidate for holy orders, having a title in his dioceſe, directed to ſome other biſhop, and giving leave for the bearer to be ordained by him. When a perſon produces letters of ordination, or tonſure, conferred by any other than his own dioceſan, he muſt at the ſame time produce the letters dimiſſory, given by his own biſhop, on pain of nullity. Letters dimiſſory cannot be given by the chapter, *ſede vacante*; this being deemed an act of voluntary juriſdiction, which ought to be reſerved to the ſucceſſor.

DINNER, the great meal, or that taken about the middle of the day. The word is formed from the French *diſner*, which Du Cange derives from the barbarous Latin *diſnare*. Henry Stephens derives it from the Greek δειπνειν; and will have it wrote *dipner*. Menage deduces it from the Italian *deſinare*, *to dine*; and that from the Latin *deſinere*, *to leave off work*. The grand Tartar, emperor of China, after he has dined, makes publication by his heralds, that he gives leave for all the other kings and potentates of the earth, to go to dinner; as if they waited for his leave. In the general, it is agreed to be the moſt ſalutary to make a ſpare ſupper, and to eat the more plentifully at dinner, eſpecially for tender, valetudinary people. This is the ſentiment of the Schola Salernitana.

Ex magna cœna ſtomocho fit maxima pœna;
Ut ſis nocte levis, ſit tibi cœna brevis.

The Romans, we are aſſured, never minded dinner; but deferred their good cheer to the evening, which they made their grand meal.

DIOCESE, or **Diocess**, the circuit or extent of the juriſdiction of a biſhop. See **Bishop**.

The word is formed from the Greek διοκησις, *government, adminiſtration*, formed of διοικεω, which the ancient gloſſaries render *adminiſtro, moderor, ordino*: hence διοικησις της πολεως, the *adminiſtration* or *government of a city*.

Diocese is alſo uſed, in ancient authors, &c. for the province of a metropolitan.

Diocæſis, Διοικεσις, was originally a civil government, or prefecture, compoſed of divers provinces. The firſt diviſion of the empire into dioceſes is aſcribed to Conſtantine, who diſtributed the whole Roman ſtate into four, viz. the dioceſe of Italy, the dioceſe of Illyria, that of the Eaſt, and that of Africa. And yet, long time before Conſtantine, Strabo, who wrote under Tiberius, take noticee, lib. xiii. p. 432, that the Romans had divided Aſia into dioceſes, and complains of the confuſion ſuch a diviſion occaſioned in geography; Aſia being no longer divided by people, but by dioceſes, each whereof had a tribunal, or court, where juſtice was adminiſtered. Conſtantine, then, was only the inſtitutor of thoſe large dioceſes, which comprehended ſeveral metropoles and governments; the former dioceſes only comprehending one juriſdiction, or diſtrict, or the country that had reſort to one judge, as appears from this paſſage in Strabo, and, before Strabo, from Cicero himſelf, lib. iii. Epiſt. ad Famil. Ep. 9. and lib. xiii. Ep. 67. Thus, at firſt, a province included divers dioceſes, and afterwards a dioceſe came to compriſe divers provinces. In after-times the Roman empire became divided into thirteen dioceſes, or prefectures; though, including Rome, and the ſub-urbicary regions, there were fourteen. Theſe fourteen dioceſes comprehended a hundred and twenty provinces; each province had a pro-conſul, who reſided in the capital, or metropolis; and each dioceſe of the empire had a conſul, who reſided in the principal city of the diſtrict. On this civil conſtitution the eccleſiaſtical one was afterwards regulated; each dioceſe had an eccleſiaſtical vicar, or primate, who judged finally of all the concerns of the church within his territory. At preſent there is ſome farther alteration; for dioceſe does not now ſignify an aſſemblage of divers provinces, but is limited to a ſingle province, under a metropolitan, or even to the ſingle juriſdiction of a biſhop.

England, with regard to its eccleſiaſtical ſtate, is divided into two provinces, viz. Canterbury and York; the former province contains twenty-one dioceſes, and the latter three, beſides the biſhopric of the iſle of Man, which was annexed to the province of York by Henry VIII. Every dioceſe is divided into archdeaconries; and each archdeaconry into rural deanries; and every deanry into pariſhes.

DIODIA, in botany, the name of a genus of the monogynia order of the tetrandia claſs of plants. There is but one ſpecies, See Plate IV. in the Syſtem of **Botany**.

DIODON, or **Sun Fish**, in ichthyology, a genus belonging to the order of amphibia nantes. There are three ſpecies, 1. The oblong ſun fiſh grows to a great bulk: one examined by Sylvianus was above 100 pound in weight; and Dr. Borlaſe mentions another taken at Plymouth in 1734, that weighed 500. In form it reſembles a bream or ſome deep fiſh.

When boiled, it has been obſerved to turn into a glutinous jelly, reſembling boiled ſtarch when cold, and ſerved the purpoſes of glue on being tried on paper and leather. The meat of this fiſh is uncommonly rank: it feeds on ſhell fiſh.

2. The mola or ſhort ſun fiſh, differs from the former, in being much ſhorter and deeper. The back and the anal fins are higher, and the aperture to the gills not ſemilunar, but oval. The ſituation of the fins are the ſame in both. Both kinds are taken on the weſtern coaſts of this kingdom, but in much greater numbers in the warmer parts of Europe.

3. The levigatus, or globe, is common to Europe and South Carolina. As yet only a ſingle ſpecimen has been diſcovered in our ſeas; taken at Penzance, in Cornwall.

DIOECIA, (from δις, *twice*, and οικια, a *houſe* or *habitation*) two houſes. The name of the 22d claſs in Linnæus's ſexual method, conſiſting of plants, which having no hermaphrodite flowers, produce male and female flowers on ſeparate roots. See Syſtem of **Botany**, Sect. V. Plate VI.

DIOMEDIA, in ornithology, a genus belonging to the order of anſeres. The bill is ſtrait; the ſuperior mandible is crooked at the point, and the lower one is truncated; the noſtrils are oval, open, a little prominent, and placed on the ſides. There are two ſpecies, viz. 1. The exulans, has pennated wings, and three toes an each foot. It is the albatros of Edwards; and is found in the ocean betwixt the tropics, and at the Cape of Good Hope. It flies pretty high, feeds upon flying fiſh, and is about the ſize of a pelican. 2. The demerſa, has no quill feathers on the wings; and the feet have four toes, connected together by a membrane. It is the black penguin of Edwards, about the ſize of a gooſe, and is found at the Cape of Good Hope. See Synoptical table in Syſtem of **Ornithology**.

DIONÆA Muscipula, or *Venus's Fly Trap*, in botany, a newly diſcovered ſenſitive plant.

Every one ſkilled in natural hiſtory knows, that the minoſæ, or ſenſitive plants, cloſe their leaves, and bend their joints, upon the leaſt touch: and this has aſtoniſhed us; but no end or deſign of nature has yet appeared to us from theſe ſurpriſing motions: they ſoon recover themſelves again, and their leaves are expanded as before. But the plant we are now going to deſcribe, ſhews that nature may have ſome view towards its nouriſhment, in forming the upper joint of its leaf like a machine to catch food: upon the middle of this, lies the bait for the unhappy inſect that becomes its prey. Many minute red glands that cover its inner ſurface, and which perhaps diſcharge ſome ſweet liquor, tempt the poor animal to taſte them; and the inſtant theſe tender parts are irritated by its feet, the two lobes riſe up, graſp it faſt, lock the two rows of ſpines together, and ſqueeze it to death. And further, leſt the ſtrong efforts for life, in the creatures thus taken, ſhould ſerve to diſengage it, three ſmall erect ſpines are fixed near the middle of each lobe among the glands, that effectually put an end to all its ſtruggles. Nor do the lobes ever open again, while the dead animal continues there. But it is nevertheleſs certain, that the plant cannot diſtinguiſh an animal from a mineral ſubſtance; for, if we introduce a ſtraw or a pin between the lobes, it will graſp it full as faſt as if it was an inſect. The plant is one of the monogynia order, belonging to the decandria claſs. It grows in America, about 35 deg. N. Lat. in wet ſhady places, and flowers in July and Auguſt. See Syſtem of **Botany**, Plate IV.

The ſoil in which it grows, as appears from what comes about the roots of the plants when they are brought over, is a black, light, mould, intermixed with white ſand, ſuch as is uſually found in our mooriſh heaths. Its ſenſitive quality will be found in proportion to the heat of the weather as well as the vigour of the plant. In order to try further experiments on its ſenſitive power, ſome of the plants might be placed in pots of light mooriſh earth and placed in pans of water, in an airy ſtove in ſummer; where the heat of ſuch a ſituation being like that of its native country will make it ſurpriſingly active.

DIOPTRICS, the doctrine of refracted viſion, called alſo anaclaſtics. The word is originally Greek, formed of δια, *per, through*, and οπτομαι, *I ſee*. Dioptrics is properly the third branch of optics, its office being to conſider and to explain the effects of light refracted by paſſing through different mediums, as air, water, glaſs, &c. and eſpecially lenſes. For a full deſcription of this branch of Optics, ſee the Syſtem.

DIORTHOSIS, διορθωσις, in ſurgery, an operation, by which crooked or diſtorted members are made even, and reſtored to their primitive and regular ſhape.

DIOSCOREA, in botany, a genus of the hexandria order, belonging to the diœcia claſs of plants, for which there is no Engliſh name. There are eight ſpecies, of which the only remarkable one is the bulbifera or yam; for the claſs and order, ſee Syſtem of **Botany**, Sect. V. Plate VI.

DIOSPYROS, the Indian date plum, a genus of the diœcia order belonging to the polygamia claſs of plants. There are two ſpecies. For the claſs and order, ſee Syſtem of **Botany**, Plate VI.

DIPHTHONG, διφθογγος, in grammar, a double vowel, or the union, or mixture, of two vowels pronounced together, ſo as only to make one ſyllable; as (1) the Latin *ae*, or *æ*; *oe*, or *œ*; (2) the Greek *αι*, *ει*; (3) the Engliſh *ai*, *au*; &c. The word is Greek, and is compounded of δις, *twice*, and φθογγος, *ſound*. See **Grammar**.

DIPLOE, from διπλοος, *double*, in anatomy, a ſpongy, medullary ſubſtance, ſeparating the two tables of the cranium, and together with them conſtituting the ſkull.

DIPLOMA, from διπλοος, *double*, an inſtrument given by colleges and ſocieties, on taking a degree, on paſſing examination, as a proof or qualification for any advancement to title, or pre-eminence, or introduction to the exerciſe of a profeſſion.

DIPPING, in mineralogy, a term uſed to expreſs the deviation of the veins of ore, from that regular and ſtraight line in which they uſually run.

Dipping *Needle*, *or Inclinatory Needle*, a magnetical needle, ſo hung, as that, inſtead of playing horizontally, and pointing out north and ſouth, one end dips, or inclines to the horizon, and the other points to a certain degree of elevation above it; ſee **Needle**.

DIPSACUS, teazel; a genus of the monogynia order, belonging to the tetrandia claſs of plants. There are four ſpecies, the moſt remarkable of which is the carduus fullonum, which grows wild in many parts of England. It is of ſingular uſe in raiſing the knap upon woollen cloth. For this purpoſe, the heads are fixed round the circumference of a large broad wheel, which is made to turn round, and the cloth is held againſt them. In the weſt of England, great quantities of the plant are cultivated for the uſe juſt now mentioned. It is propagated by ſowing the ſeeds in March, upon a ſoil that is well prepared. See Syſtem of **Botany**, Sect. V. Plate IV.

DIPSAS, a ſort of ſerpent, the biting whereof produces ſuch a thirſt as proves mortal; whence it is called *dipſas*; which in Greek ſignifies *thirſty*. In Latin it is called *ſitula*, a *pail*. Moſes ſpeaks of it in Deut. viii. 15.

The Hebrew word *tzimaon* anſwers very well to the Greek *dipſas*, and expreſſes the thirſt occaſioned by the biting of this ſerpent. Some by the Hebrew *tzimaon* underſtand a deſart, or dry place.

DIPTERA, from δις, and πτερον, *wing*, in entomology, an order of inſects, which have only two wings, and under each wing a ſtyle or oblong body, terminated by a protuberance or head, and called a balancer.

DIPTOTES, from δις, and πτωτος, of πιπτω, *cado*, in grammar, a kind of irregular nouns, having only two caſes; as *fors*, *forte*.

DIRECT, in arithmetic. The *Rule of Three* Direct is that oppoſite to the inverſe.

Direct, in aſtronomy. We conſider the planets in three ſtates; viz. direct, ſtationary, and retrograde. They are ſaid to be direct, when they appear to move forward, according to the ſucceſſion of the ſigns; and retrograde, when they go the contrary way.

Direct, in matters of genealogy, is underſtood of the principal line, or the line of aſcendants and deſcendants: in contradiſtinction to the collateral lines. Thus the houſe of Bourbon is ſaid to deſcend in a direct line from St. Louis. The heirs in a direct line always precede thoſe in the collateral line.

A very good hiſtorian uſes the phraſe Direct *Speech*, or *Harangue*, when he introduces any one ſpeaking, or haranguing of himſelf: when the hiſtorian ſpeaks, and only rehearſes the chief points of what was delivered by the ſpeaker, it is called an *indirect ſpeech*.

Direct $\left\{\begin{matrix}\textit{Erect}\\ \textit{Eaſt}\\ \textit{Weſt}\end{matrix}\right\}$ *Dials*, are thoſe whoſe planes lie directly open to the eaſt or weſt points of the heavens, or parallel to the meridian of the place.

Direct *South* or *North* $\left\{\begin{matrix}\textit{Inclining}\\ \textit{Reclining}\end{matrix}\right\}$ *Dials*. See Treatiſe on Dialling, Sections VI. and VII.

Direct, in muſic, is a mark ſet at the end of a ſtaff, eſpecially at the foot of a page upon that line or ſpace where the firſt notes of the next ſtaff is ſet.

Direct, in optics. Direct viſion is that performed by direct rays; in contradiſtinction to viſion by refracted or reflected rays. Direct viſion is the ſubject of optics, which preſcribes the laws and rules thereof.

Direct *Rays* are thoſe which paſs in right lines from the luminary to the eye, without being turned out of their rectilinear direction by any intermediate body, either opaque or pellucid. See Syſtem of Optics.

Direct *Sphere*. See Right *Sphere*.

DIRECTION, in aſtronomy, the motion, and other phenomina, of a planet, when direct.

Direction, or *Line of* Direction, in mechanics, is particularly uſed for a line paſſing from the centre of the earth through the centre of gravity of a body, and the ſupport or fulcrum that bears it. A man muſt neceſſarily fall down as ſoon as the centre of his gravity is out of the *line of direction*.

Line of Direction, in mechanics, alſo denotes that wherein a body moves, or endeavours to proceed.

Angle of Direction, in mechanics, is that comprehended between the lines of direction of two conſpiring powers.

Quantity of Direction, in mechanics, is uſed for the product of the velocity of the common centre of gravity in a ſyſtem of bodies, by the ſum of their maſſes. In the colliſion of bodies, the quantity of direction is the ſame before, and after the impulſe. Bernouilli, Diſcours ſur le Movement. Oper. tom. iii. p. 32, and 56.

Direction *of the Load Stone*, that property whereby the magnet, or a needle touched by it, always preſents one of its ends towards one of the poles of the world, and the oppoſite end to the other pole. The attractive property of the magnet was known long before its directive; and the directive long before the inclinatory.

Magnetical Direction, is alſo uſed in the general for the tendency, or turning of our earth, and all magnetical bodies, to certain points. The direction of a load ſtone denotes its polarity.

DIRECTLY. In geometry, we ſay, two lines lie directly againſt each other, when they are parts of the ſame right line. In mechanics, a body is ſaid to ſtrike, or impinge directly againſt another, if it ſtrike in a right line perpendicular to the point of contact. A ſphere, particularly, ſtrikes directly againſt another when the line of direction paſſes through both their centres.

DIRECTOR, in commercial polity, a perſon who has the management of the affairs of a trading company: thus we ſay, the directors of the India Company, South-ſea Company, &c.

Director, in ſurgery, a grooved probe, to direct the edge of the knife or ſciſſars in opening ſinuſes or fiſtulas, that, by this means, the ſubjacent veſſels, nerves, and tendons, may remain unhurt.

DIS, an inſeparable particle prefixed to divers words; the effect whereof is, either to give them a ſignification contrary to what the ſimple words had: as in *diſgrace*, *diſparity*, *diſproportion*, &c. or to intimate a ſeparation, detachment, diſtribution, &c. as in *diſcerning*, *diſcourſing*, *diſtracting*, *diſpoſing*, &c.

DISABILITY, in law, is when a man is made incapable to inherit lands, or take any benefit, which otherwiſe he might do; which may happen four ways; viz. by the act of the anceſtor; by the act of the party; by the act of law; and by the act of God.

Disability *by the Act of the Anceſtor*, is where the man is attainted of treaſon, or felony; by which attainder his blood is corrupted, and thereby himſelf and his children are diſabled to inherit.

Disability *by the Act of the Party himſelf*, is where a man binds himſelf by obligation, that upon a ſurrender of a leaſe, he will grant a new eſtate to the leſſee; and afterwards he grants the reverſion to another, which puts it out of his power to perform it.

Disability *by the Act of the Law*, is when a man, by the ſole act of law, without any thing by him done, is rendered incapable of the benefit of the law: as, an alien born; ſo that if a man born out of the king's liegeance, will ſue an action, the tenant, or defendant, may ſay, he was born in ſuch a country out of the king's liegeance, and demand judgment, if he ſhall be anſwered; for the law is our birth-right, to which an alien is a ſtranger, and therefore diſabled from taking any benefit thereby.

Disability *by the Act of God*, is when the party is *non compos mentis*, or *non ſanæ memoriæ*, which ſo diſables him, that in all caſes, where he gives, or paſſes any thing, or eſtate from him, after his death it may be annulled, and avoided. There are alſo other diſabilities by the common law, as of idiocy, infancy, and coverture, for making of grants, &c. and by ſtatute, as papiſts are diſabled for making any preſentation to a church, &c. and officers not taking the oaths for holding offices.

DISABLED, in ſea language, is applied to a ſhip, when by the loſs of her maſts, yards, or rigging, or other damage, ſhe is rendered incapable of proſecuting her voyage, without great difficulty and danger.

DISARMING, the act of depriving a perſon of the uſe or poſſeſſion of arms. On the concluſion of a peace, it is uſual for both ſides to diſarm. We have divers laws for diſarming papiſts, and all recuſants. Under king George I. a law was made for diſarming the highlanders; none of whom, except peers, or gentlemen of 400l. per annum, are to wear any arms in the field, on the road, or at market. 1 Geo. I. ſtat. 2. cap. 54. The game law has, in effect, diſarmed all the common people of England, having under 100l. a year in landed eſtate, except the ſervants of lords of manors. Yet, by the ancient policy of England, the whole nation was obliged to bear arms.

DISC, or Disk, in aſtronomy, the body and face of the ſun and moon, ſuch as it appears to us on the earth; or the body and face of the earth, ſuch as it appears to a ſpectator in the moon. See Syſtem of Astronomy, Sect. VIII.

Disc, in optics, is the width of the aperture of teleſcopic glaſſes, whatever their form be, whether plain, convex, concave, &c. See account of Teleſcopes, in Syſtem of Optics.

DISCERNING, an act of the mind, whereby it diſtinguiſhes between ideas. See Metaphysics.

DISCHARGE, in military language, is the diſmiſſion of a ſoldier from the troop or company to which he belonged, either by his own requeſt, or when after long and faithful ſervice, he is entitled to his majeſty's bounty.

To Discharge, in ſea language, ſignifies to unload a ſhip, or take out her ſtores, ammunition, artillery, &c. When applied to the crew, it implies to diſband them from immediate ſervice.

DISCHARGER, or Discharging *Rod*, in electricity. See Syſtem of Electricity, Plate II. *Fig*. 25.

DISCIPLE, from *diſco*, *I learn*, one who learns any thing from another. Thus the followers of any teacher, philoſopher, &c. are called diſciples. In the Chriſtian ſenſe, they were the followers of Jeſus Chriſt, in general; but in a more reſtrained ſenſe, the diſciples denote thoſe alone who were the immediate followers and attendants on his perſon; of which there were 70 or 72. The names diſciple and apoſtle are often ſynonymouſly uſed in the goſpel hiſtory; but ſometimes the apoſtles are diſtinguiſhed from diſciples, as perſons ſelected from them to be the principal miniſters of his religion; of theſe there were only twelve. The Latins keep the feſtival of the ſeventy, or ſeventy-two diſciples, on July 15; and the Greeks on January 4.

DISCIPLINE, in a general ſenſe, denotes inſtruction and government, as military diſcipline, eccleſiaſtical diſcipline, &c.

Eccleſiaſtical diſcipline conſiſts in putting thoſe laws in execution by which the church is governed, and inflicting the penalties enjoined by them againſt the ſeveral ſorts of offenders that profeſs the religion of Jeſus. Diſcipline, in a more peculiar ſenſe, is uſed for the chaſtiſements or bodily puniſhments inflicted on a religious of the Romiſh church who has been found a delinquent; or even for that which the religious voluntarily undergo or inflict on themſelves, by way of mortification.

DISCLAIMER, in law, a plea, containing an expreſs denial, renouncing, or diſclaiming, of a thing alleged.

In chancery, if a defendant by his anſwer renounces having any intereſt in the thing in queſtion, this is a diſclaimer: to which may be added, a diſclaimer by renouncing an executorſhip of a will, or the right to an adminiſtration.

DISCONTINUANCE, an interruption, intermiſſion, or ceſſation, of the courſe of a thing: as diſcontinuance of poſſeſſion, of a plea, proceſs, &c.

DISCORD, in general, ſignifies diſagreement, or oppoſition between different perſons or things.

Discord, in muſic, every ſound which, joined with another, forms an aſſemblage diſagreeable to the ear; or rather, every interval whoſe extremes do not coaleſce. Now, as there are no other concords or conſonances, except thoſe which form amongſt themſelves, and with their fundamental ſound, perfect chords, it follows, that every other interval muſt be a real diſſonance or diſcord: even the third and ſixth were reckoned ſuch among the ancients, who excluded them from the number of conſonant chords. See Syſtem of Music.

DISCOVERY, in a general ſenſe, the act of finding out any thing hidden; ſhewing any thing concealed or covered; or revealing any thing ſecret.

Discovery, in law, the act of revealing or diſcloſing any matter by the defendant, in his anſwer to a bill filed againſt him in a court of equity.

Discovery *of Accomplices* is provided for in the caſes of robbery, burglary, houſe breaking, and larceny, to the value of five ſhillings, from ſhops, ware houſes, ſtables, and coach houſes, by 4 and 5 W. and M. cap. 8. 10 and 11 W. III. cap. 23. and 5 Anne, cap. 31. which enact, that if any ſuch felon, being out of priſon, ſhall diſcover two or more perſons who have committed the like felonies, ſo that they may be convicted, he ſhall in moſt caſes receive a reward of 40*l.* and in general be entitled to a pardon of all capital offences, excepting only murder and treaſon. And if any ſuch perſon having feloniouſly ſtolen any lead, iron, or other metals, ſhall diſcover and convict two offenders of having illegally bought or received the ſame, he ſhall by ſtat. 29 Geo. II. cap. 30. be pardoned for all ſuch felonies committed before ſuch diſcovery.

Discovery, in dramatic poetry, a manner of unravelling a plot or fable, very frequent in tragedies and comedies, wherein, by ſome unforeſeen accident, a diſcovery is made of the name, fortune, quality, and other circumſtances, of a principal perſon, which were before unknown.

DISCOUNT, in commerce, a term among traders, merchants, and bankers. It is uſed by the two former on occaſion of their buying commodities on the uſual time of credit, with a condition that the ſeller ſhall allow the buyer a certain diſcount at the rate of ſo much per cent. per annum, for the time for which the credit is generally given, upon condition that the buyer pays ready money for ſuch commodities, inſtead of taking the time of credit. Traders and merchants alſo frequently taking promiſſory notes for monies due payable to them or order at a certain time, and ſometimes having occaſion for money before the time is elapſed, procures theſe notes to be diſcounted by bankers before the time of payment. Bills of exchange are alſo diſcounted by bankers; and in this conſiſts one article of the profits of banking.

DISCOURSE, in logic, from *diſcurro, I run over*, an operation of the human mind, whereby it paſſes or proceeds from one thing to another, that is, from a known thing to an unknown.

Discourse, in a general ſenſe, denotes converſation, wherein perſons mutually convey their ideas or ſentiments to each other; a treatiſe or diſſertation written or uttered.

DISCRETION, in law, the faculty of diſcerning between right and wrong; and therefore whoever hath power to act at diſcretion, is bound by the rule of reaſon and law. 2 Inſt. 56. 298. Infants, &c. under the age of diſcretion, are not puniſhable for crimes: and want of diſcretion is a good exception againſt a witneſs. 2 Hauk. 434.

DISCRETIVE *Propoſitions*, are thoſe where various judgments are made, and denoted, by the particles *but*, *notwithſtanding*, or by words of the like nature, either expreſſed or underſtood. Thus, fortune may deprive me of my wealth, *but* not of my virtue; they, who croſs the ſeas, change their climate, *but* not their diſpoſition; are called *diſcretive propoſitions*.

DISCUSSION, in matters of literature, ſignifies a clear treating or handling of any point, or problem. The word imports a ſhaking off, or diſpelling the difficulties and obſcurities with which a thing was embarraſſed. We ſay, ſuch a point was well diſcuſſed, when it was well treated of, and cleared up.

Discussion is alſo uſed in a medicinal ſenſe, for a diſperſing the matter of any tumor, or ſwelling, through the pores of the body; or an evacuation of ſome thin matter gathered in any part, by inſenſible perſpiration.

DISCUTIENTS, in medicine, either repellers or remedies proper to open the pores, and evacuate the redundant or peccant humours of the body by inſenſible perſpiration or otherwiſe. Diſcutients are in this laſt ſenſe the ſame with what we otherwiſe call diaphoretics.

DISEASE, in medicine, that ſtate of a living body, wherein it is prevented the exerciſe of any of its functions, whether vital, natural, or animal. Or, is a depravity and diſorderly ſtate of the ſolid and fluid parts; whereby all, or ſome of the functions either of the body, or mind, or both, are either aboliſhed, or impaired.

Of all animals, man is ſubject to the moſt diſeaſes; and of men, the ſtudious and ſpeculative are moſt expoſed thereto. Other animals have their diſeaſes; but they are in ſmall number: nor are plants without them. Some diſeaſes only impair the uſe of the part immediately affected; as the ophthalmia, gout, &c. Others deſtroy it entirely; as the gutta ſerena, palſy, &c. Some affect the whole body; as the fever, apoplexy, epilepſy, &c. Others only impair a part; as the aſthma, colic, dropſy, &c. Some only affect the body; as the gout: others diſturb the mind, as melancholy, delirium, &c. Laſtly, others affect both the body and mind; as the mania, phrenſy, &c.

The colder the country, in general, the fewer and the leſs violent are the diſeaſes. Scheffer tells us, that the Laplanders know no ſuch thing as the plague or fevers of the burning kind; nor are ſubject to half the diſtempers we are. They are robuſt and ſtrong, and live to eighty, ninety, and many of them to more than a hundred years: and at this great age, they are not feeble and decrepid, as with us, but a man of ninety is able to work, or travel, as well as a man of ſixty with us. They are ſubject, however, to ſome diſeaſes more than other nations: thus they have often diſtempers of the eyes, which is owing to their living in ſmoak, or being blinded by the ſnow. Pleuriſies and inflammations of the lungs are alſo very frequent among them; and the ſmall pox often rages with great violence.

The credulity of the public was never more evident, than in the impoſition practiſed by the late exhibitor of thoſe beings called *Monſtrous Craws*, as ſubjects rare and ſingular; whereas the cauſes which excited their curioſity, are common to all the natives of the Alps, as well as ſeveral other parts of Italy.

It has been always obſerved, that people of particular places were peculiarly ſubject to particular diſeaſes which are owing to their manner of living, or to the air, and effluvia of the earth and waters. Hoffman has made ſome curious obſervations on diſeaſes of this kind. He obſerves, that ſwellings of the throat have always been common to the inhabitants of mountainous countries; and the old Roman authors ſay, who wonders at a ſwelled throat in the Alps? The people of Swiſſerland, Carynthia, Styria, the Hartz foreſt, Tranſylvania, and the inhabitants of Cronſtadt, he obſerves, are all ſubject to this diſeaſe from the ſame cauſe. See Bronchocele.

The French are peculiarly troubled with fevers, with worms, and with hydroceles and ſarcoceles; and all theſe diſorders ſeem to be owing originally to their eating very large quantities of cheſnuts. The people of our own nation are peculiarly afflicted with hoarſeneſſes, catarrhs, coughs, dyſenteries, conſumptions, and the ſcurvy: and the women with the *fluor albus*, or whites, and children, with a diſeaſe ſcarce known elſewhere, which we call the rickets. In different parts of Italy, different diſeaſes reign. At Naples, the venereal diſeaſe is more common than in any other part of the world. At Venice, people are peculiarly ſubject to the bleeding piles. At Rome, tertain agues, and lethargic diſtempers are moſt common. In Tuſcany, the epilepſy, or falling ſickneſs. And in Apulia they are moſt ſubject to burning fevers, and pleuriſies.

In Spain, apoplexies are common, as alſo melancholy, hypochondriacal complaints, and bleeding piles. The Dutch are peculiarly ſubject to the ſcurvy, and to the ſtone in the kidneys. Denmark, Norway, Sweden, Pomerania, and Livonia, are all terribly afflicted with the ſcurvy: and it is remarkable, that in Denmark, Sweden, and Norway, fevers are very common; but in Iceland, Lapland, and Finland, there is ſcarce ever ſuch a diſeaſe met with; though peripneumonies are very common in theſe places, as alſo diſeaſes of the eyes and violent pains of the head. The Ruſſians and Tartars are afflicted with ulcers, made by the cold, of the nature of what we call chilblains, but greatly worſe; and in Poland and Lithuania there reigns a peculiar diſeaſe, called the *plica polonica*, ſo terribly painful and offenſive, that ſcarce any thing can be thought of worſe. The people of Hungary are very ſubject to the gout and rheumatiſm: they are alſo more infeſted with lice and fleas than any other people in the world, and they have a peculiar diſeaſe which they call cremor.

The Germans, in different parts of the empire, are ſubject to different reigning diſeaſes. In Weſtphalia, they are peculiarly troubled with peripneumonies and the itch. In Sileſia, Franconia, Auſtria, and other places thereabout, they are very liable to fevers of the burning kind, to bleedings at the noſe, and other hæmorrhages; and to the gout, inflammations, and conſumptions. In Miſnia, they have purple fevers; and the children are peculiarly infeſted with worms. In Greece, Macedonia, and Thrace, there are very few diſeaſes; but what they have, are principally burning fevers and phrenſies. At Conſtantinople the plague always rages; and in the Weſt Indian iſlands, malignant fevers, and the moſt terrible colics. Theſe diſeaſes are called *endemic*.

As the actions, or conditions of the body, ſo alſo the diſeaſes, or defects thereof, may be reduced to three general heads; viz.

1. Diſeaſes of the ſolid parts. 2. Thoſe of the fluid parts. And, 3. Diſeaſes compounded of both.

Diseases *Feigned*. The cheat of feigning diſeaſes, for idleneſs, or profit ſake, or for other occaſional purpoſes, has been too common in all ages, and is too difficult to be diſcovered in all caſes; though, in many, there are ways of coming at the truth. We have had a very late inſtance of a young lady, who puzzled ſeveral of our beſt phyſicians, to account for the nature of a diſeaſe, which ſhowed itſelf in a ſingular kind of excoriations; and the ſecret perhaps had never been diſcovered, had not a bottle of aqua fortis been accidentally found in her chamber; the touching the arms, &c. with which, had occaſioned all the appearances, which ſome ſtrange fault in the juices had been before accuſed of.

Diſſimulation in regard to diſeaſes, may be reduced to three kinds. In the firſt, the ſickneſs is pretended by words only, and really is not: of this nature are the pretended head-ach, colic, and the like; which, as the patient can only know, the phyſician may be always deceived. In the ſecond, there are not only words for teſtimonies of the ſickneſs, but there appear ſigns and marks of it on the body, which yet are only counterfeited to ſerve certain purpoſes. Scabbineſs, leproſy, even the exulceration of the lungs, may be thus counterfeited; the laſt by a pretended ſpitting of blood. Gravidation is often pretended alſo. Our beggars often contrive the means of theſe to excite compaſſion. In the third kind of diſſimulation of diſeaſes, we are to include the concealing a diſeaſe; which really exiſts, inſtead of the owning of one which does not.

In the diſcovery of theſe deceits, on which the credit of the phyſician often depends, it is not mere medical knowledge that will ſucceed, but there muſt be added to it a ſagacity in exploring all circumſtances and outward accidents, and eſpecially thoſe things which relate to the genius, temper, and ſtate of the perſon ſuſpected.

The impoſitions practiſed by feigning diſeaſes have lately been more prevalent than ever, eſpecially amongſt thoſe abetted from venal conſiderations, by pretenders to animal magnetiſm. This ſpecies of fraud originated in France, where through the ſubtelty of the practitioner Doctor Meſmer, and the gallantries it was deſigned to conceal, it gained general credit, and proved a moſt lucrative employ, till the faculty inveſtigated it by order of the king, and exploded the doctrine as palpably deluſive.

An adventurer from France however, relying on the credulity of our nation, undertook to introduce it here, and by means of the affected emotions of paupers ſuborned for the purpoſe of colluſion, brought it into a degree of eſtimation, and continues to practiſe with ſome emolument. Others, inſtigated by the reputation it acquired, have adopted the ſame plan of deluſion, amongſt theſe are a Pſeudo or horſe doctor, and vender of quack medicines, whoſe notoriety need no further explanation; and a well known character, lately reſident at Hammerſmith, whoſe deſign we are candidly induced to think was rather to raiſe his name, than improve his fortune. We paſs theſe current remarks to teſtify our averſion to pretenders and impoſtors.

Diseases *of Plants*. 1. The too great abundance of the nutritious juice. 2. The defect, or want of this juice. 3. Some ill qualities it acquires. 4. Its unequal diſtribution in different parts of the plant. And, 5. External accidents. 1. The diſeaſes principally obſerved by our gardeners, are, 1. Barrenneſs, when the tree, though ſeeming freſh and healthy, bears no bloſſoms: or, if it does, they ſoon fall; or, if they ſet, the fruit drops before it comes to maturity. 2. Blaſting of the buds, occaſioned by a froſt happening when the leaves and bloſſoms are wet; by this means the pores are ſhut, and the vital juices ſuffocated: when if the ſun break out on a ſudden, they turn yellow, with round fiery ſpecks growing on them; whence frequently proceed tumors, like warts, which, rotting, grow full of maggots. Mr. Mortimer adds, that the want of rain in bloſſoming time, often occaſions the dropping off of the bloſſoms, for want of ſap; he, therefore, recommends the watering of them. 3. Conſumption, proceeding from a want of ſuſtenance, through the failure of the nouriſhing juices, or from obſtructions of the veins and roots; or ill digeſtion, and ſecretion of humours, &c. See Blight and Mildew.

DISFRANCHISING, among civilians, ſignifies the depriving a perſon of the rights and privileges of a free citizen or ſubject.

DISGUISE, a counterfeit habit. Perſons doing unlawful acts in diſguiſe are by our ſtatutes ſometimes ſubjected to great penalties, and even declared felons. Thus by an act, commonly called the black act, perſons appearing diſguiſed and armed in a foreſt or grounds incloſed, or hunting deer, or robbing a warren or a fiſhpond, are declared felons.

DISJUNCTIVE, ſomething that ſeparates, or disjoins. Thus, *or*, *neither*, &c. are called disjunctive conjunctions; which, in connecting a diſcourſe, do yet ſeparate the parts thereof. E. gr. *Aut Cæſar, aut nullus*; *either Cæſar, or nothing*. He *neither* advanced, *nor* gave back. Disjunctive conjunctions may alſo be called *partitive*, *diſtributive*, and *alternative*.

Disjunctive *Propoſitions*, in logic, are compound propoſitions, conſiſting of two members, or parts, connected by a disjunctive conjunction.

DISLOCATION, the putting a bone out of joint, by ſome violence, uſually called by the faculty, luxation. We have an inſtrument of Mr. Freke's invention for the reduction of diſlocated ſhoulders, deſcribed in the Philoſophical Tranſactions, Nº 470.

DISMASTED, in ſea language, denotes the ſtate of a ſhip, when ſhe has loſt her maſts by engagement, or bad weather.

DISMEMBERED, in heraldry, is applied to birds that have neither feet nor legs; as alſo to lions and other animals, whoſe members are ſeparated.

DISMISSION *of a Bill*, in chancery. If the plaintiff does not attend on the day fixed for the hearing, his bill is diſmiſſed with coſts. It may be alſo diſmiſſed for want of proſecution, which is in the nature of a non-ſuit at law, if he ſuffers three terms to elapſe without moving forward in the cauſe.

DISMOUNTING, in the military art, the act of unhorſing. Thus, to diſmount the cavalry, the dragoons, or the like, is to make them alight. *Diſmount the Canon*, is to break their carriages, wheels, and axle trees, ſo as to render them unfit for ſervice. Horſes are alſo diſmounted when they are rendered unfit for ſervice.

DISPARAGEMENT, in law, is uſed for the matching an heir, &c. in marriage, below his or her degree or condition; or againſt the rules of decency. The word is a compound of the privative particle *dis*, and *par*, *equal*.

DISPART, in gunnery, is uſed for ſetting a mark on the muzzle ring of a piece of ordnance; ſo that a ſight line taken upon the top of the baſe ring againſt the touch-hole, by the mark ſet on or near the muzzle, may be parallel to the axis of the concave cylinder.

DISPATCH, a letter on ſome affair of ſtate, or other buſineſs of importance, ſent with care and expedition, by a courier expreſs. The buſineſs of diſpatches lies on the ſecretaries of ſtate, and their clerks. The king gives directions to his miniſters abroad by diſpatches. The word is alſo uſed for the packet, or mail, containing ſuch letters.

DISPENSARY, or Dispensatory, a name given to divers collections of recipes for compound medicines, wherein are ſpecified the ingredients, propoſitions, and circumſtances, of the preparation and mixture; the ſame with what we otherwiſe call a *pharmacopœia*, or *antidotary*. Such are the diſpenſaries of the college of phyſicians at London and Edinburgh, Quincy, &c. The apothecaries, in and about London, are obliged to make up their compound medicines according to the formulas preſcribed in the College Diſpenſary, and are enjoined to keep always ready in their ſhops, all the medicines therein enumerated.

Dispensary is likewiſe uſed for a magazine or office of medicines, kept ready to be diſpenſed at the prime coſt of the ingredients, for the benefit of the ſick poor. There are at this time ſeveral ſupported by voluntary contribution, where the poor have both advice and medicines gratis.

DISPENSATION, in law, &c. a permiſſion to do ſomething contrary to the ſtanding laws; or a relaxation, or ſuſpenſion of a law, on ſome juſt occaſion. Some confound diſpenſation with equity; but they are very different things; for equity is only the correction, or modification, of a law which is too general; but a diſpenſation ſuſpends the obligation of the law itſelf, and can, therefore, be only given by the legiſlative power.

The king of France grants diſpenſations of age to ſome officers, to be admitted before the legal age: but the greateſt dealer in diſpenſations is the pope, who claims the office, *jure divino*, and extends it to every thing: indeed, the more ſober of the Romaniſts themſelves deny that he can give a diſpenſation for a thing contrary either to the divine law, or the law of nature.

Dispensation *of the King*, makes a thing prohibited lawful to be done by the perſon that has it, though a thing evil in itſelf will not admit of a diſpenſation. When an offence wrongs none but the king, or if the ſuit is only the kings for the breach of a penal law, that is not to the damage of a third perſon, the king may diſpenſe: but in caſe the ſuit is the king's, for the benefit of another, he cannot. It was formerly held, that the king might in many caſes diſpenſe with penal ſtatutes, and the exerciſe of this diſpenſing power was one of the moſt ignominious badges of ſlavery and engines of tyranny, which ever diſgraced and harraſſed this country; but by 1 W. and M. ſtat. 2. c. 2. it is declared, that the ſuſpending or diſpenſing with laws by regal authority, without the conſent of parliament, is illegal: it is alſo a maxim in law, that it requires the ſame ſtrength to diſſolve as to create an obligation. See Blackſt. Com. vol. i. p. 142. 185. 342. and vol. ii. p. 429, 432.

Dispensation, in pharmacy, the diſpoſition and arrangement of ſeveral medicines, either ſimple or compound, all weighed in their proper doſes, or quantities; in order to be employed in the making of a compoſition.

DISPERSION, in dioptrics. *Point of diſperſion*, is a point from which refracted rays begin to diverge, when their refraction renders them divergent. It is called *point of diſperſion*, in oppoſition to the point of concourſe, which is the point wherein converging rays concur after refraction. But the latter is more uſually called *focus*, and the former, *virtual focus*.

Diſperſion *of Mankind*, in the hiſtory of the world, was occaſioned by the confuſion of tongues, and took place in conſequence of the overthrow of Babel at the birth of Peleg; whence he derived his name: and it appears by the account given of his anceſtors, Gen. chap. xi. 10—16. to have happened in the 101ſt year after the flood, according to the Hebrew chronology, and by the Samaritan computation in the 401ſt. However, various difficulties have been ſuggeſted by chronologers concerning the true æra of this event.

Sir John Marſham and others, in order to reconcile the Hebrew and Egyptian chronologies, maintain a diſperſion of mankind before the birth of Peleg: others, unable to find numbers ſufficient for the plantation of colonies in the ſpace of 101 years, according to the Hebrew computation, fix the diſperſion towards the end of Peleg's life, thus following the computation of the Jews: Petavius aſſigns the 153d year after the flood; Cumberland, the 180th: and Uſher, though he generally refers it to the time of Peleg's birth, in one place aſſigns the 131ſt after the flood for this event. Mr. Shuckford ſuppoſes the diſperſion to have been gradual, and to have commenced with the ſeparation of ſome companies at the birth of Peleg, and to have been completed thirty one years after. According to the calculation of Petavius, the number of inhabitants on the earth at the birth of Peleg amounted to 32,768; Cumberland makes them 30,000; Mr. Mede ſtates them at 7000 men, beſides women and children; and Mr. Whiſton, who ſuppoſes that mankind now double themſelves in four hundred years, and that they doubled themſelves between the deluge and the time of David in ſixty years at a medium, when their lives were ſix or ſeven times as long as they have been ſince, by his computation, produces about 2389, a number much too inconſiderable for the purpoſes of ſeparating and forming diſtinct nations. This difficulty induced Mr. Whiſton to reject the Hebrew, and to adopt the Samaritan chronology; as many others have done; which, by allowing an interval of 401 years between the flood and the birth of Peleg, furniſhes, by the laſt mentioned mode of computation, more than 240,000 perſons. Marſh. Can. Chron. ſec. 1. Petav. Doctrin. Temp. lib. ix. c. 14. Cumb. Orig. Gent. Antiq. p. 142—154. Uſher ad A. M. 1777 and 1787. Whiſton's View Chron. O. T.

Dr. Bryant has advanced a new hypotheſis on this ſubject, and ſupported it with his uſual acuteneſs and learning: he maintains, that the diſperſion as well as the confuſion of tongues was local, and limited to the inhabitants of the province of Babel; that the ſeparation and diſtribution recorded to have taken place in the days of Peleg, Gen. x. 25, 31, 32. which was the reſult of divine appointment, occaſioned a general migration; and that all the families among the ſons of men were concerned in it: the houſe of Shem, from which the Meſſiah was to ſpring, was particularly regarded in this diſtribution; the portion of his children was near the place of ſeparation; they in general had Aſia to their lot; as Japhet had Europe, and Ham the large continent of Africa. But the ſons of Chus would not ſubmit to the divine diſpenſation; they went off under the conduct of Nimrod, and ſeem to have been for a long time in a roving ſtate: however, at laſt they arrived at the plains of Shinar, and having ejected Aſhur and his ſons, who were placed there by divine appointment, ſeized his dominions, and laid there the foundation of a great monarchy. But afterwards fearing leſt they ſhould be divided and ſcattered abroad, they built the tower of Babel, as a land mark, to which they might repair, and probably to anſwer the purpoſes of an idolatrous temple, or high altar, dedicated to the hoſt of heaven, from which they were never long to be abſent. They only, viz. the ſons of Chus or the Cuthites, and their aſſociates from other families, who had been guilty of rebellion againſt divine authority, and of wicked ambition and tyranny, were puniſhed with the judgment of confounded ſpeech through a failure in labial utterance, and of the diſperſion recorded in Gen. x. 8, 9: in conſequence of which they ſcattered abroad from this city and tower, without any certain place of deſtination. The Cuthites invaded Egypt or the land of Mizraim, in its infant ſtate, ſeized the whole country, and held it for ſome ages in ſubjection: and they extended likewiſe to the Indies and Ganges, and ſtill farther into China and Japan. From them the province of Cuſhan or Goſhen in Egypt derived its name: here they obtained the appellation of royal ſhepherds; and when they were by force driven out of the country, after having been in poſſeſſion of it for two hundred and ſixty, or two hundred and eighty years, the land which they had been obliged to quit was given to the Iſraelites, who were alſo denominated ſhepherds, but ſhould not be confounded with the former or the antecedent inhabitants of Goſhen. Bryant's Analyſis of Ancient Mythol. vol. iii. p. 16, &c.

DISPLANTING, among gardeners, is the plucking up a tree or plant out of the ground.

DISPLAYED, in heraldry, is underſtood of the poſition of an eagle, or other bird, when it is erect, with its wings expanded, or ſpread forth.

DISPOSITION, in human nature. In every man there is ſomething original, that ſerves to diſtinguiſh him from others, that tends to form a character, and to make him meek or fiery, candid or deceitful, reſolute or timorous, cheerful or moroſe. This original bent, termed diſpoſition, muſt be diſtinguiſhed from a principle: the latter, ſignifying a law of human nature, makes part of the common nature of man; the former makes part of the nature of this or that man. Propenſity is a name common to both; for it ſignifies a principle, as well as a diſpoſition.

Diſpoſition, from *dis*, and *pono*, *I place*, in architecture, is the juſt placing of all the ſeveral parts of an edifice, according to their proper nature and office.

Diſpoſition, in logic, is that operation of the mind, whereby we put the ideas, propoſitions, and arguments which we have formed concerning one ſubject, into ſuch an order as is fitteſt to gain the cleareſt knowledge of it, to retain it longeſt, and to explain it to others in the beſt manner: the effect of this is called method. Watt's Logic.

Diſpoſition, in a military ſenſe, is the arrangement of an army, or body of men upon the moſt advantageous ground, and in the beſt ſituation for a vigorous attack or defence.

Diſpoſition, in rhetoric, is defined, by Cicero, the act of diſtributing the things, or arguments, invented or found out, into a proper order; or a due placing, or ranging, the ſeveral parts of ſpeech, or diſcourſe. The diſpoſition makes one of the great branches, or diviſions, of rhetoric.

Iſocrates was the firſt among the Greeks that made them ſenſible of the beauty of diſpoſition; and Cicero among the Romans. The diſpoſition is of the ſame neceſſity in oratory, as the marſhalling of an army in order to a battle; or a beautiful compoſition in architecture, painting, &c. Horace enjoins it expreſsly in poetry: *Singula quæque locum teneant ſortita decenter.* The diſpoſition, then, is the order, or arrangement, of the parts of an oration; which parts are uſually reckoned four, viz. the *exordium*, or *beginning*; the *narration*; the *confirmation*; and the *peroration*, or *concluſion*. Though ſome make them ſix, viz. the *exordium*, *diviſion*, *narration*, *confirmation*, *confutation*, and *peroration*; as indicated in that popular verſe:

Exorſus, narro, ſeco, firmo, refuto, peroro.

But the diviſion is moſt naturally referred to the exordium; and the confutation to the confirmation. The diſpoſition is either natural or artificial. Natural, is the order the parts are above rehearſed in. Artificial, is when, for ſome particular reaſon, we recede from the order of nature.

DISPROPORTION, a term of relation, implying a want of proportion; or ſymmetry.

DISPUTE, or **Diſputation**, from *dis*, and *puto*, *I think*, in the ſchools, &c. a conteſt, or combat, either by word or writing, on ſome point of learning or religion, for a degree, prize, exerciſe, or even for the mere ſake of a truth, or advantage of a party, or the honour of a triumph.

The Port Royaliſts take occaſion to obſerve, that nothing gives ſo many different lights and openings, for diſcovering the truth, as diſputation. The movements of a mind, employed ſingly in the examination of any ſubject, are uſually too cool and languid; the mind needs a certain degree of heat to awaken its ideas. Now, by the oppoſitions in a diſpute, we come to find wherein the difficulty lies, and the vigour the mind has acquired enables us to ſurmount it.

DISQUISITION, from *dis*, and *quæro*, *I enquire*, an enquiry into the nature, kinds, and circumſtances of any problem, queſtion, or topic; in order to gain a right notion of it, and to diſcourſe clearly about it.

DISSECTION, from *dis*, and *ſeco*, *I cut*, in anatomy, the operation of cutting and dividing the parts of an animal body, with a knife, ſciſſars, &c. in order to ſee and conſider each of them apart. The ancients made diſſections of living men; as we read of Herophilus and Eraſiſtratus; and, in our own times, of Carpus and Veſalius. Yet, Le Gendre obſerves, that the diſſection of a human body, even dead, was held a ſacrilege till the time of Francis I. And the ſame author aſſures us, he has ſeen a conſultation held by the divines of Salamanca, at the requeſt of Charles V. to ſettle the queſtion, whether or no it were lawful, in point of conſcience, to diſſect a human body, in order to learn its ſtructure.

DISSEISIN, in law, an unlawful diſpoſſeſſing a man of his land, tenement, or other immoveable and incorporeal right.

DISSEISOR, he who diſſeiſeth or puts another out of his land: as diſſeiſee is he who is put out. If a diſſeiſor, after he has expelled the right owner, gains peaceable poſſeſſion of the lands five years without claim, and continues in poſſeſſion, ſo as to die ſeiſed, and the land deſcends to his heirs, they will have a right to the poſſeſſion till the owner recovers at law; and the owner ſhall loſe his eſtate for ever, if he doth not proſecute his ſuit within the time limited by the ſtatute of limitations.

DISSENTERS, a general denomination of equal import with non-conformiſts. It expreſſes certain ſects, or parties, who, in matters of religion, church-diſcipline, and ceremonies, diſſent from, or diſagree with the church of England, and have a toleration by law for the ſame. Such, particularly, are the preſbyterians, independents, anabaptiſts, and quakers.

At the Revolution, a law was enacted, that the ſtatutes of queen Elizabeth, and king James I. concerning the diſcipline of the church, ſhould not extend to proteſtant diſſenters: but the perſons

diſſent

diſſenting are to ſubſcribe the declaration of 30 Car. II. c. 1. and take the oaths, or the declaration of fidelity, &c. And they muſt not hold their meetings until their place of worſhip is certified to the biſhop, &c. or to the juſtices at their quarter ſeſſions, and regiſtered there; alſo they are not to keep the doors of their meeting-houſes locked, &c. If any perſon diſturbs them at their worſhip, on conviction at the ſeſſions, he ſhall forfeit 20l. And there are many ſtatutes relating to diſſenters beſides the toleration act.

DISSEPIMENTUM, among botaniſts, the thin ſeptum ſeparating the cells of the fruit of plants.

DISSIDENTS, a denomination applied in Poland to thoſe of the Lutheran, Calviniſtic, and Greek profeſſion. The king of Poland engages by the *pacta conventa* to tolerate them in the free exerciſe of their religion, but they have often had reaſon to complain of the violation of theſe promiſes.

DISSIMILAR *Leaves*, denote the two firſt leaves of any plant at its firſt ſhooting out of the ground. They are thus called, becauſe they uſually are of a different form from the common leaves of a grown plant.

Dissimilar, in anatomy. Authors divide the parts of the body into ſimilar, and diſſimilar. Diſſimilar parts, by ſome called alſo compound, and organical parts, are ſuch as may be divided into various parts, of different ſtructure, &c. Thus the hand is diviſible into veins, muſcles, bones, &c. whoſe ſubdiviſions are neither of the ſame nature nor denomination.

DISSIMILITUDE, in rhetoric, &c. an argument, wherein, from diſſimilar, or unlike things, other diſſimilars are deduced.

Thus Cicero, *Si barbarorum eſt in diem vivere; noſtra conſilia ſempiternum tempus ſpectare debent.* Catullus furniſhes a very beautiful argument from diſſimilitude.

> *Soles occidere & redire poſſunt,*
> *Nobis cum ſemel occidit brevis lux,*
> *Nox eſt perpetua una dormienda.*

DISSIMULATION, in morals, the act of diſſembling, by fallacious appearances, or falſe pretenſions. Good princes regard diſſimulation as a neceſſary vice; but tyrants conſider it as a virtue. It is apparent that ſecrecy is often neceſſary, to oppoſe thoſe who may be willing to circumvent our lawful intentions.

> " Your face, my Thane, is a book where men
> " May read ſtrange matters. To beguile the time,
> " Look like the time; bear welcome in your eye,
> " Your hand your tongue; look like th' innocent flow'r
> " And be the ſerpent under't."
>
> " Shakespear."

DISSIPATION, in phyſics, an inſenſible loſs, or conſumption, of the minute parts of a body: or, more properly, that flux whereby they fly off, and are loſt.

We do not ſay diſſipation, but loſs of blood, in ſpeaking of the blood diſcharged at a wound, or in any other ſenſible manner: on the contrary, we ſay diſſipation, or expence of ſpirits; this is more copious than that of the ſolid parts: and conſequently, the reparation ought to be more copious.

Circle of Dissipation, or *Aberration*, in optics, denotes, that circular ſpace upon the retina of the eye, which is occupied by the rays of each pencil in indiſtinct viſion. See Aberration, and Syſtem of Optics.

DISSOLVENT, ſomething that diſſolves, i. e. divides, and reduces a body into its ſmalleſt parts. Thus, aqua regia is the diſſolvent of gold; aqua fortis of ſilver, and other metals; water, of ſalts and gums; ſpirits of wine, of raiſins; ſpirit of vinegar, of pearls, corals, &c. Sea ſalt is found the proper diſſolvent of gold. This, in almoſt any form, whether as a fluid, or a ſolid, or a ſpirit, does the buſineſs: accordingly, this is a baſis, or fundamental ingredient, of aqua regia. So nitre is the proper diſſolvent of ſilver, and has that effect, in whatever form it is applied: and, accordingly, it is the baſis of aqua fortis.

DISSOLUTION, in chymiſtry, pharmacy, and phyſics, a diſcontinuation, or analyſis, of the ſtructure of a mixed body; whereby, what was one, and contiguous, is divided into little parts, either homogeneous, or heterogeneous. See Analysis.

Diſſolution, then, is a general name for all reductions of concrete bodies into their ſmalleſt parts, without any regard either to ſolidity or fluidity: though, in the uſual acceptation of the word among authors, it is reſtrained to the reduction of ſolid bodies into a ſtate of fluidity, by the action of ſome fluid menſtruum or diſſolvent; in which caſe an union is formed between the integrant parts of one body, and thoſe of another of a different nature; ſo that it is nothing elſe than an act of combination: this is more properly expreſſed by ſolution, as a branch of diſſolution.

Dissolution *of Metals, &c.* by fire, is particularly called *fuſion.* See Syſtem of Chymistry, Sect. II. Part II.

Dissolution *of the Blood*, is an affection of that humour, directly oppoſite to coagulation. The diſſolution is ſuch a comminution of the fibrous parts of the blood, as indiſpoſes it for that ſeparation of the craſſamentum from the ſerous part, which always enſues in healthy blood, on its cooling out of the body. This diſſolution is frequently the conſequence of malignant and peſtilential fevers, and ſhews itſelf in petechiæ, or purple ſpots; alſo of certain poiſons, particularly the bites of venemous beaſts, &c.

Dissolution *of Parliament*. See Parliament.

DISSONANCE, or Discord, in muſic, a falſe conſonance, or concord. A diſſonance is properly the reſult of a mixture, or meeting of two ſounds, which are diſagreeable to the ear.

DISSYLLABLE, a word of two ſyllables; as fortune, lament, &c. The ſpondee, trochee, iambus, and pyrrhichius, are diſſyllabic feet.

DISTAFF, an inſtrument about which flax is tied, in order to the ſpinning of it.

DISTANCE, properly denotes the ſhorteſt line between two points, objects, &c. Diſtance, according to an ingenious author, cannot of itſelf and immediately be ſeen. For diſtance being a line directed endwiſe to the eye, it projects only one point in the fund of the eye, which point remains invariably the ſame, whether the diſtance be longer or ſhorter. Dr. Berkeley, Eſſay on Viſion.

The word is alſo uſed figuratively for an interval, not only in reſpect of place, but alſo of time, or quality. Thus, we ſay the diſtance of the creation of the world from the nativity of Jeſus Chriſt, is upwards of four thouſand years: the diſtance between the creator and the creature is infinite.

Distance, in aſtronomy. The diſtance of the ſun, planets, and comets, is found from their parallax. See Syſtem of Astronomy, Sect. VII.

Distance *of the Baſtions*, in fortification, is the ſide of the exterior polygon. See Syſtem of Fortification.

Distances, in geometry, are meaſured by the chain, decempeda, and the like.

Inacceſſible Distances, are found by taking bearings thereto from the two extremes of a line, whoſe length is given.

Distance, in geography, is the arch of a great circle interſected between two places. See Syſtem of Geography.

Apparent Distance, in optics, that diſtance which we judge an object to be from us when ſeen afar off, being commonly very different from the true diſtance: becauſe we are apt to think that all very remote objects, whoſe parts cannot well be diſtinguiſhed, and which have no other object in view near them, to be at the ſame diſtance from us, though perhaps the one is thouſands of miles nearer than the other, as is the caſe with regard to the ſun and moon. See Syſtem of Optics, and the following Works.

Accidens de la Vie, p. 358. Smith's Optics, vol. i. p. 52. and Rem. p. 51. Robins's Tracts, vol. ii. p. 230, 247, 251. Porterfield on the Eye, vol. i. p. 105, vol. ii. p. 387, &c. See Prieſtley's Hiſt. of Viſion, p. 205. and p. 689, &c.

Distance, in navigation, is the number of miles, or leagues, that a ſhip has ſailed from any point.

Line of Distance, in perſpective, is a right line drawn from the eye to the principal point. See Syſtem of Perspective.

Point of Distance, in perſpective, is a point in the horizontal line at ſuch diſtance from the principal point, as is that of the eye from the ſame.

DISTASTE, or Disgust, a loſs of appetite, or an averſion, or repugnance, to foods which are commonly eaten. Diſtaſte is held, by phyſicians, one of the principal diſorders of the ſtomach. It ariſes from a want of ſenſation in the upper orifice of the ventricle, which may be occaſioned various ways: as by a too great abundance of food; thick, heavy humours in the ſtomach: fat viſcid aliment; obſtructions of the lacteals: ſuppreſſions of the uſual evacuations; intermiſſions of the ordinary exerciſes, a defect of the nerves, in having their natural faculty aboliſhed, or ſuſpended as in a lethargy, and apoplexy; and according to Sylvius, by a groſs viſcid ſaliva, or a thick bile, aſcending out of the ſmall guts into the ſtomach.

DISTEMPER, in medicine. See Disease.

Distemper is uſed in painting, for the working up of colours with ſomething elſe beſides bare water, or oil. If the colours be prepared with the former of theſe, that kind of painting is called limning; and if with oil, it is called painting in oil, or ſimply painting. If the colours be mixed with ſize, whites of eggs, or any ſuch proper glutinous, or unctuous ſubſtance, and not with oil, they then ſay, it is done in diſtemper; as thoſe of the admirable cartoons, formerly at Hampton court.

DISTENSION, the act of ſtretching a thing; alſo the ſtate of a thing violently ſtretched, and diſtended.

DISTICH, Διςιχον, a couplet of verſes; or a piece of poetry, the ſenſe whereof is comprehended in two lines. There are excellent morals in Cato's Diſtichs. See Vigneul de Marville on the Diſtichs of Cato, tom. i. p. 54, 55. Hexameter and pentameter verſes, otherwiſe called elegiacs, are diſpoſed in diſtichs.

DISTICHIASIS, in medicine, a diſorder of the eye lids; wherein, inſtead of one, they have two rows of cilia, or hairs. The word is formed of δις, *twice*, and ςιχος, or ςοιχος, *order*, *rank*. In the diſtichiaſis, over the common, and natural hairs, there grows another extraordinary row, which frequently eradicates, and tears up the former; and, pricking the membrane immediately inveſting the eye, occaſions pain, and draws defluxions upon it. It is cured by plucking up the ſecond rows of hairs with nippers, and cauteriſing the pores out of which they iſſued.

TREATISE ON DISTILLATION.

DISTILLATION: the objects of diſtillation, conſidered as a trade diſtinct from the other branches of chymiſtry, are chiefly ſpirituous liquors, and thoſe waters impregnated with the eſſential oils of plants, commonly called *ſimple diſtilled* waters. The diſtilling compound ſpirits and waters is reckoned a different branch of buſineſs, and they who deal in that way are commonly called *rectifiers*. This difference, however, though it exiſts among commercial people, is not at all founded in the nature of the thing; compound ſpirits being made, and ſimple ſpirits being rectified, by the very ſame operations by which they are at firſt diſtilled, or at leaſt with very trifling alterations.

Spirit perfectly flavourleſs, how obtained.

The great object with every diſtiller ought to be to procure a ſpirit perfectly flavourleſs, or at leaſt as well freed from any particular flavour as may be; and in this country the procuring of ſuch a ſpirit is no eaſy matter. The only materials for diſtillation that have been uſed in large quantity, are malt and molaſſes or treacle. Both of theſe, eſpecially the firſt, abound with an oily matter, which riſing along with the ſpirit, communicates a diſagreeable flavour to it, and from which it can ſcarce be freed afterwards by any means whatever. Some experiments have been made upon carrots, as a ſubject for the diſtillers: but theſe are not as yet ſufficiently deciſive; nor is it probable, that a ſpirit drawn from carrots would be at all devoid of flavour, more than one drawn from malt. To diſſipate the eſſential oil which gives the diſagreeable flavour to malt ſpirits, it has been propoſed to inſpiſſate the wort into a rob, or thin extract like a ſyrup; afterwards to thin it with water, and ferment it in the uſual manner. This certainly promiſes great ſueceſs; there is no ſubject we know of that is poſſeſſed of any kind of eſſential oil, but what will part with it by diſtillation, or by long boiling. The inſpiſſating of the wort, however, does not ſeem to be either neceſſary, or ſafe to to be attempted; for, in this caſe, there is great danger of its contracting an empyreuma, which never could be remedied. The quantity loſt by evaporation, therefore, might be occaſionally added, with an equal certainty of diſſipating the obnoxious oil. Whether the yield of ſpirit would be as great in this caſe as in the other, is a queſtion that can by no means be diſcuſſed without further experiments.

Eſſential Oil by ſome thought convertible into Spirit.

According to the theory adopted by ſome diſtillers, namely, that eſſential oils are convertible into ardent ſpirits; and that the more oily any ſubject is, the greater quantity of ſpirit is obtainable from it; the practice of diſſipating the oil before fermentation muſt certainly be a loſs. But we are too little acquainted with the compoſition of vinous ſpirits, to have any juſt foundation for adopting ſuch theories. Beſides, it is certain, that the quantity of ardent ſpirit producible from any ſubſtance, malt for inſtance, very greatly exceeds the quantity of eſſential oil which can by any means be obtained from the ſame; nor do we find that thoſe ſubſtances, which abound moſt in eſſential oil, yield the greateſt quantity of ſpirits. So far from this, fine ſugar, which contains little or no eſſential oil, yields a great deal of ardent ſpirit.

Directions concerning Fermentation.

Previous to the operation of diſtilling, thoſe of brewing and fermentation are neceſſary; but as theſe are fully treated of under the article BREWING, we ſhall here only obſerve, that unleſs the boiling of the wort, before fermentation, is found to diſſipate the eſſential oil, ſo as to take away the flavour of the malt, there is no neceſſity for being at the trouble of that operation. The wort may be immediately cooled and fermented. The fermentation ought always to be carried on as ſlowly as poſſible, and performed in veſſels cloſely ſtopped; only having at the bung a valve preſſed down by a ſpring, which will yield with leſs force than is ſufficient to burſt the veſſel. It ſhould even be ſuffered to remain till it has become perfectly fine and tranſparent; as by this means the ſpirit will not only be ſuperior in quantity, but alſo in fragrance, pungency, and vinoſity, to that commonly produced.

For Diſtillation.

With regard to performing the operation of diſtilling, there is only one general rule that can be given; namely, to let the heat, in all caſes, be as gentle as poſſible. Accidents will be effectually prevented by having the worm of a proper wideneſs, and by rectifying the ſpirits in a water bath; which, if ſufficiently large, will perform the operation with all the diſpatch requiſite for the moſt extenſive buſineſs. The veſſel in which the rectification is performed, ought to be covered with water up to the neck, and to be loaded with lead at the bottom, ſo that it may ſink in the water. Thus the operation will go on as quickly as if it was on an open fire, and without the leaſt danger of a miſcarriage; nor will it ever be neceſſary to make the water in the bath come to a boilling heat.

Combinatory Diſtillation, is a term introduced into uſe by Dr. Shaw, in his eſſay on diſtillation, to expreſs that ſort of rectification of diſtilled ſpirits which is done with additions, and which he otherwiſe calls improper rectification by way of diſtinction from that proper rectification, which is the only method of reducing a ſpirit to its utmoſt degree of purity and perfection.

In the combinatory diſtillation, many ingredients are added in order to rectify the ſpirit, as the diſtillers expreſs it; and ſome part of theſe actually come over and mix themſelves along with the ſpirit ſo intimately, as not to be ſeparable again without great difficulty. This is done with a deſign to alter, improve, or aboliſh the natural flavour of the ſpirit; but inſtead of rectifying it, they only obſcure and pervert its true qualities. In the buſineſs of rectification, properly ſo called, of the malt ſpirit, all that is neceſſary is the re-diſtilling of the low wines procured from the waſh; the again diſtilling over of the ſpirit thus obtained, and called proof ſpirit, into a totally inflammable liquor called alcohol. This is done by the common proceſſes, only taking care not to increaſe the fire by ſudden ſpurts, ſo as to raiſe the oil with the ſpirit, which if once mixed, will not be eaſily ſeparated again, and ſcarce ever perfectly, whatever care is uſed.

For Rectification.

As the end of rectification is to make the ſpirit clean as well as ſtrong, or to deprive it of the eſſential oil as well as the aqueous part, it will be proper to have regard to this even in the firſt diſtillation. For this purpoſe, the ſpirit, as it firſt comes over, ſhould be received into a quantity of cold water; as by this means the connection betwixt it and the oily matter will be conſiderably leſſened. For the ſame reaſon, after it has been once rectified in the water bath, it ſhould be again mixed with an equal quantity of water, and diſtilled a ſecond time. Thus the ſpirit will be freed from moſt of the oily matter, even though it hath been very much impregnated with it at firſt. It is neceſſary to obſerve, however, that by uſing ſuch a quantity of water, a conſiderable part of the ſpirit will be left in the reſiduum of each rectification. All theſe reſiduums, therefore, muſt be mixed together, and diſtilled on an open fire, with a briſk heat, that the remainder of the ſpirit may be got out.

After the ſpirit has been diſtilled once or twice in this manner from water, it may be diſtilled in a water bath without any addition; and this laſt rectification will free it from moſt of the water it contains. But if it is required to be highly dephlegmated, a quantity of pure and dry ſalt of tartar muſt be added. The attraction betwixt this ſalt and water is greater than that betwixt water and ſpirit of wine: The ſalt therefore imbibes the water contained in the ſpirit, and ſinks with it to the bottom. The ſpirit, by a ſingle diſtillation, may then be rendered perfectly free from water; but there is great danger of ſome of the alkaline ſalt riſing along with it, and impregnating it with what is called an urinous flavour. When this once happens, it is impoſſible to be remedied; and the only way to prevent it, is to make the heat with which the ſpirit is diſtilled as gentle as poſſible. It hath been propoſed, indeed, to prevent the riſing of any thing alkaline, by the admixture of ſome calcined vitriol, ſal catharticus amarus, or other imperfect neutral ſalt; but this can ſcarce be ſuppoſed to anſwer any good purpoſe, as the alkali unites itſelf with the oily matter of the ſpirit, and forms a kind of ſaponaceous compound, which is not ſo eaſily affected by the acid of vitriol or other ſalt, eſpecially as theſe ſalts will not diſſolve in the ſpirit itſelf.

The Methods of Combinatory Rectification are very numerous, every diſtiller having his peculiar noſtrum. Malt ſpirit is the general ſubject of this proceſs, and the means uſed to rectify it on this plan may be reduced to three heads. 1. That by fixed alkaline ſalt alone. 2. That by fixed alkaline ſalts and acid ſpirits. And 3. That by ſaline bodies and flavouring additions.

The general method is that by fixed alkaline ſalts alone; but it is ſurpriſing to ſee in how careleſs and ſlovenly a manner this is done by the generality of our diſtillers, though we are allowed to excel all other nations in it. The effect of this operation, when carefully performed, is to attenuate and thin the ſpirit, and to keep back a part of its groſs and fœtid oil, and ſo far to alter the part of the oil which comes over, as ſcarce to leave the ſpirit diſtinguiſhable for a malt ſpirit. This end is greatly promoted by a prudent and ſteady management of the fire, and by leaving out the faints; but this is a thing our diſtillers never attend to: they hurry over the operation, working the ſtill in its full force, and by this means raiſe and carry over the oil; though the whole buſineſs of the proceſs is to keep it back; and they even ſuffer the fulſome bitter oil, made into a kind of liquid ſoap with the ſalt in this proceſs, to run among the ſpirit with the faints; by this the whole intent of the proceſs is fruſtrated, and the ſpirit rendered much harder to clean than it was before.

This operation is uſually performed upon proof-ſpirit, and the quantity allowed is from eight to fourteen pounds of ſalt of tartar, fixed nitre, pot-aſh, or more commonly calcined tartar, to the piece. The tartar being only roaſted to a blackneſs in this laſt proceſs, is ſold under the abſurd notion of a vinous ſalt; and the dealers will often praiſe the vinoſity of their ſpirit, becauſe diſtilled from this ſalt: but the truth is, that this ſalt never fails to give, inſtead of a vinoſity, a ſaponaceous, urinous, or lixivial taſte and ſmell. This is the great misfortune that attends the method of rectifying by means of fixed ſalt, for they all of them become volatile in part during the operation; and this volatile portion paſſes over the helm with the ſpirit, and impregnates it, uniting itſelf alſo with that portion of oil yet retained in the ſpirit, and much more firmly combining it and the ſpirit together than they were before; ſo that in reality the ſpirit thus rectified is no other than an alkaline or tartariſed ſpirit, as the chymiſts call it, a thing extremely different from a true vinous ſpirit.

This method, therefore, though it were practiſed to the utmoſt perfection, would never do what was intended by it, but would alter, inſtead of rectifying the ſpirit. Hence there appears the neceſſity of ſome acid to deaden the force of the alkali thus uſed in the rectification. The neceſſity of this, gave occaſion to the method of mixing acids and alkalis together for theſe purpoſes. The acids uſed by our diſtillers on this occaſion, are thoſe of the mineral kingdom, becauſe of their cheapneſs; and the moſt common in uſe among them are oil of vitriol, ſpirit of nitre, oil of ſulphur, and the like. The moſt celebrated rectifiers in the malt way have got their reputation by the uſe of theſe acids. There is ſome choice, however, to be made of the ſpirits according to the greater or leſſer foulneſs and need of rectification, and they muſt not only be well proportioned, but carefully introduced, and regularly mixed; and indeed without ſome ſkill and judgment in the management of theſe corroſives, no diſtiller ought to attempt to meddle with them.

Theſe ſtrong and violent acids at beſt are not ſo well adapted to the work as the milder ones, particularly the ſulphureous ſpirit of vitriol, which comes over in the rectification of the oil; to this may be added the common *ſpiritus nitri dulcis*, and Mr. Boyle's acid ſpirit of wine well prepared.

Some of our rectifiers, inſtead of this ſalt, uſe quick-lime, which cleanſes and dephlegmates conſiderably: but this method requires the aſſiſtance of acids alſo afterwards, to take off not only the alkaline diſpoſition, but alſo the ſtinking flavour it leaves behind it. Some alſo uſe chalk, virgin earth calcined, and burnt animals bones. Theſe are of conſiderable uſe in the rectifying of brandy without rendering the ſpirit any more unfit for the purpoſe of the compounders than before, or requiring much acid afterwards.

The ultimate perfection aimed at in all the proceſſes of combinatory diſtillation, is the depurating of the Engliſh malt ſpirit at one operation, ſo as to render it taſteleſs and inordorous, and yet vinous; or elſe to make it reſemble the French brandy, arrack, or ſome other low flavoured vinous ſpirits.

This is certainly practicable, though not uſually practiſed to the perfection that it might be: the principal thing to be endeavoured after, is the obtaining of a taſteleſs ſpirit, capable of receiving any impreſſion, and then the buſineſs of flavouring is eaſy. The method of rectifying, by fixed alkaline ſalts, is capable of great improvement, as by ſteeping the ſpirit firſt brought near to the ſtate of alcohol, upon a well dried ſalt of tartar, or any other cheaper, but pure fixed alkali; by this means it will be almoſt totally freed of its oil without volatiliſing much of the ſalt, as it does in the way of diſtillation; by this means a weak tincture of ſalt of tartar may be procured, and an acid added to this, to take off the effects of the alkali in the ſpirit; the whole is then to be diſtilled, and the fire being well managed, a very clean ſpirit will be thus procured at one operation, ſuch as can no way elſe be obtained at once.

Of Imitating Foreign Spirits.

One very great deſideratum among the diſtillers of this country, is a method of imitating the foreign ſpirits, brandy, rum, gin, &c. to a tolerable degree of perfection; and notwithſtanding the many attempts that are daily made for this purpoſe, the ſucceſs in general hath been but very indifferent. One of the lateſt, Mr. Cooper hath the following obſervations, in his "Complete Syſtem of Diſtillation;" which, as they are applicable to all other ſpirits a well as brandy, we ſhall here tranſcribe.

Method of making Brandies in France.

" The general method of diſtilling brandies in France need not be formally deſcribed, as it differs in nothing from that practiſed here in working from malt waſh, or molaſſes; nor are they in the leaſt more cleanly or exact in the operation. They only obſerve more particularly to throw in a little of the natural ley into the ſtill along with the wine, as finding this gives their ſpirit the flavour for which it is generally admired abroad. But, though brandy is extracted from wine, experience tells us that there is a great difference in the grapes from which the wine is made. Every ſoil, every climate, every kind of grapes, varies with regard to the quantity and quality of the ſpirits extracted from them. There are ſome grapes which are only fit for eating; others for drying, as thoſe of Damaſcus, Corinth, Provence, and Avignon, but not fit to make wine. Some wines are very proper for diſtillation, and others much leſs ſo. The wines of Languedoc and Provence afford a great deal of brandy by diſtillation, when the operation is performed on them in their full ſtrength. The Orlean wines, and thoſe of Blois, afford yet more: but the beſt are thoſe of the territories of Cogniac and Andaye; which are, however, in the number of thoſe the leaſt drank in France. Whereas thoſe of Burgundy and Champagne, though of a very fine flavour, are improper, becauſe they yield but very little in diſtillation.

" It muſt alſo be farther obſerved, that all the wines for diſtillation, as thoſe of Spain, the Canaries, of Alicant, of Cyprus, of St. Peres, of Toquet, of Grave, of Hungary, and others of the ſame kind, yield very little brandy by diſtillation; and conſequently would coſt the diſtiller conſiderably more than he could ſell it for. What is drawn from them is indeed very good, always retaining the ſaccharine quality and rich flavour of the wine from whence it is drawn; but as it grows old, this flavour often becomes aromatic, and is not agreeable to all palates.

" Hence we ſee that brandies always differ according as they are extracted from different ſpecies of grapes. Nor would there be ſo great a ſimilarity as there is between the different kinds of French brandies, were the ſtrongeſt wines uſed for this purpoſe: but this is rarely the caſe: the weakeſt and loweſt flavoured wines only are diſtilled for their ſpirit, or ſuch as prove abſolutely unfit for any other uſe.

" A large quantity of brandy is diſtilled in France during the time of the vintage; for all thoſe poor grapes that prove unfit for wine, are uſually firſt gathered, preſſed, their juice fermented, and directly diſtilled. This rids their hands of their poor wines at once, and leaves their caſks empty for the reception of better. It is a general rule with them not to diſtil wine that will fetch any price as wine; for, in this ſtate, the profits upon them are vaſtly greater than when reduced to brandies. This large ſtock of ſmall wines, with which they are almoſt over-run in France, ſufficiently accounts for their making ſuch vaſt quantities of brandy in that country, more than in others which lie in warmer climates and are much better adapted to the production of grapes. Nor is this the only fund of their brandies; for all the wine that turns eager, is alſo condemned to the ſtill; and, in ſhort, all that they can neither export nor conſume at home, which amounts to a large quantity: ſince much of the wine laid in for their family proviſion is ſo poor as not to keep during the time of ſpending.

How Brandy may be imitated in this Country.

" Hence many of our Engliſh ſpirits, with proper management, are convertible into brandies that ſhall hardly be diſtinguiſhed from the foreign in many reſpects, provided the operation be neatly performed.

" The common method of rectifying ſpirits from alkaline ſalts, deſtroys their vinoſity, and in its ſtead introduces an urinous or lixivious taſte. But as it is abſolutely neceſſary to reſtore, or at leaſt to ſubſtitute in its room, ſome degree of vinoſity, ſeveral methods have been propoſed, and a multitude of experiments performed, in order to diſcover this great deſideratum. But none has ſucceeded equal to the ſpirit of nitre; and accordingly this ſpirit, either ſtrong or dulcified, has been uſed by moſt diſtillers to give an agreeable vinoſity to their ſpirits. Several difficulties, however, occur in the method of uſing it; the principal of which is, its being apt to quit the liquor in a ſhort time, and conſequently depriving the liquor of that vinoſity it was intended to give. In order to remove this difficulty, and prevent the vinoſity from quitting the goods, the dulcified ſpirit of nitre, which is much better than the ſtrong ſpirit, ſhould be prepared by a previous digeſtion, continued for ſome time, with alkohol; the longer the digeſtion is continued, the more intimately will they be blended, and the compound rendered the milder and ſofter.

" After a proper digeſtion, the dulcified ſpirit ſhould be mixed with the brandy, by which the vinoſity will be intimately blended with the goods, and not diſpoſed to fly off for a very conſiderable time. No general rule can be given for the quantity of this mineral acid requiſite to be employed; becauſe different proportions of it are neceſſary in different ſpirits. It ſhould, however, be carefully attended to, that though a ſmall quantity of it will undoubtedly give an agreeable vinoſity reſembling that naturally found in the fine ſubtile ſpirit drawn from wines, yet an over large doſe of it will not only cauſe a diſagreeable flavour, but alſo render the whole deſign abortive, by diſcovering the impoſition. Thoſe, therefore, who endeavour to cover a foul taſte in goods by large doſes of dulcified ſpirit of nitre, will find themſelves deceived.

" But the beſt, and indeed the only method of imitating French brandies to perfection, is by an eſſential oil of wine; this being the very thing that gives the French brandies their flavour. It muſt, however, be remembered, that in order to uſe even this ingredient to advantage, a pure taſteleſs ſpirit muſt firſt be procured; for it is ridiculous to expect that this eſſential oil ſhould be able to give the agreeable flavour of French brandies to our fulſome malt ſpirit, already loaded with its own nauſeous oil, or ſtrongly impregnated with a lixivious taſte from the alkaline ſalts uſed in rectification. How a pure inſipid ſpirit may be obtained, has already been conſidered; it only therefore remains to ſhew the method of procuring this eſſential oil of wine, which is this:

" Take ſome cakes of dry wine lees, ſuch as are uſed by our hatters, diſſolve them in ſix or eight times their weight of water, diſtil the liquor with a ſlow fire, and ſeparate the oil with a ſeparating glaſs; reſerving for the niceſt uſes only that which comes over firſt, the ſucceeding oil being coarſer and more reſinous. Having procured this fine oil of wine, it may be mixed into a quinteſſence with pure alcohol; by which means it may be preſerved a long time fully poſſeſſed of all its flavour and virtues; but, without ſuch management it will ſoon grow reſinous and rancid.

" When a fine eſſential oil of wine is thus procured, and alſo a pure and inſipid ſpirit, French brandies may be imitated to perfection,

fection, with regard to the flavour. It muſt however be remembered, and carefully adverted to, that the eſſential oil be drawn from the ſame kind of lees as the brandy to be imitated was procured from; we mean, in order to imitate Coniac brandy, it will be neceſſary to diſtil the eſſential oil from Coniac lees; and the ſame for any other kind of brandy. For, as different brandies have different flavours, and as theſe flavours are entirely owing to the eſſential oil of the grape, it would be prepoſterous to endeavour to imitate the flavour of Coniac brandy with an eſſential oil procured from the lees of Bourdeaux wine. When the flavour of the brandy is well imitated by a proper doſe of the eſſential oil, and the whole reduced into one ſimple and homogeneous fluid, other difficulties are ſtill behind: the flavour, though the eſſential part, is not, however, the only one; the colour, the proof, and the ſoftneſs, muſt alſo be regarded, before a ſpirit that perfectly reſembles brandy can be procured. With regard to the proof, it may be eaſily hit, by uſing a ſpirit rectified above proof; which, after being intimately mixed with the eſſential oil of wine, may be let down to a proper ſtandard with fair water. And the ſoftneſs may, in a great meaſure, be obtained by diſtilling and rectifying the ſpirit with a gentle fire; and what is wanting of this criterion in the liquor when firſt made, will be ſupplied by time: for it muſt be remembered, that it is time alone that gives this property to French brandies; they being at firſt acrid, foul, and fiery. But, with regard to the colour, a particular method is required to imitate it to perfection.

Spirits how coloured.

“ The art of colouring ſpirits owes its riſe to obſervations on foreign brandies. A piece of French brandy that has acquired by age a great deal of ſoftneſs and ripeneſs, is obſerved, at the ſame time, to have acquired a yellowiſh brown colour; and hence our diſtillers have endeavoured to imitate this colour in ſuch ſpirits as are intended to paſs for French brandy. And in order to this, a great variety of experiments have been made on different ſubſtances. But in order to know a direct and ſure method of imitating this colour to perfection, it is neceſſary we ſhould be informed whence the French brandies themſelves acquire their colour. This diſcovery is very eaſily made. The common experiment of trying whether brandy will turn blackiſh with a ſolution of iron, ſhews that the colour is owing to ſome of the reſinous matter of the oak caſk diſſolved in the ſpirit. There can be no difficulty, therefore, in imitating this colour to perfection. A ſmall quantity of the extract of oak, or the ſhavings of that wood, properly digeſted, will furniſh us with a tincture capable of giving the ſpirit any degree of colour required. But it muſt be remembered, that as the tincture is extracted from the caſk by brandy, that is, alcohol and water, it is neceſſary to uſe both in extracting the tincture; for each of theſe diſſolves different parts of the wood. Let, therefore, a ſufficient quantity of oak ſhavings be digeſted in ſtrong ſpirit of wine, and alſo at the ſame time other oak ſhavings be digeſted in water; and when the liquors have acquired a ſtrong tincture from the oak, let both be poured off from the ſhavings into different veſſels, and both placed over a gentle fire till reduced to the conſiſtence of treacle. In this condition let the two extracts be intimately mixed together; which may be effectually done by adding a ſmall quantity of loaf ſugar, in fine powder, and rubbing the whole well together. By this means a liquid eſſential extract of oak will be procured, and always ready to be uſed as occaſion ſhall require.

“ There are other methods in uſe for colouring brandies; but the beſt, beſides the extract of oak above mentioned, are treacle and burnt ſugar. The treacle gives the ſpirits a fine colour, nearly reſembling that of French brandy; but as its colour is but dilute, a large quantity muſt be uſed: this is not, however, attended with any bad conſequences; for notwithſtanding the ſpirit is really weakened by this addition, yet the bubble proof, the general criterion of ſpirits, is greatly mended by the tenacity imparted to the liquor by the treacle. The ſpirit alſo acquires from the mixture a ſweetiſh or luſcious taſte, and a fullneſs in the mouth; both which properties render it very agreeable to the palates of the common people, who are, in fact, the principal conſumers of theſe ſpirits. A much ſmaller quantity of burnt ſugar than of treacle will be ſufficient for colouring the ſame quantity of ſpirits: the taſte is alſo very different; for inſtead of the ſweetneſs imparted by the treacle, the ſpirit acquires from the burnt ſugar an agreeable bitterneſs, and by that means recommends itſelf to nicer palates, which are offended with a luſcious ſpirit. The burnt ſugar is prepared by diſſolving a proper quantity of ſugar in a little water, and ſcorching it over the fire till it acquires a black colour. Either treacle or burnt ſugar will nearly imitate the genuine colour of old French brandy; but neither of them will ſucceed when put to the teſt of the vitriolic ſolution.

“ The ſpirit diſtilled from molaſſes or treacle is very clean or pure. It is made from common treacle diſſolved in water, and fermented in the ſame manner as the waſh for the common malt ſpirit. But if ſome particular art is not uſed in diſtilling this ſpirit, it will not prove ſo vinous as malt ſpirit, but more flat and leſs pungent and acid, though otherwiſe much cleaner taſted, as its eſſential oil is of a much leſs offenſive flavour. Therefore, if good freſh wine lees, abounding in tartar, be added and duly fermented with the molaſſes, the ſpirit will acquire a much greater vinoſity and briſkneſs, and approach much nearer to the nature of foreign ſpirits. Where the molaſſes ſpirit is brought to the common proof ſtrength, if it is found not to have a ſufficient vinoſity, it will be very proper to add ſome good dulcified ſpirit of nitre; and if the ſpirit be clean worked, it may, by this addition only, be made to paſs on ordinary judges for French brandy. Great quantities of this ſpirit are uſed in adulterating foreign brandy, rum, and arrack. Much of it is alſo uſed alone in making cherry brandy, and other drams by infuſion; in all which many, and perhaps with juſtice, prefer it to foreign brandies. Molaſſes, like all other ſpirits, is entirely colourleſs when firſt extracted; but diſtillers always give it as nearly as poſſible the colour of foreign ſpirits.”

Rum how imitated.

If theſe principles hold good, the imitation of foreign ſpirits of all kinds muſt be an eaſy matter. It will only coſt the procuring of ſome of thoſe ſubſtances from which the ſpirit is drawn; and diſtilling this with water, the eſſential oil will always give the flavour deſired. Thus, to imitate Jamaica rum, it will only be neceſſary to procure ſome of the tops, or other uſeleſs parts, of the ſugar-canes; from which an eſſential oil being drawn, and mixed with clean molaſſes ſpirit, will give it the true flavour. The principal difficulty muſt lie in procuring a ſpirit totally, or nearly, free of all flavour of its own. The ſpirit drawn from the refuſe of a ſugar-houſe is by our author commended as ſuperior to that drawn from molaſſes; though even this is not entirely devoid of ſome kind of flavour of its own; nor indeed is that drawn from the beſt refined ſugar entirely flavourleſs. It is very probable, therefore, that to procure an abſolutely flavourleſs ſpirit is impoſſible. The only method, therefore, of imitating foreign ſpirits, is by chooſing ſuch materials as will yield a ſpirit flavoured as much like them as poſſible. The materials moſt recommended by our author in this caſe, and probably the beſt that can be uſed are raiſins. Concerning theſe he gives the following directions.

“ In order to extract this ſpirit, the raiſins muſt be infuſed in a proper quantity of water, and fermented in the manner already directed. When the fermentation is completed, the whole is to be thrown into the ſtill, and the ſpirit extracted by a ſtrong fire. The reaſon why we here direct a ſtrong fire is, becauſe by that means a greater quantity of the eſſential oil will come over the helm with the ſpirit, which will render it fitter for the diſtiller's purpoſe; for this ſpirit is commonly uſed to mix with common malt goods; and it is ſurpriſing how far it will go in this reſpect, ten gallons of it being often ſufficient to give a determining flavour and agreeable vinoſity to a whole piece of malt ſpirits.

“ It is therefore well worth the diſtiller's while to endeavour at improving the common method of extracting ſpirits from raiſins; and perhaps the following hint may merit attention When the fermentation is completed, and the ſtill charged with fermented liquor as above directed, let the whole be drawn off with as briſk a fire as poſſible; but, inſtead of the caſk or can generally uſed by diſtillers for a receiver, let a large glaſs, called by chymiſts a ſeparating glaſs, be placed under the noſe of the worm, and a common receiver applied to the ſpout of the ſeparating glaſs: by this means the eſſential oil will ſwim upon the top of the ſpirit, or rather low wine, in the ſeparating glaſs, and may be eaſily preſerved at the end of the operation. The uſe of this limpid eſſential oil is well known to diſtillers; for in this reſides the whole flavour, and conſequently may be uſed to the greateſt advantage in giving that diſtinguiſhing taſte and true vinoſity to the common malt ſpirits. After the oil is ſeparated from the low-wine, the liquor may be rectified in balneo mariæ into a pure and almoſt taſteleſs ſpirit, and therefore well adapted to make the fineſt compound cordials, or to imitate or mix with the fineſt French brandies, arracks, &c. In the ſame manner a ſpirit may be obtained from cyder. But as its particular flavour is not ſo deſirable as that obtained from raiſins, it ſhould be diſtilled in a more gentle manner, and carefully rectified according to the directions we have already given.”

Directions for diſtilling Compound Spirits.

Theſe directions may ſuffice for the diſtillation of any kind of ſimple ſpirits. The diſtillation of compound ones depends on the obſervation of the following general rules, which are very eaſy to be learned and practiſed.

1. The artiſt muſt always be careful to uſe a well cleanſed ſpirit, or one freed from its own eſſential oil. For, as a compound water is nothing more than a ſpirit impregnated with the eſſential oil of the ingredients, it is neceſſary that the ſpirit ſhould have depoſited its own.

2. Let the time of previous digeſtion be proportioned to the tenacity of the ingredients, or the ponderoſity of their oil.

3. Let the ſtrength of the fire alſo be proportioned to the ponderoſity of the oil intended to be raiſed with the ſpirit.

4. Let only a due proportion of the fineſt parts of the eſſential oil be united with the ſpirit: the groſſer and leſs fragrant parts of the oil not giving the ſpirit ſo agreeable a flavour, and at the ſame time rendering it unſightly. This may in a great meaſure be effected by leaving out the faints, and making up to proof with fine ſoft water in their ſtead.

A careful obſervation of theſe four rules will render this part of diſtillation much more perfect than it is at preſent. Nor will there be any occaſion for the uſe of burnt alum, white of eggs, iſinglaſs, &c. to fine down cordial waters; for they will preſently be fine, ſweet and pleaſant taſted, without any further trouble. We ſhall now ſubjoin particular receipts for making ſome of thoſe compound waters, or ſpirits, that are moſt commonly to be met with, and are in the moſt general eſtimation.

Receipts for a Number of Compound Spirits.

Strong Cinnamon Water. Take eight pounds of fine cinnamon bruiſed, 17 gallons of clean rectified ſpirit, and two gallons of water. Put them into your ſtill, and digeſt them 24 hours with a gentle heat; after which draw off 16 gallons with a pretty ſtrong heat. A cheaper ſpirit, but of an inferior quality, may be obtained, by uſing caſſia lignea inſtead of cinnamon. If you would dulcify your cinnamon water, take double-refined ſugar in what quantity you pleaſe; the general proportion is about two pounds to a gallon; and diſſolve it in the ſpirit, after you have made it up proof with clean water. One general caution is here neceſſary to be added; namely, that near the end of the operation, you carefully watch the ſpirit as it runs into the receiver, in order to prevent the faints from mixing with the goods. This you may diſcover by often catching ſome of it as it runs from the worm in a glaſs, and obſerving whether it is fine and tranſparent; for as ſoon as ever the faints begin to riſe, the ſpirit will have an azure or bluiſh caſt. As ſoon as this alteration in colour is perceived, the receiver muſt be immediately changed; for if the faints are ſuffered to mix themſelves with the reſt, the value of the goods will be greatly leſſened. Here we may obſerve, that the diſtillers call ſuch goods as are made up proof, double goods; and thoſe below proof, ſingle.

Clove Water. Take of cloves bruiſed, four pounds; pimento, or all-ſpice, half a pound; proof ſpirit, 16 gallons. Digeſt the mixture 12 hours in a gentle heat, and then draw off 15 gallons with a pretty briſk fire. The water may be coloured red, either by a ſtrong tincture of cochineal, alkanet, or corn-poppy flowers. It may be dulcified at pleaſure with double-refined ſugar.

Lemon Water. Take of dried lemon peel, four pounds; clean proof ſpirit 10 gallons and a half, and one gallon of water. Draw off 10 gallons by a gentle fire, and dulcify with fine ſugar.

Citron Water. Take of dry yellow rhinds of citrons, three pounds; of orange-peel, two pounds; nutmegs bruiſed, three quarters of a pound; clean proof-ſpirit, ten gallons and a half; water, one gallon: digeſt with a gentle heat; then draw off ten gallons in balneo mariæ, and dulcify with fine ſugar.

Aniſeed Water. Take of aniſeed bruiſed, two pounds; proof-ſpirit, twelve gallons and a half; water, one gallon: draw off ten gallons with a moderate fire. This water ſhould never be reduced below proof; becauſe the large quantity of oil with which it is impregnated, will render the goods milky and foul when brought down below proof. But if there is a neceſſity for doing this, their tranſparency may be reſtored by filtration.

Orange Water. Take of the yellow part of freſh orange-peels, five pounds; clean proof ſpirit, ten gallons and a half; water, two gallons: draw off ten gallons with a gentle fire.

Cedrat Water. The cedrat is a ſpecies of citron, and very highly eſteemed in Italy where it grows naturally. The fruit is difficult to be procured in this country; but as the eſſential oil is often imported from Italy, it may be made with it according to the following receipt. Take of the fineſt loaf-ſugar reduced to powder, a quarter of a pound; put it into a glaſs mortar, with 120 drops of the eſſence of cedrat; rub them together with a glaſs peſtle; and put them into a glaſs alembic, with a gallon of fine proof-ſpirits and a quart of water. Place the alembic in balneo mariæ, and draw off one gallon, or till the faints begin to riſe; and dulcify with fine ſugar. This is reckoned the fineſt cordial yet known; it will therefore be neceſſary to be particularly careful that the ſpirit is perfectly clean, and, as much as poſſible, freed from any flavour of its own.

Ros Solis. Take of the herb called ros ſolis, picked clean, four pounds; cinnamon, cloves, and nutmegs, of each three ounces and a half; marigold-flowers, one pound; caraway-ſeeds, ten ounces; proof-ſpirit, ten gallons; water, three gallons. Diſtill with a pretty ſtrong fire, till the faints begin to riſe. Then take of liquorice root ſliced, half a pound; raiſins ſtoned, two pounds; red ſaunders, half a pound: digeſt theſe three days in two quarts of water; then ſtrain out the clear liquor, in which diſſolve three pounds of fine ſugar, and mix it with the ſpirit drawn by diſtillation.

Uſquebaugh. Take of nutmegs, cloves, and cinnamon, of each two ounces; of the ſeeds of aniſe, caraway, and coriander, of each four ounces; liquorice-root ſliced, half a pound. Bruiſe the ſeeds and ſpices; and put them, together with the liquorice, into the ſtill with 11 gallons of proof ſpirits, and two gallons of water. Diſtill with a pretty briſk fire till the faints begin to riſe. But, as ſoon as the ſtill begins to work, faſten to the noſe of the worm two ounces of Engliſh ſaffron tied up in a cloth, that the liquor may run through it, and extract all its tincture; and in order to this, you ſhould frequently preſs the ſaffron with your fingers. When the operation is finiſhed, dulcify your goods with fine ſugar.

Ratafia. Is a liquor prepared from different kinds of fruits, and is of different colours according to the fruits made uſe of. Of red ratafia there are three kinds, the fine, the dry or ſharp, and the common. The fruits moſt proper for making red ratafia, are the black heart cherry, the common red cherry, the black cherry, the mery or honey cherry, the ſtrawberry, the raſberry, the red gooſeberry, and the mulberry. Theſe fruits ſhould be gathered when in their greateſt perfection, and the largeſt and moſt beautiful of them choſen for the purpoſe. The following is a receipt for making red ratafia, fine and ſoft. Take of the black heart cherries 24 pounds; black cherries, four pounds; raſberries and ſtrawberries, of each three pounds. Pick the fruits from their ſtalks, and bruiſe them; in which ſtate let them continue 12 hours: preſs out the juice; and to every pint of it add a quarter of a pound of ſugar. When the ſugar is diſſolved, run the whole through the filtrating bag, and add to it three quarts of clean proof ſpirits. Then take of cinnamon, four ounces; of mace, an ounce; and of cloves, two drams. Bruiſe theſe ſpices; put them into an alembic with a gallon of clean proof ſpirits and two quarts of water, and draw off a gallon with a briſk fire. Add as much of this ſpicy ſpirit to your ratafia as will render it agreeable to your palate; about one fourth is the uſual proportion.

Ratafia made according to the above receipt will be of a very rich flavour and elegant colour. It may be rendered more or leſs of a ſpicy flavour, by adding or diminiſhing the quantity of ſpirit diſtilled from the ſpices. Some, in making ratafia, ſuffer the expreſſed juices of their fruits to ferment ſeveral days: by this means the vinoſity of the ratafia is increaſed; but, at the ſame time, the elegant flavour of the fruits is greatly diminiſhed. Therefore, if the ratafia is deſired ſtronger or more vinous, it may be done by adding more ſpirits to the expreſſed juice; by which means the flavour of the fruits may be preſerved, as well as the ratafia rendered ſtronger. It is alſo a method with ſome to tie the ſpices in a linen bag, and ſuſpend them in the ratafia. But if this method is taken, it will be neceſſary to augment the quantity of ſpirit firſt added to the expreſſed juice. There is no great difference in the two methods of adding the ſpices, except that by ſuſpending them in the ratafia the liquor is rendered leſs tranſparent.

Dry or Sharp Ratafia. Take cherries and gooſeberries, of each 30 pounds; mulberries, ſeven pounds; raſberries, ten pounds. Pick all theſe fruits clean from their ſtalks, &c. bruiſe them, and let them ſtand 12 hours; but do not ſuffer them to ferment. Preſs out the juice, and to every pint add three ounces of ſugar. When the ſugar is diſſolved, run it through the filtrating bag, and to every five pints of liquor, add four pints of clean proof ſpirit; together with the ſame proportion of ſpirit drawn from the ſpices in the foregoing compoſition.

Common Ratafia. Take of nutmegs, eight ounces; bitter almonds, ten pounds; Liſbon ſugar, eight pounds; ambergreaſe, ten grains: infuſe theſe ingredients three days in ten gallons of clean proof ſpirit, and filter through a flannel bag for uſe. The nutmegs and bitter almonds muſt be bruiſed, and the ambergreaſe rubbed with Liſbon ſugar in a marble mortar, before they are infuſed in the ſpirit.

Gold Cordial. Take of the roots of angelica, four pounds; raiſins ſtoned, two pounds; coriander-ſeeds, half a pound; caraway-ſeeds and cinnamon, of each half a pound; cloves, two ounces: figs and liquorice-root, of each one pound; proof ſpirit eleven gallons; water, two gallons. The angelica, liquorice, and figs, muſt be ſliced before they are added. Digeſt two days; and draw off by a gentle heat till the faints begin to riſe; hanging in a piece of linen, faſtened to the mouth of the worm, an ounce of Engliſh ſaffron. Then diſſolve eight pounds of ſugar in three quarts of roſe-water, and add to it the diſtilled liquor.

Geneva. There was formerly ſold in the apothecaries ſhops a diſtilled ſpirituous water of juniper: but the vulgar being fond of it as a dram, the diſtillers ſupplanted the apothecaries, and ſold it under the name of geneva. The common kind, however, is not made from juniper-berries, but from oil of turpentine; and indeed it is ſurpriſing, that people ſhould accuſtom themſelves to drink ſuch liquors for pleaſure. The receipt for making this kind of ſpirit, ſold in the gin-ſhops at London, is as follows. Take of the ordinary malt ſpirits, ten gallons; oil of turpentine, two ounces; bay-ſalt, three handfuls: draw off by a gentle fire till the faints begin to riſe; and make up your goods to the ſtrength required with clear water.

The beſt kind is made by the following recipe. Take of juniper-berries, three pounds; proof ſpirit, ten gallons; water, four gallons: draw off by a gentle fire till the faints begin to riſe, and make up your goods to the ſtrength required with clean water.

There is a ſort of this liquor called Hollands Geneva, from its being imported from Holland, which is greatly eſteemed. The ingredients uſed by the Dutch, are the ſame with thoſe given in the laſt recipe; only, inſtead of malt-ſpirits, they uſe French brandy. But from what has been already obſerved concerning the nature of theſe kinds of ſpirits, it is eaſy to ſee, that by the help of a well rectified ſpirit, geneva may be made in this country at leaſt nearly equal to the Dutch, provided it is kept to a proper age; for all ſpirituous liquors contract a ſoftneſs and mellowneſs by age, impoſſible to be imitated any other way.

Brewing for Distillation. See Brewing.

Distillation *of Salt Water*, in order to obtain freſh. See *Salt* Water.

DISTILLER, a perſon who diſtills ſpirits for ſale. Such a perſon is liable to the ſurvey and duties; and is not allowed to have any ſtill or number of ſtills, which ſingly or together contain leſs than a hundred gallons under the penalty of 100l. and the waſh-ſtill ſhall contain at leaſt four hundred gallons, excluſive of the head, under the ſame penalty. 2 Geo. III. c. 5. and 14 Geo. III. c. 73.

DISTINCT *Notion*, or *Idea*, is, when we can enumerate marks and characters enough whereby to recollect a thing. Such, e. gr. is this; that a circle is a figure bounded with a curve line that returns into itſelf; all the points whereof are equally diſtant from one middle part.

DISTINCTION, a diverſity in things, or conceptions. Logicians define diſtinction, an aſſemblage of two, or more words, whereby diſparate things, or their conceptions, are denoted.

DISTORTION, in medicine, is when any part of the human body remarkably deviates from its natural ſhape or poſition. Diſtortions of different parts may ariſe either from a convulſion or palſy; though ſometimes a terrible diſtortion in the ſhape of the whole body hath ariſen merely from careleſſneſs and ill habits. Mr. Winſlow, in the Memoirs of the Academy of Sciences at Paris, gives a very remarkable account of a lady of quality, whom he had known to be perfectly ſtraight for ſeveral years; but who taking afterwards to a ſedentary courſe of life, got a cuſtom of dreſſing herſelf very careleſsly, and of leaning as ſhe ſat, either forwards, or to a ſide. It was not many months before ſhe found it painful and troubleſome to ſtand or ſit upright: and ſoon afterwards ſhe found an inequality in the lower part of the back-bone. Alarmed at this, ſhe conſulted the gentleman who gave the account. To prevent the increaſe of the malady, he ordered her to wear a particular ſort of jumps inſtead of ſtays, and had a pad of a proper ſize applied: but this was ſoon neglected; and the conſequence was, that in a little time the back-bone became more and more crooked, and at length bent itſelf ſidewiſe in two contrary directions, ſo as to repreſent the figure of the Roman S; and the lady, ſtill refuſing to take the proper meaſures, loſt a fourth part of her height: and continued for the remainder of her life, not only crooked from right to left, and from left to right, but ſo oddly folded together, that the firſt of the falſe ribs on one ſide, approached very near the creſt of the os ilium on that ſide, and the viſcera of the lower belly became ſtrangely puſhed out of their regular places to the oppoſite ſide: and the ſtomach itſelf was ſo ſtrongly compreſſed, that whatever ſhe ſwallowed ſeemed to her to fall into two ſeparate cavities.

DISTORTOR *Oris*, in anatomy, a muſcle of the mouth, called alſo zygomaticus. See Syſtem of Anatomy, Sect. IX.

DISTRAIN, in law. To diſtrain, is to attach, or ſeize on one's goods, for the ſatisfaction of a debt.

DISTRESS, in law, the ſeizing or diſtraining any thing for rent in arrear, or other duty unperformed.

The effect of this diſtreſs is to compel the party either to replevy the things diſtrained, and conteſt the taking, in an action of treſpaſs againſt the diſtrainer; or rather to oblige him to compound and pay the debt or duty for which he was ſo diſtrained.

There are likewiſe compulſory diſtreſſes in actions, to cauſe a perſon to appear in court; of which kind there is a diſtreſs perſonal of one's moveable goods, and the profits of his lands, for contempt in not appearing after ſummons: there is likewiſe diſtreſs real, of a perſon's immoveable goods. In theſe caſes none ſhall be diſtrained to anſwer for any thing touching their freeholds, but by the king's writ.

Diſtreſs may be either finite or infinite. Finite diſtreſs is that which is limited by law, in regard to the number of times it ſhall be made, in order to bring the party to a trial of the action. Infinite diſtreſs is that which is without any limitation, being made till the perſon appears: it is farther applied to jurors that do not appear; as, upon a certificate of aſſiſe, the proceſs is *venire facias, habeas corpora*, and diſtreſs infinite.

It is alſo divided into grand diſtreſs, and ordinary diſtreſs: of theſe the former extends to all the goods and chattels that the party has within the county. A perſon, of common right, may diſtrain for rents and all manner of ſervices; and where a rent is reſerved on a gift in tail, leaſe for life, or years, &c. though there be no clauſe of diſtreſs in the grant or leaſe, ſo as that he has the reverſion: but on a feoffment made in fee, a diſtreſs may not be taken, unleſs it be expreſsly reſerved in the deed.

DISTRIBUTION, in a general ſenſe, the act of dividing a thing into ſeveral parts, in order to the diſpoſing each in its proper place.

Distribution, in law, the ſurplus of an eſtate, or *pour autre vie*, is diſtributable by adminiſtrators.

Distribution, in logic, is a kind of diviſion which diſtinguiſhes an univerſal whole into its ſeveral kinds or ſpecies. The rules of a good diſtribution are much the ſame as thoſe of diviſion.

Distribution, in painting, denotes the diſpoſition of the objects and lights in a picture. See Clair-Obscure.

Distribution, in printing, the taking a form aſunder, ſeparating the letters, and diſpoſing them in the caſes again, each in its proper cell.

Distribution, in rhetoric, is a kind of deſcription; or a figure whereby an orderly diviſion and enumeration is made of the principal qualities of a ſubject.

DISTRICT, the territory, or extent of juriſdiction of a judge. judge or officer, cannot act out of his own diſtrict.

District, in law, properly denotes the place wherein a man has the power of diſtraining; or, the circuit, or territory, wherein one may be compelled to appear. Where we ſay, *hors de ſon fee*; others ſay, *extra diſtrictum ſuum*.

DISTRINGAS, a writ directed to the ſheriff, or other officer commanding him to diſtrain one for a debt to the king; or for his appearance at a certain day.

Distringas *Juratores*, a writ directed to the ſheriff, whereby he is commanded to diſtrain upon a jury to appear, and to return iſſues on their lands, &c. for non-appearance. This writ iſſues for the ſheriff to have their bodies in court, &c. at the return of the writ.

DISVELOPED, in heraldry, is uſed much in the ſame ſenſe with diſplayed. Thus colours, ſaid in an army to be flying, are, in heraldry, ſaid to be diſveloped.

DITCH, in agriculture. In marſhes, and other wet land, where there are no hedges, the common fence and incloſure for land is a ditch. They allow theſe ditches ſix feet wide againſt highways that are broad, and againſt commons five feet. But the common ditches about incloſures, dug at the bottom of the bank, on which the quick is raiſed, are three feet wide at the top, one at the bottom, and two feet deep; by this means each ſide has a ſlope, which is of great advantage; for where they neglect this, and dig them perpendicular, they are always waſhing down: beſide, in a narrow bottomed ditch, if cattle get down into it, they cannot ſtand to turn themſelves to crop the quick; but where the ditch is four feet wide, it ſhould be two and a half deep; and where it is five wide, it ſhould be three deep; and ſo in proportion.

Ditch, in fortification, called alſo foſs and moat, a trench dug round the rampart, or wall of a fortified place, between the ſcarp and counterſcarp. See Syſtem of Fortification.

Ditch *Water*. See Water.

DITHYRAMBUS, Διθυραμβος, in the ancient poetry, a hymn in honour to Bacchus, full of tranſport and poetical rage. This poetry owes its birth to Greece, and to the tranſports of wine; and yet art is not quite exploded, but delicately applied to guide and reſtrain the dithyrambic impetuoſity, which is indulged only in pleaſing flights. Horace and Ariſtotle tell us, that the ancients gave the name of dithyrambus to thoſe verſes wherein none of the common rules or meaſures were obſerved. As we have now no remains of the dithyrambus of the ancients, we cannot ſay exactly what their meaſure was.

DITONE, Ditonum, in muſic, an interval comprehending two tones, a greater and a leſs. The word is formed of δις, *twice*, and τονος, *tone*.

DITTO, in books of accounts, written contractedly D°. ſignifies the ſame, viz. as the preceding article.

The word is corrupted from the Italian *detto*, *the ſaid*; as in our law phraſe "the ſaid premiſes," meaning the ſame as were aforementioned.

DIVAN, a council-chamber, or court, wherein juſtice is adminiſtered, in the eaſtern nations, particularly among the Turks. Divan is an Arabic word, ſignifying the ſame with *ſopha* in the Turkiſh dialect. There are two ſorts of divans, that of the grand ſignior, called the council of ſtate, which conſiſts of ſeven of the principal officers of the empire; and that of the grand vizir, compoſed of ſix other vizirs, or counſellors of ſtate, the chancellor and ſecretaries of ſtate, for the diſtribution of juſtice. The word is alſo uſed for a hall, in the private houſes of the orientals. The cuſtom of China does not allow the receiving of viſits in the inner parts of the houſe, but only at the entry, in a divan contrived on purpoſe for ceremonies. Travellers relate wonders of the ſilence and expedition of the divans of the Eaſt.

Divan-*Beghi*, the appellation of one of the miniſters of ſtate in Perſia. The divan-beghi is the ſuperintendant of juſtice; his place is the laſt of the ſix miniſters of the ſecond rank, who are all under the athemadaulet, or firſt miniſter. In the tribunal of the divan-beghi appeals lie from ſentences paſſed by the governors. He has a fixed ſtipend, or appointment, of 50,000 crowns, that he may render juſtice gratis. All the ſerjeants, uſhers, &c. of the court, are in the ſervice of the divan-beghi. He takes cognizance of the criminal cauſes of the chams, governors, and other great lords of Perſia, when accuſed of any fault, and receives appeals from the daruga. There are divan-beghis not only at court, and in the capital, but alſo in the provinces, and other cities of the empire. This officer is not confined by any other law or rule, in the adminiſtration of juſtice, but the Alcoran, which alſo he interprets at pleaſure. He takes no cognizance of civil cauſes.

DIVER, in ornithology, the Engliſh name of the colymbus, a genus of water birds, belonging to order 9 of the 2d diviſion.

DIVERGENT, or Diverging *Lines*, in geometry, are ſuch whoſe diſtance is continually increaſing. Lines which converge one way, diverge the oppoſite way.

Divergent, or *Diverging*, in optics, is particularly applied to rays, which, iſſuing from a radiant point, or having in their paſſage undergone a refraction, or reflection, do continually recede farther from each other. In which ſenſe the word is oppoſed to convergent, which implies the rays to approach each other; or to tend to a centre, where, being arrived, they interſect; and, if continued farther, become diverging. Concave glaſſes render the rays diverging; and convex ones, converging. Concave mirrors make the rays converge; and convex ones, diverge. See Syſtem of Optics.

DIVERSIFYING, in rhetoric, is of infinite ſervice to the orator; it is an accompliſhment eſſential to his character, and may fitly be called the ſubject of all his tropes and figures. Voſſius lays down ſix ways of diverſifying a ſubject. 1. By enlarging on what was briefly mentioned before. 2. By a conciſe enumeration of what had been inſiſted on at length. 3. By adding ſomething new to what is repeated. 4. By repeating only the principal heads of what had been ſaid. 5. By tranſpoſing the words and periods. 6. By imitating them. Voſſ. Rhet. lib. v. p. 281, ſeq.

DIVERSION, in medicine, the turning of the courſe or flux of humours from one part to another, by proper applications.

Diversion, in war, the act of attacking an enemy in one place, where he is weak, and unprovided, with deſign to make him call his forces from another place, where he was going to make an irruption, or is to be attacked with greater force. The Romans had no way to drive Hannibal out of Italy, but to make a diverſion, by attacking Carthage.

DIVERSITY. This differs from diſtinction in this, that the latter is the work of the mind; but the former is in things themſelves, antecedent to the operation of the mind. For things that are ſeveral, are different; even though I do not conceive them. The diverſity, or difference of things, therefore, ariſes from their eſſential attributes.

DIVERSITY, in painting, conſiſts in giving every part or figure in a picture its proper air and attitude. The ſkilful painter has the penetration to diſcern the characters of nature, which vary in all men; whence the countenances and geſtures of the perſons he paints continually vary.

DIVESTING, properly ſignifies undreſſing, or ſtripping off one's garment, in contradiſtinction from inveſting. In law, it is uſed for the act of ſurrendering, or relinquiſhing one's effects. By a contract of donation, or ſale, the donor, or ſeller, is ſaid to be diſſeiſed and diveſted of their property in ſuch a commodity, and the donee, or purchaſer, becomes inveſted therewith. A demiſe is a general diveſtiture, which the fathers and mothers make of all their effects, in favour of their children.

DIVIDEND, in arithmetic, the number given to be divided: or that whereof the diviſion is made. The dividend muſt always be greater than the diviſor. The dividend contains the diviſor as many times as the quotient contains units. See Syſtem of Arithmetic, Article V.

Dividend *of a Bankrupt's Eſtate*, is that part which is diſtributed to every creditor in proportion to his debt.

Dividend *of Stocks*, is a ſhare or proportion of the intereſt of ſtocks erected on public funds, as the South Sea, India, Bank, &c. divided among and payable half-yearly to the ſtock-holders; and the orders they have for receiving theſe dividends, are called dividend-warrants. Stealing any dividend-warrants of the Bank, South Sea Company, Eaſt India Company, or of any other corporation, is made felony, with or without benefit of clergy, in the ſame manner as if the offender had ſtolen, or taken by robbery, goods to the value of the money due on ſuch dividend warrants. Stat. 2 Geo. II. c. 25.

DIVIDIVI, the name of a drug brought from the Caraccas into Spain in 1769; and which, by experiments that have been made upon it at Madrid, is found to be preferable to galls in dying black.

DIVIDUAL, in arithmetic, is uſed for that part of the dividend diſtinguiſhed by a point, in working by the rule of diviſion.

DIVINATION, the knowledge of things obſcure, or future, which cannot be attained by any natural means. It was a received opinion among the heathens, that the gods were wont to converſe familiarly with ſome men, whom they endowed with extraordinary powers, and admitted to the knowledge of their councils and deſigns. Plato, Ariſtotle, Plutarch, Cicero, and others, divide divination into two ſorts or ſpecies, viz. natural and artificial.

Divination of all kinds was neceſſarily made an occult ſcience, which naturally remained in the hands of the prieſts and prieſteſſes, the magi, the ſoothſayers, the augurs, the viſionaries, the prieſts of the oracles, the falſe prophets, and other like profeſſors, till the time of the coming of Jeſus Chriſt. The light of the goſpel, it is true, has diſſipated much of this darkneſs; but it is more difficult, than is commonly conceived, to eradicate from the human mind a deep-rooted ſuperſtition, even though the truth be ſet in the ſtrongeſt light, eſpecially when the error has been believed almoſt from the origin of the world; ſo we ſtill find exiſting among us the remains of this pagan ſuperſtition, in the following chimeras, which enthuſiaſtic and deſigning men have formed into arts and ſciences; though it muſt be owned, to the honour of the 18th century, that the pure doctrines of Chriſtianity, and the ſpirit of philoſophy, which become every day more diffuſed, equally concur in baniſhing theſe viſionaries opinions. The vogue for theſe pretended ſciences and arts, moreover, is paſt, and they can no longer be named without exciting ridicule in all ſenſible people. By relating them here, therefore, and drawing them from their obſcurity, we only mean to ſhow their futility, and to mark thoſe rocks againſt which the human mind, without the aſſiſtance of a pilot, might eaſily run.

For the attaining of theſe ſupernatural qualifications, there are ſtill exiſting in the world the remains of,

1. Aſtrology; a conjectural ſcience which teaches to judge of the effects and influences of the ſtars; and to predict future events by the ſituation of the planets and their different aſpects. It is divided into natural aſtrology, or meteorology; which is confined to the foretelling of natural effects, as the winds, rain, hail, and ſnow, froſts and tempeſts. In this conſiſts one branch of the art of almanack-makers; and by merely confronting theſe predictions in the calendar, which the weather each day produces, every man of ſenſe will ſee what regard is to be paid to this part of aſtrology. The other part, which is called judicial aſtrology, is ſtill far more illuſive and raſh than the former: and having been at firſt the wonderful art of viſionaries, it afterwards became that of impoſtors; a very common fate with all thoſe chimerical ſciences, of which we ſhall here ſpeak. This art pretends to teach the method of predicting all ſorts of events that ſhall happen upon the earth, as well ſuch as relate to the public, as to private perſons; and that by the ſame inſpection of the ſtars and planets, and their different conſtellations. The cabala ſignifies, in like manner, the knowledge of things that are above the moon, as the celeſtial bodies and their influences; and in this ſenſe it is the ſame with judicial aſtrology, or makes a part of it.

2. Horoſcopy, which may alſo be conſidered as a part of aſtrology, is the art by which they draw a figure, or celeſtial ſcheme, containing the 12 hours, wherein they mark the diſpoſition of the heavens at a certain moment; for example, that at which a man is born, in order to foretel his fortune, or the incidents of his life. In a word, it is the diſpoſition of the ſtars and planets at the moment of any perſon's birth. But as there cannot be any probable or poſſible relation between the conſtellations and the human race, all the principles they lay down, and the prophecies they draw from them, are chimerical, falſe, abſurd, and a criminal impoſition on mankind.

3. Hydromancy is the ſuppoſed art of divining by water. The Perſians, according to Varro, invented it; Pythagoras and Numa Pompilius made uſe of it; and we ſtill admire the like wonderful prognoſticators.

4. Geomancy was a divination made by obſerving of cracks or clefts in the earth. It was alſo performed by points made on paper, or any other ſubſtance, at a venture; and they judged of future events from the figures that reſulted from thence. This was certainly very ridiculous; but it is nothing leſs ſo to pretend to predict future events by the inſpection of the grounds of a diſh of tea or coffee, or by cards, and many other like matters. Thus have deſigning men made uſe of the four elements to deceive their credulous brethren.

5. Chiromancy is the art which teaches to know, by inſpecting the hand, not only the inclinations of a man, but his future deſtiny alſo. The fools or impoſtors who practiſe this art pretend, that the different parts or the lines of the hand have a relation to the internal parts of the body, as ſome to the heart, others to the liver, ſpleen, &c. On this falſe ſuppoſition, and on many others equally extravagant, the principles of chiromancy are founded: and on which, however, ſeveral authors, as Robert Flud an Engliſhman, Artemidorus, M. de la Chambre, John of Indagina, and many others, have written large treatiſes.

6. Phyſiognomy, or phyſiognomancy, is a ſcience that pretends to teach the nature, the temperament, the underſtanding, and the inclinations of men, by the inſpection of their countenances, and is therefore equally frivolous with their chiromancy; though Ariſtotle, and a number of learned men after him, have wrote expreſs treatiſes concerning it.

DIVINE, ſomething that comes from or relates to God. The word is alſo uſed figuratively, for any thing that is excellent, extraordinary, and that ſeems to go beyond the power of nature, and the capacity of mankind. In which ſenſe, the compaſs, teleſcope, clocks, &c. are ſaid to be divine inventions: Plato is called the *divine author*, the *divine Plato*; and the ſame appellation is given to Seneca: Hippocrates is called the *divine old man, divinus ſenex*, &c.

DIVING, the art or act of deſcending under water, to conſiderable depths, and abiding there a competent time. The uſes of diving are very conſiderable, particularly in the fiſhing for pearls, corals, ſponges, &c. See Pearl *Fiſhing*.

There have been divers methods propoſed, and engines contrived, to render the buſineſs of diving more ſafe and eaſy. The great point in all theſe is to furniſh the diver with freſh air, with-but which he muſt either make but a ſhort ſtay, or periſh. Thoſe who dive for ſpongies in the Mediterranean, help themſelves by carrying down ſponges dipt in oil in their mouths. But conſidering the ſmall quantity of air that can be contained in the pores of a ſponge, and how much that little will be contracted by the preſſure of the incumbent water, ſuch a ſupply cannot long ſubſiſt the diver. For it is found by experiment, that a gallon of air included in a bladder, and by a pipe reciprocally inſpired and expired by the lungs, becomes unfit for reſpiration in little more than one minute of time. For though its elaſticity be but little altered paſſing the lungs, yet it looſes its vivifying ſpirit, and is rendered effete.

In effect, a naked diver, Dr. Halley aſſures us, without a ſponge, cannot remain above two minutes encloſed in water; nor much longer with one, without ſuffocating; nor without long practice, near ſo long; ordinarily perſons beginning to be ſuffocated in about half a minute. Beſides, if the depth be conſiderable, the preſſure of the water in the veſſels makes the eyes bloodſhotten, and frequently occaſions a ſpitting of blood.

Hence, where there has been occaſion to continue long at the bottom, ſome have contrived double flexible pipes, to circulate air down into a cavity encloſing the diver, as with armour, both to furniſh air, bear off the preſſure of the water, and permit his breaſt to dilate upon inſpiration; the freſh air being forced down one of the pipes with bellows, and returning by the other of them, not unlike to an artery and vein.

But this method is impracticable when the depth ſurpaſſes three fathoms; the water embracing the bare limbs ſo cloſely, as to obſtruct a circulation of the blood in them; and withal preſſing ſo ſtrongly on all the junctures where the armour is made tight with leather, that if there be the leaſt defect in any of them, the water ruſhes in, and inſtantly fills the whole engine, to the great danger of the divers life.

It is certain, however, that people, by being accuſtomed to the water from their infancy, will at length be enabled, not only to ſtay much longer under water than the time above-mentioned, but put on a kind of amphibious nature, ſo that they ſeem to have the uſe of all their faculties as well when their bodies are immerſed in water, as when they are on dry land. Moſt ſavage nations are remarkable for this. According to the accounts of our late voyagers, the inhabitants of the South-ſea iſlands are ſuch expert divers, that when a nail or any piece of iron was thrown overboard, they would inſtantly jump into the ſea after it, and never failed to recover it notwithſtanding the quick deſcent of the metal. Even among civilized nations, many perſons have been found capable of continuing an incredible length of time below water.

Diving *Bell*, is a machine contrived to remedy all theſe inconveniences. In this the diver is ſafely conveyed to any reaſonable depth, and may ſtay more or leſs time under the water, as the bell is greater or leſs. For a deſcription of this machine and other curious matters, See Syſtem of Hydrostatics.

Diving *Bladder*, a machine invented by Borelli, and by him preferred, though without any good reaſon, to the Diving Bell. It is a globular veſſel of braſs or copper, about two feet in diameter, which contains the divers head. It is fixed to a goat's ſkin habit exactly fitted to his perſon. Within the veſſel are pipes, by means of which a circulation of air is contrived; and the perſon carries an air-pump by his ſide, by which he can make himſelf heavier or lighter as fiſhes do, by contracting or dilating their air-bladder. By this means he thought all the objections to which other diving machines were liable, were entirely obviated and particularly that for want of air: the air which had been breathed, being, as he imagined, deprived of its noxious qualities, by circulating through the pipes. Theſe advantages, however, it is evident, are only imaginary. The diver's limbs, being defended from the preſſure of the water only by a goats ſkin, would infallibly be cruſhed if he deſcended to any conſiderable depth; and from the diſcoveries now made by Dr. Prieſtley and others, it is abundantly evident, that air, which is once rendered foul by breathing, cannot in any degree be reſtored by circulation through pipes. Concerning the uſe of copper machines in general: Mr. Spalding has favoured us with the following curious obſervation, namely, that when a perſon has breathed in them a few minutes, he feels in his mouth a diſagreeable braſſy taſte, which continues all the time he remains in the veſſel, ſo that, on this account, copper ſeems by no means an eligible material, this taſte moſt probably ariſes from the action of the alkaleſcent effluvia of the body upon the copper, for volatile alkali is a ſtrong diſſolvent of this metal: but how theſe effluvia volatiliſe the copper in ſuch a manner as to make the taſte of it ſenſible in the mouth is not eaſy to ſay.

DIVINITY, the quality, nature, and eſſence of God. It is falſly, that the atheiſts hold the nature of divinity to be a political invention of the ancient legiſlators, to ſecure and enforce the obſervation of their laws; on the contrary, it is certain, the legiſlators made uſe of that opinion, which they found already impreſſed on the minds of the people. The heathen divinities may be reduced to three claſſes: the firſt theological, repreſenting the divine nature under divers attributes: thus Jupiter denotes the abſolute power of God, Juno his juſtice, &c. The ſecond claſs of divinities are phyſical: thus Æolus is that power in nature, whereby vapours and exhalations are collected to form winds, &c. The laſt are moral divinities. Thus the furies are only the ſecret reproaches and ſtings of conſcience.

Divinity is alſo uſed in the ſame ſenſe with theology.

DIVISIBILITY, a paſſive power, or property in quantity, whereby it becomes ſeparable into parts; either actually or at leaſt mentally.

This the Peripatetics and Carteſians univerſally hold an affection, or property of all matter, or body: the Carteſians, as holding the eſſence of matter to conſiſt in extenſion: for every part, or corpuſcle of the body being extended, has parts including other parts, and conſequently is diviſible.

The Epicureans, again, hold diviſibility to agree to every phyſical continuum, as, without parts adjacent to parts, there can be no continuity; and wherever there are parts ſo adjacent, there muſt be diviſibility. But they deny, that this affection agrees to all bodies: for the primary corpuſcles, or atoms, they hold perfectly inſecable, and indiviſible.

The chief objections againſt this doctrine are, that an infinite cannot be contained by a finite; and that it follows from a *diviſibility in infinitum*, either that all bodies are equal, or that one infinite is greater than another. To which it is anſwered, that to an infinite may be attributed the properties of a finite and determined quantity; and who has ever proved, that there could not be an infinite number of parts infinitely ſmall in a finite quantity; or that all infinites are equal? The contrary is demonſtrated by mathematicians in innumerable inſtances. We are not here contending for the poſſibility of an actual diviſion *in infinitum*: we only aſſert, that however ſmall a body is, it may be ſtill farther divided; which we imagne may be called a diviſion *in infinitum*, becauſe what has no limits, is called *infinite*.

It is true, that there are no ſuch things as parts infinitely ſmall: yet the ſubtility of the particles of ſeveral bodies is ſuch, that they very much ſurpaſs our conception; and there are innumerable inſtances in nature of ſuch parts actually ſeparated from one another.

Mr. Boyle gives us ſeveral inſtances of this. He ſpeaks of a ſilken thread 300 yards long, that weighed but two grains and a half. He meaſured leaf gold, and found by weighing it, that fifty ſquare inches weighed but one grain: if the length of an inch be divided into 200 parts, the eye may diſtinguiſh them all; therefore there are in one ſquare inch 40000 viſible parts; and in one grain of it there are 2000000 of ſuch parts: which viſible parts no one will deny to be farther diviſible.

Again, a whole ounce of ſilver may be gilt with eight grains of gold, which may be afterwards drawn into a wire thirteen thouſand feet long.

In odoriferous bodies we can ſtill perceive a greater ſubtility of parts, and even ſuch as are actually ſeparated from one another; ſeveral bodies ſcarce loſe any ſenſible part of their weight in a long time, and yet continually fill a very large ſpace with odoriferous particles. The particles of light, if light conſiſts of real particles, furniſh another ſurpriſing inſtance of the minuteneſs of ſome parts of matter. A lighted candle placed on a plane will be viſible two miles, and conſequently fill a ſphere, whoſe diameter is four miles, with luminous particles, before it has loſt any ſenſible part of its weight. And as the force of any body is directly in proportion to its quantity of matter multiplied by its velocity; and ſince the velocity of the particles of light is demonſtrated to be at leaſt a million of times greater than the velocity of a canon ball, it is plain, that if a million of theſe particles were round, and as big as a ſmall grain of ſand, we durſt no more open our eyes to the light, than expoſe them to ſand ſhot point blank from a cannon.

By help of microſcopes, ſuch objects as would otherwiſe eſcape our ſight, appear very large: there are ſome ſmall animals ſcarce viſible with the beſt microſcopes; and yet theſe have all the parts neceſſary for life, as blood, and other liquors. How wonderful muſt the ſubtility of the parts be, which make up ſuch fluids! Whence is deducible the following theorem:

Any particle of matter, how ſmall ſoever, and any finite ſpace, how large ſoever, being given; it is poſſible for that ſmall ſand, or particle of matter, to be diffuſed through all that great ſpace, and to fill it in ſuch a manner, as that there ſhall be no pore in it, whoſe diameter ſhall exceed any given line; as is demonſtrated by Dr. Keil. Introduct. ad Ver. Phyſ.

DIVISION, in general, the act of ſeparating a whole into the parts it contains. If the whole be compoſed of parts really diſtinct, called integral parts, the diviſion made thereof is properly called partition; as when a houſe is divided into its apartments If the whole be compoſed of parts, called ſubjective; that is, if the whole be only one common term, the ſubjects compriſed in the extent whereof are the parts, the diviſion thereof is what we properly call diviſion: ſuch is the diviſion of a genus into its ſpecies, &c.

Division, in algebra, or ſpecies, is performed by reducing the dividend and diviſor into the form of a fraction; this fraction being the quotient. See Syſtem of Algebra, Sect. III.

Division, in arithmetic, is the laſt of the four fundamental rules, being that whereby we find how often a leſs quantity is contained in a greater; and the overplus. Diviſion, in reality, is only a compendious method of ſubtraction; its effect being to take a leſs number from another greater as often as poſſible; that is, as oft as it is contained therein. There are three numbers concerned in diviſion: 1. That given to be divided, called the dividend. 2. That whereby the dividend is to be divided, called the diviſor. 3. That which expreſſes how often the diviſor is contained in the dividend; or the number reſulting from the diviſion of the dividend by the diviſor, called the quotient. See Syſtem of ARITHMETIC, Article V.

DIVISION, in decimal fractions. See Syſtem of ARITHMETIC, Article XII.

DIVISION, in geometry, or geometrical diviſion. See Syſtem of GEOMETRY.

DIVISION *of a Word*, in grammar, is a diſcourſe explaining the latitude, or comprehenſion of a word: the latitude, when the word is univerſal; as when the genus is divided into ſpecies, and differenees; the comprehenſion, when the word is ambiguous, as *taurus*, *bull*; which ſometimes denotes a conſtellation, ſometimes a beaſt, and ſometimes a mountain.

DIVISION, in logic, is the ſeparating any thing into diverſe parts, or ideas.

DIVISION *of a Mode*, divides a quality into its degrees. Philoſophers, after the phyſicians, ſuppoſe eight degrees of every quality: hence when a quality is ſaid to be in the eighth degree, it marks, that it can be no farther intended, or heightened.

DIVISION, in muſic, imports the dividing of the interval of an octave into a number of leſſer intervals. The 4th and 5th, each of them, divide or meaſure the octave perfectly, though differently. When the 5th is below, and ſerves as a baſs to the 4th, the diviſion is called harmonical; when the 4th is below, the diviſion is called authentic.

DIVISION, in vulgar fractions. See Syſtem of ARITHMETIC, Article XI.

DIVISIONS *of an Army*, in the military art, the ſeveral brigades and ſquadrons into which it is cantoned.

DIVISIONS *of a Battalion*, the ſeveral platoons into which it is divided in marching or firing, each of which is commanded by an officer. See BATTALION.

DIVISION, in the ſea language, the third part of a naval army, or fleet; or one of the ſquadrons thereof, diſtinguiſhed by a particular flag or pendant, under the command of ſome flag officer. The white flag denotes the firſt ſquadron of France, the white and blue the ſecond, and the third is characterized by the blue. In England, the firſt admiral, or the admiral of the fleet, diſplays the union flag at the main-top-maſt-head; next follows the white flag with St. George's croſs; and afterwards the blue. The private ſhips carry pendants of the ſame colour with their reſpective ſquadrons at the maſts of their particular diviſions; ſo that the laſt ſhip in the diviſion of the blue ſquadron carries a blue pendant at her mizen-top-maſt-head. Naval battles are uſually ranged in three lines, according to their three diviſions.

DIVORCE, from *diverto*, *I turn away*, a breach or diſſolution of the bond of marriage. In our law, divorce is of two kinds; the one total, *a vinculo matrimonii*; which alone is properly *divorce*; the other partial, *a menſa & thoro*; a ſeparation from bed and board. The woman divorced, *a vinculo matrimonii*, receives all again that ſhe brought with her: the other has a ſuitable, ſeparate maintenance allowed her out of her huſband's effects. The firſt only happens through ſome eſſential impediment, as conſanguinity or affinity within the degrees forbidden, precontract, impotency, adultery, &c. of which impediments the canon law allows fourteen, comprehended in theſe verſes:

Error, conditio, votum, cognatio, crimen,
Cultus, diſparitas, vis, ordo, ligamen, honeſtas,
Si ſis affinis, ſi forte coire nequibis,
Si parochi & duplicis deſit præſentia teſtis,
Raptave ſit mulier, nec parti reddita tutæ.

In this kind of divorce, the marriage is declared null, as having been abſolutely unlawful, *ab initio*, and the parties are ſeparated *pro ſalute animarum*, and allowed to marry again; the iſſue of ſuch marriage as is thus entirely diſſolved, are baſtards. *Divorce a menſa & thoro*, diſſolveth not the marriage, becauſe it was juſt and lawful *ab initio*; but for ſome ſupervenient cauſe, it becomes improper or impoſſible for the parties to live together; as in the caſe of intolerable ill temper, or adultery, in either of the parties. However, *divorces a vinculo matrimonii*, for adultery, have of late years been frequently granted in England, by act of parliament.

Divorce is a ſpiritual judgment, and therefore is paſſed in the ſpiritual court. Under the old law, the woman divorced was to have of her huſband a writing, as St. Jerom and Joſephus teſtify, to this effect: *I promiſe, that hereafter I will lay no claim to thee*, which was called a *bill of divorce*.

Among the Jews, beſides incontinence and adultery, uglineſs, old age, or ill humour in a wife, were ſufficient reaſons for giving her a bill of divorce. Nay, even the man's own pleaſure, or his repenting of his match, were admitted as good reaſons. Selden de Uxore Heb. lib. iii. cap. 17.

It is generally held that Jeſus Chriſt allowed of divorce in the caſe of adultery. But ſome take this for a miſtake; and maintain, that divorce is no where permitted in the New Teſtament for adultery; but only a ſeparation. See Matt. xix. 9. Mark x. 11. Paul 1 Cor. vii. 27. See alſo the council of Florence, at the end, after the queſtions propoſed to the Greeks. Tertull. de Monogam. cap. 9. & 10. Auguſtin. de Bono Conjugio, & de Adult. Conjug.

In England divorce can only be had by conſent of parliament. Milton has an expreſs treatiſe of the doctrine and diſcipline of divorce, were he maintains, that divorce ought to be permitted for a mere incompatibility of humours.

DIURESIS, Διερησις, that ſeparation which is made of the urine by the kidneys. The word is formed from *δια*, *through*, and *ȣρεω*, *I make water*.

DIURETICS, in medicine, are ſuch remedies as provoke or promote the diſcharge of urine. Such is water drank plentifully, white wine drank in a morning; alkali ſalts of all kinds; ſea-ſalt, ſal gemmæ, nitre, borax, alum, tartar, ſal ammoniac, whey, ſour milk, lemon juice, &c. Aqueous liquors are generally diuretic, eſpecially if mixed with ſalt, and drank cold. Fermented liquors are the leaſt diuretic of all; and the leſs ſo, as they are the fatter. Sharp, thin, ſour wines, rheniſh, &c. as alſo acid ſpirits of vinegar, ſalt, ſulphur, alum, vitriol, &c. aſparagus, bitter almonds, ſmallage, eryngium, eupatorium, ſaſſafras, &c. are all diuretics.

DIURNAL, from *dies*, *day*, in aſtronomy, ſomething relating to the day; in oppoſition to nocturnal, which regards the night.

DIURNAL *Motion of a Planet*, is ſo many degrees and minutes, &c. as any planet moves in twenty-four hours. See Syſtem of ASTRONOMY, Sec. II.

The **DIURNAL** *Motion of the Earth*, is its rotation round its axis, the ſpace whereof conſtitutes the natural day. The reality of the diurnal motion of the earth is now paſt all diſpute. See Syſtem of ASTRONOMY, Sect. II.

DIURNAL is alſo uſed in ſpeaking of what belongs to the nycthemeron, or natural day of twenty-four hours. In which ſenſe it ſtands oppoſed to annual, menſtrual, &c.

DIVUS, **DIVA**, in antiquity, appellations given to men and women who had been deified, or placed in the number of the gods. Hence it is, that on medals ſtruck for the conſecration of an emperor or empreſs, they gave them the title of *Divus*, or *Diva*. For example: DIVUS JULIUS. DIVO ANTONINO PIO. DIVO PIO. DIVO CLAUDIO. DIVA FAUSTINA AUG. &c.

DIZZINESS, in medicine. See VERTIGO.

DOB-CHICK, or **DIDAPPER**, in ornithology, the common Engliſh name of a ſmall water fowl, the leaſt of all the diver kind, and known among authors by the name of colymbus minor; and called by Linnæus colymbus auritus. It ſeldom exceeds ſix ounces in weight, and has a ſhort beak, not more than a finger's breadth long, large at the baſe, but taperiog to a point at the end; its eyes are large, and it is covered with a very thick downy plumage: it is of a very deep blackiſh hrown on the back, and very white on the belly; its wings are very ſmall, and it has no tail.

DOCK, in botany, *Rumex*. See RUMEX.

DOCK, from δοχιον, *receptaculum*, of δεχομαι, *I receive*, in maritime affairs, a pit, pond, or creek, by the ſide of a harbour, made convenient to work in, in order to build or repair ſhips. This is of two ſorts: a dry dock, where the water is kept out by great flood-gates, till the ſhip is built, or repaired; but afterwards can be eaſily let into it again to float, and launch her. A wet dock is any place where a ſhip may be haled in, and ſo dock herſelf, or ſink herſelf a place to lie in; and where ſhe can be cleaned only during the receſs of the tide.

DOCK *Yards*, are magazines of all ſorts of naval ſtore, and timber for ſhip building; the royal dock yards in England, are thoſe at Chatham, Portſmouth, Plymouth, Woolwich, Deptford, and Sheerneſs. In time of peace, ſhips of war are laid up in theſe docks, thoſe of the firſt rates moſtly at Chatham, where, and at other yards, they receive, from time to time, ſuch repairs as are neceſſary. Theſe yards are generally ſupplied from the northern crowns, with hemp, pitch, tar, roſin, canvaſs, oak-plank, and ſeveral other ſpecies. But as for maſts, particularly thoſe of the largeſt ſize, they have been uſually brought from New England. The principal dock yards are governed by a commiſſioner, reſident at the port, who ſuperintends all the muſters of the officers, artificers, and labourers, employed in the dock yard and ordinary. He alſo controuls their payments; examines the accounts; contracts and draws bills on the navy-office to ſupply the deficiency of ſtores, and regulates whatever belongs to the yard, maintaining due order in the reſpective offices.

DOCKET, or **DOGGET**, in law, is a brief in writing, on a ſmall piece of paper, or parchment, containing the purport and effect of a larger writing. The rolls of judgment are docketted, when they are brought into the court of common-pleas, and entered on the docket of that term; ſo that by ſearching theſe dockets, any judgment may be found, if the attorney's name is known. Decrees in chancery are alſo docketted.

DOCTOR, a perſon who has paſſed all the degrees of a faculty, and is empowered to teach or practiſe the ſame. The title of doctor was firſt created towards the middle of the twelfth century; to ſucceed to that of maſter, which was become too common and familiar. It was ſoon transferred from the faculty of law to that of theology; the firſt inſtance whereof was given in the univerſity of Paris, where Peter Lombard, and Gilbert de la Potree, the two chief divines of thoſe days, were created doctors in theology, *ſacræ theologiæ doctores*. Others declare Bede to have been the firſt doctor at Cambridge, and John de Beverley at Oxford, which latter died in the year 721. But Spelman will not allow doctor to have been the name of any title or degree in England till the reign of king John, about the year 1207.

Doctor *of the Law*, was a title of honour or dignity among the Jews. The Jews it is certain, had doctors long before Jeſus Chriſt. The inveſtiture, if we may ſo ſay, of this order, was performed by putting a key, and a table book in their hands; which is what ſome authors imagine our Saviour had in view, Luke xi. 52, where, ſpeaking of the doctors of the law, he ſays, *Woe unto you, doctors of the law*; *for you have taken away the key of knowledge*; *you entered not in yourſelves, and them that were entering, you hindered*. The Greek text of St. Luke calls them *νομικοι*; and the Vulgate, *legiſperiti*; agreeably to which, our English tranſlators call them lawyers. But the French verſion of *docteurs de la loi*, ſeems the moſt adequate. In effect, the words *lawyer*, *legiſperitus*, is only found in St. Luke, and St. Paul, Titus iii. 13. And *νομικος*, in St. Matthew, xxii. 35, is rendered by the Vulgate, *legis doctor*; though the Engliſh verſion ſtill retains the word lawyer. Theſe Jewiſh doctors are the ſame whom they otherwiſe call Rabbins.

Doctor *of the Church*, a title given to certain of the fathers whoſe doctrines and opinions have been the moſt generally followed and authorized. We uſually reckon four doctors of the Greek church, and three of the Latin. The firſt are St. Athanaſius, St. Baſil, St. Gregory Nazianzen, and St. Chryſoſtom. The latter are St. Jerom, St. Auguſtine, and Gregory the Great.

Doctor is alſo an appellation adjoined to ſeveral ſpecific epithets, expreſſing wherein the merit of ſuch as the ſchools owned for their maſters, conſiſted.

Doctors *Commons*. See College *of Civilians*.

DOCTRINE, from *doceo*, *I teach*, denotes in general any thing that is taught, as a matter either of faith or practice; and the term has accordingly been applied to a variety of opinions, that have been adopted and inculcated in philoſophy, religion, &c. There are certain doctrines reſpecting the political conſtitution of Great Britain, the aſſerting and publiſhing of which are made illegal by ſtatute. Thus, if any perſon maliciouſly or adviſedly affirm, that both or either of the houſes of parliament have any legiſlative authority without the king, ſuch perſon ſhall incur all the penalties of a præmunire. 13 Car. II. cap. 1. Alſo if a perſon affirm and maintain, by writing or printing, that the king and parliament have no right to direct the ſucceſſion of the crown, he is guilty of high treaſon; and if he maintains the ſame doctrine by teaching, or adviſed ſpeaking, he incurs a præmunire. 13 Eliz. cap. 1. 6 Anne, cap. 7. There are alſo other doctrines of a religious nature, which it is unlawful publicly to maintain and preach.

DOCUMENT, in law, ſome written monument produced in proof of any fact aſſerted, eſpecially an ancient one.

DODDER, in botany. See Cuscuta.

DODECAGON, from *δοδεκα*, *twelve*, and *γωνια*, *angle*, a regular polygon, or figure, with twelve equal ſides and angles. Dials are ſometimes drawn on all the ſides of a dodecagon. In fortification, a place ſurrounded with twelve baſtions is called a dodecagon; ſuch is Palma Nova in Friuli, &c.

DODECAHEDRON, from *δωδεκα*, *twelve*, and *εδρα*, *ſeat*, in geometry, one of the regular bodies comprehended under twelve equal ſides, each whereof is a pentagon.

DODECANDRIA, (from *δωδεκα*, *twelve*, and *ανηρ*, *a man*); the name of the eleventh claſs in Linnæus's ſexual ſyſtem, conſiſting of plants with hermaphrodite flowers, that, according to the title, have twelve ſtamina or male organs. This claſs, however, is not limited with reſpect to the number of ſtamina. Many genera have ſixteen, eighteen, and even nineteen ſtamina; the eſſential character ſeems to be, that, in the claſs in queſtion, the ſtamina, however numerous, are inſerted into the receptacle; whereas, in the next claſs, Icoſandria, which is as little determined in point of number as the preſent, they are attached to the inſide of the calix or flower-cup.

The orders in this claſs, which are ſix, are founded upon the number of the ſtyles, or female organs. Aſarabacca, mangoſton, ſtorax, purple looſe-ſtrife, wild Syrian rue, and purſlane, have only one ſtyle; agrimony and heliocarpus have two; burning thorny plant, and baſtard rocket, three; *glinus*, five; *illicium*, eight; and houſe-leek, twelve. See Plate V.

DODO, Didus, in ornithology, a genus belonging to the 6th order and the firſt diviſion.

DODONÆUS, Dodonian, in antiquity, an epithet given to Jupiter, as adored, or worſhipped, in the temple of Dodona, in a foreſt of the ſame name. Dodona, whence the appellation ariſes, is an ancient city of Epirus, celebrated on divers accounts, as the foreſt of Dodona, the oracle of Dodona, and the fountain of Dodona.

DOE, the female of the buck.

DOG, *Canis*, in tetrapodology, an animal remarkable for its natural docility, fidelity, and affection for its maſter: which qualities mankind are careful to improve for their own advantage. Theſe uſeful creatures guard our houſes, gardens, and cattle, with ſpirit and vigilance. By their help we are enabled to take not only beaſts, but birds; and to purſue game both over land and through the waters. In ſome northern countries, they ſerve to draw ſleds, and are alſo employed to carry burdens. In ſeveral parts of Africa, China, and by the Weſt Indian negroes, dogs are eaten, and accounted excellent food. Nay, we have the teſtimony of Mr. Forſter, that dogs fleſh, in taſte, exactly reſembles mutton. They were alſo uſed as food by the Romans, and long before them by the Greeks, as we learn from ſeveral treatiſes of Hippocrates. In the preſent times, their ſkins, dreſſed with the hair on, are uſed in muffs, made into a kind of buſkins for perſons in the gout, and for other purpoſes. Prepared in another way, they are uſed for ladies gloves, and the linings of maſks, being thought to make the ſkin peculiarly white and ſmooth. The French import many of theſe ſkins from Scotland, under a ſmall duty. Here, when tanned, they ſerve for upper leathers for neat pumps.

With regard to the qualities of dogs, thoſe bred in the iſland of Britain are juſtly reckoned ſuperior to the dogs bred in any other country. The ſwiftneſs of the greyhound is amazing: as are alſo the ſteadineſs and perſeverance of other hounds and beagles; the boldneſs of terriers in unearthing foxes, &c.; the ſagacity of pointers and ſetting dogs, who are taught a language by ſigns as intelligible to ſportſmen as ſpeech; and the invincible ſpirit of a bull-dog, which can be quelled only by death. All the nations in Europe not only do juſtice to the ſuperior qualities of the Britiſh dogs, but adopt our terms and names, and thankfully receive the creatures as preſents. It is remarkable, however, that almoſt every kind of Britiſh dogs degenerate in foreign countries; nor is it poſſible to prevent this degeneracy by any art whatever.

Chuſing of Dogs. In order to chuſe a dog and bitch for good whelps, take care that the bitch come of a generous kind, be well proportioned, having large ribs and flanks; and likewiſe that the dog be of a good breed and young, for a young dog and an old bitch breed excellent whelps.

As to the training up a dog for ſporting, the maſter of him cannot begin when he is too young, the principal thing to be taught being obedience, and that being beſt taught while the creature is young. As ſoon as he can lap, he ſhould be taught to couch and lie cloſe at command, and not to dare to ſtir from that poſture till he is ordered: he will ſoon be brought to this, by beating when he diſobeys, and encouraging him when he does right. He ſhould always be taught before the times of his eating, and never have his food given him but when he has done ſomething to deſerve it. This will teach him always to do well, for the ſake of expected victuals. No perſon ſhould ever interfere in the teaching; for two maſters breed a confuſion, and the creature never will learn well from them.

The teacher muſt be careful always to uſe the ſame words in his leſſons; thoſe words are to be choſen which are the moſt plain in their ſounds, and the moſt diſtinct from one another; and when theſe are once fixed upon, they muſt never be altered; for the dog, being guided wholly by the ſound, and not at all by the ſenſe, any alteration of them, though the change be into words of the ſame ſenſe, quite confounds the creature. The word *down* is ſhort and expreſſive, and no other need be uſed when he is ordered to couch: but this being once given him is never to be varied afterwards. The next ſound he ſhould be taught after this, is the word of correction; for no leſſon can be given but faults will be committed, and no fault ſhould paſs without correction or blame; in this caſe, the word *ſirrah*, ſpoke angrily, will always be underſtood. This, at firſt, ſhould be uſed with a laſh or a blow, and after a time he will know it as a word of diſpleaſure, and it will do for ſmall faults without the blow. Certain words of cheriſhing and encouragement muſt alſo be taught him the ſame time, as *good boy*, or the like, uſing always with them actions and looks of chearfulneſs and pleaſure, as clapping him on the back, and the like. After theſe, he muſt be taught the meaning of ſome words of advice, to put him in mind of his buſineſs, when he is out upon the ſport, ſuch as take heed, or the like. Theſe will not only ſet him upon the watch, and make him diligent; but he will alſo be careful and cunning, and at the ſame time chearful and pleaſed in himſelf, as knowing that he is doing his maſter a pleaſure. The water ſpaniel ſhould be taught, to fetch and carry any thing he is commanded; this muſt be taught him by way of ſport, as a diverſion, by ſhaking a glove at his head, and teaching him to ſnatch it, and afterwards to catch it when thrown from the hand, and bring it back again; this he is to be encouraged in with cheriſhing words, and all other means.

When he has been perfected in all theſe leſſons, he muſt be taught his buſineſs of hunting: he is to be firſt taught with tame fowl, which his maſter is to aſſiſt him in taking, and reward and encourage him when he has done. After this he is to be ſent in without aſſiſtance to take the fowl alone; and if he ſucceeds, he is to be encouraged and rewarded, and corrected if he fails. By this practice he will ſoon become maſter of his game; but great care is to be taken in teaching him, when he has caught it, to bring it back to the ſhore, without biting or hurting it.

Many of theſe dogs are ſo expert, that they will have their eye upon the game as ſoon as their maſter; and the moment the gun is gone off, they will, without bidding, go and fetch it; but this is being too forward; and if he is uſed afterwards with nets or lime-twigs, he will do great miſchief, by ruſhing on the birds as ſoon as they are taken, and tearing the nets, or ſpoiling the twigs. Obedience is the beſt quality in this ſort of dog; and it is better he ſhould wait for command, than know his buſineſs without it. The ſportſmen, who know the time of birds moulting, make a very good uſe of this ſort of dog; taking him with them without gun, net, or any other aſſiſtance. The common moulting time of water fowl is from June to Auguſt; in this time they are not able to fly well; and in ſome part of it, when their old wing feathers are off, and the new ones are ſcarce grown, the dog is then to be taken to the ſides of rivers and other waters, and ſet to hunt about the cloſe places, among which they hide themſelves at this time: the dog being ſet to hunt, will eaſily find them in theſe retreats, and will take them either by leaping ſuddenly upon them, or fairly purſuing ſuch of them as have not the uſe of their wings. There is alſo another great uſe of the dog in driving them without catching them. This is practiſed only in mooriſh and fenny countries, where they are very numerous. In theſe countries a proper place is to be ſought for, where the birds retire to, and theſe are planted with nets; then the dog is ſent into the waters and places of covert, where they are ſuppoſed to be, and this at the moulting time, when they cannot fly away from him. The alarm he puts them into on the firſt attack, ſoon brings many others together, and there is a large body of them formed which the dog drives before him like a flock of ſheep; and being directed by the ſportſmen, frightens directly into the places of their retreat, where the nets are placed before hand to receive them.

As pointers and ſpaniels, when good of their kinds, and well broken, are very valuable to a ſportſman, it is worth while to take ſome care to preſerve them in health. This very much depends on their diet and lodging: frequent cleaning their kennels, and giving them freſh ſtraw to lie on, is very neceſſary; or, in ſummer time, deal ſhavings, or ſand, inſtead of ſtraw, will check the breeding of fleas. If you rub your dog with chalk, and bruſh him once or twice a week, he will thrive much the better; the chalk will clear his ſkin from all greaſineſs, and he will be the leſs liable to be mangy. A dog is of a very hot nature: he ſhould therefore never be without clean water by him, that he may drink when he is thirſty. In regard to their food, carion is by no means proper for them: it muſt hurt their ſenſe of ſmelling, on which the excellence of theſe dogs greatly depends. Barley meal, the droſs of wheat flour, or both mixed together, with broth or ſkimmed milk, is very proper food. For change, a ſmall quantity of greaves from which the tallow is preſſed by the chandlers, mixed with their flour, or ſheep's feet well baked or boiled, are a very good diet; and when you indulge them with fleſh, it ſhould always be boiled. In the ſeaſon of hunting your dogs, it is proper to feed them in the evening before, and give them nothing in the morning you intend to take them out except a little milk. If you ſtop for your own refreſhment in the day, you ſhould alſo refreſh your dogs with a little bread and milk. It has been already obſerved that dogs are of a hot conſtitution; the greateſt relief to them in the ſummer, is twitch-graſs, or dog-graſs, which is the ſame thing. You ſhould therefore plant ſome of it in a place where you can turn them into every morning: they will feed freely on it to be cured of the ſickneſs they are ſubject to, and cured of any extraordinary heat of blood: but unleſs the graſs be of this ſort, it will have no effect.

Dogs are ſubject to the mange from being fed too high, and allowed no exerciſe or an opportunity of refreſhing themſelves with dog graſs; or by being ſtarved at home, which will cauſe them to eat the vileſt ſtuff abroad, ſuch as carrion, or even human excrement; or by want of water, and ſometimes by not being kept clean in their kennel, or by foundering and melting in their greaſe. Either of theſe will heat the blood to a great degree, which will have a tendency to make them mangy. The cure may be effected by giving ſtone brimſtone powdered fine, either in milk or mixed up with butter, and rubbing them well every day for a week with an ointment made of ſome of the brimſtone and pork-lard, to which add a ſmall quantity of oil of turpentine. Or, boil four ounces of quickſilver in two quarts of water to half the quantity; bathe them every day with this water, and let them have ſome of it to lick till the cure is perfected. Or, a ſmall quantity of trooper's ointment rubbed on the parts on its firſt appearance will cure it. It will alſo free louſy puppies from their lice. Or, take two ounces of euphorbium; flour of ſulphur, Flanders oil of bays, and ſoft ſoap, each four ounces. Anoint and rub your dog with it every other day; give him warm milk, and no water. The cure will be performed in about a week.

If you ſuſpect your dog to be poiſoned with nux vomica (the poiſon uſually employed by the warreners, which cauſes convulſive fits and ſoon kills); the moſt effectual remedy, if immediately applied, is to give him a good deal of common ſalt; to adminiſter which, you may open his mouth, and put a ſtick acroſs to prevent his ſhutting it, whilſt you cram his throat full of ſalt, at the ſame time holding his mouth upwards; and it will diſſolve ſo that a ſufficient quantity will be ſwallowed to purge and vomit him. When his ſtomach is ſufficiently cleared by a free paſſage obtained by ſtool, give him ſome warm broth frequently, to prevent his expiring from faintneſs; and he will recover.

A pointer ought not to be hunted oftener than two or three days in a week: and unleſs you take care of his feet, and give him good lodging as well as proper food, he will not be able to perform that through the ſeaſon. You ſhould therefore, after a hard day's hunting, waſh his feet with warm water and ſalt; and when dry, waſh them with warm broth, or beer and butter, which will heal their ſoreneſs, and prevent a ſettled ſtiffneſs from fixing. If your dog has received any little wounds by forcing through hedges, or gets any lameneſs from a blow or ſtrain; bathe the wound or grieved part with ſalt and cold vinegar (for warming it only evaporates the fine ſpirit); and when dry, if a wound, you may pour in it a little friar's balſam, which will perform the cure ſooner than any method hitherto experienced.

The ſymptoms of madneſs are many and eaſily diſcerned. When any dog ſeparates himſelf contrary to his former uſe, becomes melancholy or droops his head, forbears eating, and as he runs ſnatches at every thing; if he often looks upwards, and his ſtern at his ſetting on be a little erect, and the reſt hanging down; if his eyes be red, his breath ſtrong, his voice hoarſe, and he drivels and foams at the mouth; you may be aſſured he has this diſtemper.

Of the ſeven ſorts of madneſs, two are incurable; the hot burning madneſs, and the running madneſs. The animals labouring under theſe are peculiarly dangerous: for all things they bite and draw blood from, will have the ſame diſtemper; and they generally ſeize on all they meet with, but chiefly on dogs: their pain is ſo great, it ſoon kills them.

When a dog happens to be bit by a mad one, there is nothing better than their licking the place with their own tongues, if they can reach it; if not, then let it be waſhed with butter and vinegar made luke warm, and let it afterwards be anointed with Venice turpentine; it is alſo good to piſs often on the wound; but, above all, take the juice of the ſtalks of ſtrong tobacco boiled in water, and bathe the place therewith; alſo waſh him in ſea water, or water artificially made ſalt: give him likewiſe a little mithridate inwardly in two or three ſpoonfuls of ſack, and ſo keep him apart; and if you find him after ſome time ſtill to droop, the beſt way is to hang him.

Dog, in aſtronomy, a name common to two conſtellations called the *Great* and *Little Dog*; but among the aſtronomers, more uſually, *Canis major*, and *minor*. See Canis *major & minor*.

Dog *Draw*, in the foreſt law, a manifeſt deprehenſion of an offender againſt veniſon in a foreſt; when he is found drawing after a deer by the ſcent of a hound led in his hand. There are four offences in the foreſt, viz. ſtable ſtand, dog-draw, back-bear or back-berond, and bloody hand.

Dog's *Bane*, in botany, apocynum. See Apocynum.

Dog-*Days*, Canicular, properly denote a certain number of days preceding and enſuing the heliacal riſing of the Canicula, or the dog ſtar, in the morning. Almanack makers uſually mark the beginning of the dog days from about the end of July, and end them about their firſt week in September.

Dog *Fly*, cynomyia, in entomology, the name of a ſpecies of fly common in woods and among buſhes, and particularly troubleſome to dogs. It uſually ſeizes upon the ears, and it is in vain to beat it off; for it returns in a moment, and cannot be prevented but by being killed. It ſtings very ſeverely, and always raiſes a bliſter in the part. It ſomewhat reſembles the flat black fly, ſo troubleſome to cattle. It has no trunk, but has two teeth, much reſembling thoſe of the waſp. Its wings are always placed ſo cloſe upon its body, that they are not ſeen. There are two kinds of it, one larger, and found in woods, and the other common in hedges.

Dog *Wood-tree*. See Piscidid.

DOGE, the chief magiſtrate in the republics of Venice and Genoa. The word properly ſignifies *duke*, being formed from the Latin *dux*; as *dogate* and *dogado*, from *ducatus*, *duchy*.

The dogate, or office and dignity of doge is elective: at Venice, the doge is elected for life; at Genoa, only for two years; he is addreſſed under the title of Serenity, which among the Venetians is ſuperior to that of highneſs.

The doge is the chief of the council, and the mouth of the republic: yet the Venetians do not go into mourning at his death, as not being their ſovereign, but only their firſt miniſter. In effect, the doge of Venice is no more than the phantom or ſhadow of the majeſty of a prince, all the authority being reſerved to the republic. He only lends his name to the ſenate; the power is diffuſed throughout the whole body, though the anſwers be all made in the name of the doge. If he gives any anſwers on his own account, they muſt be very cautiouſly expreſſed, and in general terms, otherwiſe he is ſure to meet with a reprimand. So that it is abſolutely neceſſary he be of an eaſy and pliable diſpoſition.

Anciently, the doges were ſovereigns; but things are much altered; and at preſent, all the prerogatives reſerved to the quality of doge, are thoſe which follow: he gives audience to ambaſſadors; but does not give them any anſwer from himſelf, in matters of any importance; only he is allowed to anſwer according to his own pleaſure to the compliments they make to the ſignory; ſuch anſwers being of no conſequence. The doge, as being firſt magiſtrate, is head of all the councils; and the credentials which the ſenate furniſhes its miniſters in foreign courts, are written in his name; and yet he does not ſign them; but a ſecretary of ſtate ſigns them, and ſeals them with the arms of the republic. The ambaſſadors direct their diſpatches to the doge; and yet he may not open them, but in preſence of the counſellors. The money is ſtruck in the doge's name, but not with his ſtamp or arms. All the magiſtrates riſe, and ſalute the doge, when he comes into council; and the doge riſes to none but foreign ambaſſadors.

The doge nominates to all the benefices in the church of St. Mark; he is protector of the monaſtery delle Virgine; and beſtows certain petty offices of uſhers of the houſhold, called *commanders of the palace*. His family is not under the juriſdiction of the maſter of the ceremonies; and his children may have ſtaff-officers, and gondoliers in livery.

His grandeur, at the ſame time, is tempered with a variety of circumſtances which render it burthenſome. He may not go out of Venice, without leave of the council; and if he does go out, he is liable to receive affronts, without being intitled to demand ſatisfaction; and, if any diſorder ſhould happen where he was, it belongs not to him, but to the podeſta, as being inveſted with the public authority, to compoſe it.

The children and brothers of the doge are excluded from all the chief offices of ſtate. They may not receive any benefice from the court of Rome; but are allowed to accept of the cardinalate, as being no benefice, nor including any juriſdiction. The doge may not diveſt himſelf of his dignity, for his eaſe; and after his death, his conduct is examined by three inquiſitors, and five correctors, who ſift it with great ſeverity.

DOGGS, machines of iron for burning wood on; alſo hooks fixed in large timbers, for drawing them with horſes.

DOGGER, a ſmall ſhip, built after the Dutch faſhion, with a narrow ſtern, and two maſts; viz. a main maſt, and a mizen maſt, principally uſed in fiſhing on the Doggers bank. See Plate II. *Fig.* 4. NAVAL ARCHITECTURE.

DOGGERS, in the Engliſh alum works, a name given by the workmen to a ſort of ſtone found in the ſame mines with the true alum rock, and containing ſome alum, though not nearly ſo much as the right kind. The county of York, which abounds greatly with the true alum rock, affords alſo a very conſiderable quantity of theſe doggers; and in ſome places they approach ſo nearly to the nature of the true rock, that they are wrought to advantage.

DOGMA, Δογμα, a maxim, tenet, ſettled propoſition, or principle; particularly in matters of religion, or philoſophy.

DOGMATICAL, ſomething relating to a doctrine, or opinion. Dogmatical philoſopher is one who aſſerts every thing poſitively; in oppoſition to a ſceptic, who doubts of every thing.

DOGMATICI, DOGMATISTS, a ſect of ancient phyſicians of which Hippocrates was the firſt author, called alſo, *logici, logicians*, from their uſing the rules of logic and reaſon, in ſubjects of their profeſſion. They laid down definitions, and diviſions, reducing diſeaſes to certain genera, thoſe genera to ſpecies, and furniſhing remedies for them all; ſuppoſing principles, drawing conſequences, and applying thoſe principles and conſequences to the particular diſeaſes under conſideration. In which ſenſe the dogmatiſts ſtand contradiſtinguiſhed to empirics, and methodiſts. They brought phyſic into a form and arrangement, like thoſe of other ſpeculative ſciences; defining, dividing, laying down principles, and drawing concluſions; and hence they had alſo the appellation of *logici*; q. d. *reaſoners*. They alſo applied themſelves to ſeek the cauſes of diſeaſes, the nature of remedies, &c.

DOLICHOS, kidney bean; a genus of the decandria order, belonging to the diadelphia claſs of plants. There are 25 ſpecies, the moſt uſeful of which are the following:

1. The lablab with a winding ſtalk, a native of warm climates, where it is frequently cultivated for the table. Mr. Haſſelquiſt informs us, that it is cultivated in the Egyptian gardens, but is not a native of that country. The Egyptians make pleaſant arbours with it in their houſes and gardens, by ſupporting the ſtem and leading it where they think proper. They not only ſupport it with ſticks and wood, but tie it with cords: by which means the leaves form an excellent covering, and an agreeable ſhade.

2. The urens, or cow-itch, alſo a native of warm climates, is generally eradicated from all cultivated grounds; becauſe the hairs from the pods fly with the winds, and torment every animal they touch. If it was not for this miſchievous quality, the beauty of its flowers would entitle it to a place in the beſt gardens. It flowers in the cool months, from September to March, according to the ſituation.

This plant has lately acquired a conſiderable reputation as an anthelmintic. As ſuch it is mentioned by Dr. Macbride, in his "Introduction to the theory and practice of phyſic," and by ſome other authors. From the teſtimonies of Mr. Cochrane ſurgeon at Nevis, and Mr. Bancroft author of a "Natural hiſtory of Guiana," we are aſſured that it is uſed in theſe countries with the greateſt ſafety and efficacy. Mr. Bancroft, after mentioning the frequency of diſorders ariſing from worms, in that part of the world, and aſſigning ſome reaſons for them, proceeds as follows: "But from whatever cauſe theſe worms are produced, their number is ſo great, that the uſual remedies are very inſufficient for their deſtruction: for which reaſon the planters in general have recourſe to the cow-itch for that purpoſe. From whence its uſe was firſt ſuggeſted, I am uncertain; but its efficacy is indiſputable. The part uſed is the ſetaceous hairy ſubſtance growing on the outſide of the pod, which is ſcraped off, and mixed with common ſyrup or molaſſes, to the conſiſtence of a thin electuary; of which a tea-ſpoonful to a child of two or three years old, and double the quantity to an adult, is given in the morning faſting, and repeated the two ſucceeding mornings; after which a doſe of rhubarb is uſually ſubjoined. This is the empirical practice of the planters, who uſually once in three or four months exhibit the cow-itch in this manner to their ſlaves in general, but eſpecially to all their children without diſtinction; and in this manner I have ſeen it given to hundreds, from one year old and upwards, with the moſt happy ſucceſs. The patients, after the ſecond doſe, uſually diſcharged an incredible number of worms, even to the amount of more than 20 at a time; ſo that the ſtools conſiſted of little elſe than theſe animals. But though theſe were indiſputable proofs of its efficacy, I was far from being convinced of its ſafety. I obſerved that the ſubſtance given conſiſted of an aſſemblage of ſpiculæ exquiſitely fine, and ſo acutely pointed, that, when applied to the ſkin, they excited an intolerable itching, and even inflammation; from whence I apprehended dangerous conſequences from their contact with the coats of the ſtomach and inteſtines. Indeed, when mixed with an electuary in the manner in which they are given, their elaſticity is ſo impaired, that they do not produce the ſame ſenſible irritation: but yet I could conceive no other quality on which their efficacy depended; eſpecially after I had prepared both a tincture and decoction from the cow-itch, and given them to worm patients without any ſenſible advantage. Influenced by theſe ſuggeſtions, I particuliarly examined the ſtate and condition of all ſuch patients as I knew had taken the cow-itch; and yet can with the greateſt truth declare, that, though prejudiced to its advantage, I was never able, either by my own obſervation or a diligent inquiry, to diſcover a ſingle inſtance of any ill conſequence reſulting from its uſe: which has been ſo extenſive, that ſeveral thouſands muſt have taken it, and as no ill effects have been obſerved, I think not only its efficacy, but ſafety, are ſufficiently evinced, to entitle it to general uſe, eſpecially when we reflect on the uncertainty, and even danger, which attends other vermifuges. It is to be obſerved, that this remedy is particularly deſigned againſt the long round worm. Whether it is equally deleterious to the aſcarides, or whether it has ever been uſed againſt them, is uncertain."

DOLLAR, a ſilver coin, nearly of the value of the Spaniſh piece of eight, or French crown. Dollars are coined in divers parts of Germany and Holland; and have their diminutions, as rix dollars, ſemi dollars, quarter dollars, &c. They are not all of the ſame fineneſs, nor weight. The Dutch dollars are the moſt frequent. In the Levant they are called *oſtaini*, from the impreſſion of a lion thereon.

DOLPHIN. See DELPHINUS.

DOLPHINS *of a Cannon*, in gunnery, are the two handles placed on the ſecond reinforce rings of braſs guns, reſembling the fiſh of that name. They ſerve for mounting and diſmounting the guns.

DOLPHIN *of the Maſt*, in ſea language, is a peculiar kind of wreath, formed of platted cordage, to be faſtened occaſionally round the maſt, as a ſupport to the puddening, whoſe uſe is to ſuſtain the weight of the fore and main-yards, in caſe the rigging or chains, by which thoſe yards are ſuſpended, ſhould be ſhot away in the time of battle.

DOM, or DON, a title of honour originally Spaniſh, though uſed occaſionally in other countries. It is equivalent to *maſter, ſir*; or *lord, monſieur, ſieur, mynheer, &c.*. In Portugal, nobody is allowed to aſſume the title of *dom*, which is a badge or token of nobility, without the king's leave. Dom is likewiſe uſed in France among ſome orders of religious. The word is formed from the Latin *domnus* or *dominus*; of which it is an abbreviature.

DOMAIN, the inheritance, eſtate, or poſſeſſion, of any one.

DOME, or DOOM, ſignifies, judgment, ſentence, or decree. The homagers oath, in the Black Book of Hereford, ends thus: ſo help me God at his holy *dome*, and by my trowthe.

DOME, in architecture, a ſpherical roof; or a work of a ſpherical form raiſed over the middle of a building, as a church, hall, pavilion, veſtibule, ſtair-caſe, &c. by way of crowning. They are uſually made round; though we have inſtances of ſquare ones; as thoſe of the Louvre; and others that are polygons, as that of the Jeſuits church in the Rue St. Antoine at Paris. They have uſually columns ranged around their outſides, both by way of ornament, and to ſupport the vault.

DOMES-DAY, or Dooms-Day *Book, Liber judiciarius vel cenſualis Agliæ*, the judicial book, or book of the ſurvey of England: a moſt ancient record made in the time of William the Conqueror; upon a ſurvey, or inquiſition, of the ſeveral counties, hundreds, tithings, &c. Its name is formed from the Saxon *dom*, *doom*, *judgment*, *ſentence*, and *day*, which has the ſame force; ſo that *dome day* is no more than a reduplicative, importing *judgment judgment*.

Doomſday ſignifies the lord's or king's proclamation, or advertiſement, to the tenants who hold under him; and agrees well with great part of the contents of this famous ſurvey. Obſervations on the Statutes, p. 190.

The deſign of the book is to ſerve as a regiſter, by which ſentence may be given in the tenures of eſtates; and from which that noted queſtion, whether lands be ancient demeſne, or not, is ſtill decided.

This book is ſtill remaining, fair and legible; conſiſting of two volumes, a greater and a leſs; the greater comprehending all the counties of England, except Northumberland, Cumberland, Weſtmoreland, Durham, and part of Lancaſhire, which were never ſurveyed; and except Eſſex, Suffolk, and Norfolk, which are comprehended in the leſſer volume, which concludes with theſe words, *Anno milleſſimo octageſimo ſexto ab incarnatione Domini, vigeſimo vero regis Wiſhelmi, facta eſt iſta deſcriptio non ſolum per hos tres comitatus, ſed etiam ulios.*

It is called *Liber judicialis*, becauſe a juſt and accurate deſcription of the whole kingdom is contained therein; with the value of the ſeveral inheritances, &c.

It was begun by five juſtices, aſſigned for that purpoſe in each county, in the year 1081, and finiſhed in 1086. Camden calls it *Gulielmi Librum cenſualem*, king William's tax-book.

This book was formerly kept under three locks and keys; one in the cuſtody of the treaſurer, and the others of the two chamberlains of the exchequer. It is now depoſited in the chapter-houſe at Weſtminſter, where it may be conſulted, on paying to the proper officers a fee of 6*s*. 8*d*. for a ſearch, and 4*d*. per line for a tranſcript.

DOMESTIC, from *domus*, houſe, a term of ſomewhat more extent than that of ſervant; the latter only ſignifying ſuch as ſerve for wages, as footman, lacquies, porters, &c. whereas domeſtic comprehends all who act under a man, compoſe his family, and live with him. Such are ſecretaries, chaplains, &c. Sometimes domeſtic goes farther, being applied to the wife and children.

DOMINICAL *Letter*, properly called Sunday letter, one of the ſeven letters of the alphabet ABCDEFG, uſed in almanacs, ephemerides, &c. to denote the Sundays throughout the year. The word is formed from *Dominica*, or *Dominicus dies*, Lord's day, Sunday. The dominical letters were introduced into the calendar by the primitive Chriſtians, in lieu of the nundinal letters in the Roman calendar. Theſe letters, we have obſerved, are ſeven: and that in a common year, the ſame letter ſhould mark all the Sundays will eaſily appear; inaſmuch as all the Sundays are ſeven days apart, and the ſame letter only returns in every ſeventh place. But in biſſextile, or leap year, the caſe is otherwiſe: for by means of the intercalary day, either the letters muſt be thruſt out of their places for the whole year afterwards, ſo, e. gr. as that the letter which anſwers to the firſt of March, ſhall otherwiſe anſwer to the ſecond, &c. or elſe the intercalary day muſt be denoted by the ſame letter as the preceding one. This latter expedient has been judged the better, and accordingly the Sundays after the intercalary day have another dominical letter.

DOMINICANS, an order of religious, called in ſome places Jacobins, and in others Predicants, or Preaching Friars, in England black friars. The Dominicans take their name from the founder Dominic de Guzman, a Spaniſh gentleman, born in 1170, at Calaroga, in Old Caſtile. He was firſt canon and archdeacon of Oſma; and afterwards preached with great zeal and vehemence againſt the Albigenſes in Languedoc, where he laid the firſt foundation of his order. It was approved of in 1215, by Innocent III. and confirmed in 1216, by a bull of Honorius III. under the title of St. Auguſtin; to which Dominic added ſeveral auſtere precepts and obſervances, obliging the brethren to take a vow of abſolute poverty, and to abandon entirely all their revenues and poſſeſſions; and alſo the title of preaching friars, becauſe public inſtruction was the main end of their inſtitution. The firſt convent was founded at Tholouſe by the biſhop thereof, and Simon de Montfort. Two years afterwards they had another at Paris, near the biſhop's houſe; and ſome time after, a third in the rue St. Jaques, St. James's ſtreet, whence the denomination of Jacobins. Juſt before his death, Dominic ſent Gilbert de Freſney, with twelve of the brethren, into England, where they founded their firſt monaſtery at Oxford, in the year 1221, and ſoon after another at London. In the year 1276, the mayor and aldermen of the city of London gave them two whole ſtreets by the river Thames, where they erected a very commodious convent, whence that place is ſtill called Black Friars, from the name by which the Dominicans were called in England.

DOMINIUM, Dominion, in the civil law, denotes the abſolute power, or property, of a thing, to uſe or diſpoſe of it how we pleaſe.

DONATION, Donatio, an act, or contract, whereby a man transfers to another, either the property, or the uſe, of the whole, or a part of his effects, as a free gift. A donation to be valid and complete, ſuppoſes a capacity both in the donor, and the donee; and requires conſent, acceptance and delivery; and by the French law regiſtry alſo.

DONATIVE, Donativum, a preſent made to any perſon; called alſo gratuity. The Romans made large donatives to their ſoldiers. Julia Pia, wife of the emperor Severus, is called, on certain medals, Mater Caſtrorum, becauſe of the care ſhe took of the ſoldiery, by interpoſing for the augmentation of their donatives, &c. Donative was properly a gift made to the ſoldiery; as Congiarius was that made to the people.

All biſhopricks in ancient time were donative by the king. Again, where the biſhop has a gift of the benefice, it is properly called a donative, becauſe he cannot preſent to himſelf.

DONAX, in conchology, the ninth genus belonging to the order of vermes teſtacea. The ſhell has two valves, with a very obtuſe margin in the fore-part. See the Syſtem and Synoptical Table, Genus 9.

DONOR, in law, he who gives lands or tenements, to another, in tail. As donee, is he to whom the ſame are given.

DOOR, in architecture, an aperture in a wall, to give entrance, and exit, in and out of the building, or ſome apartment thereof. Moſt of the obſervations that are applicable to windows may be applied to doors. See Syſtem of Architecture, on the Principles of the Art.

DOR, the Engliſh name for the common black beetle. Some alſo apply it to the duſty beetle, that flies about hedges in the evening.

DOREE, or *John* Doree, in ichthyology, a name given by us to a fiſh, called by authors the faber and gallus marinus. We have borrowed the name doree from the French; and, as to the word John, by ſome writers perfixed to it, it ſeems only a corruption of the French word *jaune*, *yellow*; expreſſing the colour of the ſides of this fiſh, which is a gold-yellow, by the phraſe *jaune dorée*; this has given us the words *John Dorée*, or by thoſe who ſpell yet worſe, *John Dory*, as we ſee it in ſome authors. See Zeus.

The fleſh is well taſted, and by many preferred to that of the turbot. It is caught in the Mediterranean and other ſeas, and is not uncommon on the Cornwall coaſt, and other of the Engliſh ſhores.

DORIC, in architecture, is the ſecond of the five orders; being that between the Tuſcan and Ionic. It is uſually placed upon the Attic baſe, though originally it had no baſe. The Doric order ſeems the moſt natural, and beſt proportioned, of all the orders; all its parts being founded on the natural poſition of ſolid bodies. Accordingly, the Doric is the firſt, and moſt ancient, of the orders of architecture, and is what gave the firſt idea of regular building. See Orders of Architecture, in the Syſtem, Plate II.

Doric, in grammar. The *Doric dialect* is one of the five dialects, or manners of ſpeaking, which obtained among the Greeks. See Dialect.

DORING, or Daring, among the ſportſmen, a term uſed to expreſs a method of taking larks, by means of a clap-net, and a looking glaſs. The looking glaſs is to be prepared in the following manner. Take a piece of wood, about an inch and a half thick, and cut it in form of a bow, ſo that there may be about nine inches ſpace between the two ends; and let it have its full thickneſs at the bottom, that it may receive into it a falſe piece; in the five corners of which, there are to be let in five pieces of looking glaſs. Theſe are to be fixed, that they may part their light upwards, and the whole machine is to be ſupported on a moveable pin, with the end of a long line fixed to it; and made in the manner of the children's play-thing of an apple and a plum-ſtone; ſo that the other end of the cord being carried through a hedge, the barely pulling it may ſet the whole machine of the glaſſes a-turning. This and the other contrivances are to be placed in the middle between the two nets. The larks fixed to the place, and termed calls, and the glittering of the looking glaſſes, as they twirl round in the ſun, invite the other larks down; and the cord that communicates with the nets, and goes through the hedge, gives the perſon behind an opportunity of pulling up the nets, ſo as to meet over the whole, and take every thing that is between them. The places where this ſort of ſporting ſucceeds beſt are open fields remote from any trees or hedges, except one by way of a ſhelter for the ſportſman, and the wind ſhould always be either in the front or back; for if it blows ſideways, it prevents the playing of the nets.

DORIS, a genus of worms, belonging to the ſixth claſs and the third order called vermes teſtacea. The body is oblong, flat beneath; creeping: mouth placed below; vent behind, ſurrounded with a fringe: two feelers, retractile. There are ſeveral ſpecies. The argo, or lemon doris, has an oval body, convex, marked with numerous punctures, of a lemon colour, the vent beſet with elegant ramifications. It inhabits different parts of our ſeas, called about Brighthelmſtone the ſea lemon. See Syſtem of Vermeology.

DORMANT, from *dormio*, *I ſleep*, is the herald's term for the poſture of a lion, or other beaſt, borne as ſleeping in a coat of arms. See Syſtem of Heraldry, Plate V.

DORMOUSE, in tetrapodology, the name of a ſpecies of wild mice, called alſo the ſleeper, claſſed under the genus of mouſe, in the order of glires, in the Linnæan ſyſtem. It has two cutting teeth in each jaw; four toes before, and five behind, and naked ears. There are two kinds of this creature, a larger and a ſmaller. See Mus.

DORONICUM, in botany, leopard's bane, a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants. For claſs and order ſee Syſtem of Botany, Sect. V. Plate V.

DORSAL, from *dorſum*, *back*, any thing that belongs to the back; as dorſal glands, dorſal nerves, dorſal muſcles.

Dorsi *Longiſſimus*, a muſcle common to the loins, and the back. It riſes from the upper part of the os ſacrum, ilium, and firſt vertebra of the loins; and in its beginning is confounded, if not the ſame, with the ſacrolumbaris. It runs upwards along the whole tract of the back, and is connected to every tranſverſe proceſs in its way; ending ſometimes in the firſt vertebra of the back, and ſometimes in the firſt of the neck. See Syſtem of Anatomy, Sect. XII.

DORSIFEROUS, or Dorsiparous *Plants*, from *dorſum*, and *fero*, *I bear*, are thoſe of the capillary kind; which are without ſtem, and bear their ſeeds on the backſide of their leaves.

DORSTENIA, contrayerva, in botany, a genus of the monogynia order, belonging to the tetandria claſs of plants. For claſs and order, ſee Syſtem of Botany, Sect. V. Plate IV.

DORSUM, in anatomy, is the hind part of the thorax; commonly tranſlated the back. The dorſum includes alſo the loins.

Dorsum *Manus*, and *Pedis*, is the outſide of the hand and foot; or that part oppoſite to the palm and ſole.

Dorsum *Naſi* is the ridge of the noſe, which runs the whole length of that part. In thoſe we call Roman noſes, the dorſum is higher, and more prominent, about the middle, than in the reſt; which part is called the ſpina, or ſpine.

DORT, *Synod of*, in eccleſiaſtical hiſtory, a national ſynod, ſummoned by authority of the ſtates-general, the provinces of Holland, Utrecht, and Overyſſel, excepted, and held at Dort in 1618. The moſt eminent divines of the United Provinces, and deputies from the churches of England, Scotland, Switzerland, Bremen, Heſſia, and the Palatinate, aſſembled on this occaſion, in order to decide the controverſy between the Gomariſts, or Calviniſts, and Arminians; the latter of whom were declared corrupters of the true religion.

But the authority of this ſynod was far from being univerſally acknowledged either in Holland or in England. The provinces of Frieſland, Zealand, Utrecht, Guelderland, and Groningen, could not be perſuaded to adopt their deciſions; and they were oppoſed by the authority of archbiſhop Laud, and king James I. in England. The reformed churches in France, though at firſt diſpoſed to give a favourable reception to the deciſions of this famous ſynod, in proceſs of time eſpouſed doctrines very different from thoſe of the Gomariſts; and the churches of Brandenburgh and Bremen would not ſuffer their doctors to be tied down to the opinions and tenets of the Dutch divines. The liberty of private judgment, with reſpect to the doctrines of predeſtination and grace, which the ſpirit that prevailed among the divines of Dort ſeemed ſo much adapted to diſcourage and ſuppreſs, acquired new vigour, in conſequence of the arbitrary proceedings of this aſſembly. Moſh. Eccl. Hiſt. vol. iv. p. 498.

DOSE, in pharmacy, &c. the quantity of a medicine to be taken at one time. The word is formed from the Greek δοσις, which ſignifies gift, or a thing given; from διδομι, *do*, *I give*.

A ſecret in phyſic is nothing, unleſs the doſe be known. In authors, and diſpenſatories, that deſcribe the ſame remedy, frequently the doſe is different; which occaſions a great difference in its effect. Dr. Cockburn has given us an eſſay towards determining the doſes of purgative medicines, on mechanical principles. Several attempts have been made to aſcertain the proportional doſes for the different ages and conſtitutions of patients; but, after all than can be ſaid on this ſubject, much muſt be left to the judgment of the perſon who adminiſters the medicine. The following general proportions may be obſerved, though by no means intended for exact rules. A patient between 20 and 14 may take two-thirds of the doſe ordered for an adult; from 14 to 9. one half; from 9 to 6, one third; from 6 to 4, one fourth; from 4 to 2, one ſixth; from 2 to 1, a tenth; and under 1, a twelfth. Buchan's Dom. Med. App. p. 595.

DOSITHEANS, in church hiſtory, a ſect among the Hebrews, being one of the branches of the Samaritans. They abſtained from eating any creature that had life; and were ſo ſuperſtitious in keeping the ſabbath, that they remained in the ſame place and poſture wherein that day ſurpriſed them, without ſtirring till the next day. They married but once, and a great number never married. Doſitheus, their founder, being diſſatisfied among the Jews, retired to the Samaritans, who were reputed heretics, and invented another ſect; and to make it more authentic, he went into a cave, where, by too long abſtinence, he killed himſelf. The name of Doſitheans was alſo given to ſome of the diſciples of Simon Magus.

DOTE *Aſſignando*, in law, a writ that lay for a widow, where it was found by office, that the king's tenant was ſeiſed of tenements in fee, or fee tail, at the day of his death; and that he held of the king in chief, &c. in which caſe, the widow came into the chancery, and there made oath, that ſhe would not marry without the king's leave. Anno 16 Edw. III. c. 4. And hereupon ſhe had this writ to the eſcheator; for which ſee Reg. of Writs, fol. 297. and Fitz. Nat. Br. fol. 263. Theſe widows are called the king's widows.

Dote *unde nihil habet*, in law, a writ of dower that lies for the widow againſt the tenant, who bought land of her huſband in his life time, whereof he was ſolely ſeiſed in fee-ſimple or fee-tail, in ſuch ſort, as the iſſue of them both might have inherited.

DOTTEREL, charadrius, in ornithology, ſee Charadrius.

DOUBLE; two of a ſort, one correſponding to the other.

Double *Banked*, in ſea language, denotes the ſituation of the oars of a boat, when two oppoſite ones are managed by rowers ſeated on the ſame bench, or thwart. The oars are alſo ſaid to be double banked when two men row upon every ſingle one.

Double *Children*, Double *Cats*, Double *Pears*, &c. inſtances oft are frequent in the Philoſophical Tranſactions, and elſewhere. See Monster.

Sir John Floyer, in the ſame tranſactions, giving an account of a double turkey, furniſhes ſome reflections on the production of double animals in general. Two turkeys, he relates, were taken out of an egg of the common ſize, when the reſt were all hatched, which grew together by the fleſh of the breaſt bone: but, in all other parts, were diſtinct. They ſeemed leſs than the ordinary ſize, as wanting bulk, nutriment, and room for their growth, which latter, too, was apparently the occaſion of their coheſion. For, having too diſtinct cavities in their bodies, and two hearts, they muſt have ariſen from two cicatriculas; and conſequently, the egg had two yolks, which is no uncommon accident. He had a dried double chicken: he aſſures us, that though it had four legs, four wings, &c. it had but one cavity in the body, one heart, and one head; and that this, conſequently, was produced from one cicatricula. So, Paræus mentions a double infant with only one heart: in which caſe, the original, or ſtamen of the infant, was one, and the veſſels regular: only the nerves and arteries towards the extremities, dividing into more branches than ordinary, produced thoſe double parts. The ſame is the caſe in the double flowers of plants, occaſioned by the richneſs of the ſoil. So it is in the eggs of quadrupeds, &c. There are, therefore, two reaſons of duplicity in embryos: 1. The conjoining, or connection of two perfect animals; and, 2. An extraordinary diviſion, and ramification of the original veſſels, nerves, arteries, &c.

Double *Horizontal Dial*, one with a double gnomon, whereof one points out the hour on the outward circle, and the other ſhews the hour on the ſtereodraphic projection drawn upon it. This dial finds the meridian, hour, the ſun's place, riſing, ſetting, &c. and many other propoſitions of the globe. See Treatiſe on Dialling, Sect. V.

Double *Fichê*, or Double *Fichy*, in heraldry. A croſs is denominated *double fichê*, when the extremities are pointed at each angle; that is, when each extremity has two points: in contradiſtinction to *fichê*, where the extremity is ſharpened away to one point. Gibbon expreſſes it by an octagonal croſs, the two points whereof at each extremity are parted inwards by a ſmall ſpace of a line; by which it is diſtinguiſhed from the croſs of Malta, the two points whereof proceed from a third point, or acute angle between them.

Double *Letter*, in grammar, a letter, which has the force and effect of two: as the Hebrew *Tſade*, which is equivalent to *T* and *S*; or the Greek ξ, or Latin *x*, &c. Theſe letters are evidently equal to two: when we pronounce the Latin *axis*, or the Engliſh *axillary*, we give the *x* the ſame ſound, as if it were written with two *cc*, *accis*, *accillary*; or a *c* and *s*, *acſis*, *acſillary*. The Greeks have three, Ζ, Ξ, Ψ; the Latins only two, X and Z; and moſt of the modern languages have the ſame.

Double *Point*, in the higher geometry. When all the right lines tending the ſame way with the infinite leg of any curve, do cut it only in one point (as happens in the ordinates of the Carteſian, and the cubical parabola) and in the right lines which are parallel to the abſciſſes of hyperbolas, and parabolas, then you are to conceive, that thoſe right lines paſs through two other points of the curve, placed, as it may be ſaid, at an infinite diſtance. Which coincident interſection, whether it be a finite, or an infinite diſtance, ſir Iſaac Newton calls the double point.

Double *Veſſel*, in chymiſtry, is when the neck of one bolthead, or mattraſs, is put, and well luted, into the neck of another. Of theſe there are divers kinds and forms, uſed in the circulation of ſpirits, in order to their being exalted, and refined, as high as can be.

DOUBLETS, among lapidaries, denote cryſtals wrought into ſuch a form, and ſo coloured, that the ſurfaces of two pieces thus coloured being laid together, might produce the ſame effect as if the whole ſubſtance of the cryſtal had been tinged. For this purpoſe, two plates of cryſtal muſt be cut in the manner of a brilliant, and fitted ſo exactly, that no diviſion can appear when they are laid together. The upper part muſt be poliſhed ready for ſetting, and then the colours may be put between them by the following proceſs: take of Venice, or Cyprus turpentine, two ſcruples, and add to it one ſcruple of the grains of pure maſtic powdered. Melt them together in a ſilver or braſs ſpoon, ladle, or other veſſel, and mix with them any of the coloured ſubſtance propoſed, well powdered. Warm the doublets to the ſame degree of heat with the mixture, and paint the upper ſurface of the lower part, and put the upper one inſtantly upon it, preſſing them evenly together. When the cement is quite cold, ſcrape the edges, and let the doublets be ſkilfully ſet, by carrying the mounting over the joint, ſo that the two pieces may be well ſecured from ſeparating. The colour of the ruby may be imitated, by mixing a fourth part of carmine with fine crimſon lake; the ſapphire and amethyſt may be counterfeited by mixing very bright Pruſſian blue with a ſmall quantity of crimſon lake; the emerald may be imitated by diſtilled verdigriſe, with a little powdered aloes; the garnet may be counterfeited by dragon's blood, the brightneſs of which may be improved by the addition of a ſmall quantity of carmine; the yellow topazes may be imitated by mixing the powdered aloes with a little dragon's blood. Glaſs may be alſo prepared in the ſame manner. Doublets may be eaſily diſtinguiſhed, by holding them betwixt the eye and the light, in ſuch poſition, that the light may paſs through the upper part and corner of the ſtone; which will then ſhew ſuch parts to be white, and that there is no colour in the body of the ſtone. Handmaid to the Arts, vol. ii. p. 328, &c.

Doubling, in a military ſenſe, is the putting of two ranks, or files of ſoldiers, into one. When the word of command is, double your ranks, the ſecond, fourth, and ſixth ranks are to march up into the firſt, third, and fifth; ſo that of ſix ranks they make but three, leaving double the interval there was between them before. But it is not ſo when they double the half-files, becauſe then three ranks ſtand together, and the three others come up to double them; that is, the firſt, ſecond, and third, are doubled by the fourth, fifth, and ſixth; or on the contrary. Double your files, directs each to march to that next to it on the right or left, according to the word of command; in which caſe the ſix ranks are turned into twelve, the men ſtanding twelve deep; the diſtance between the files being now double of what it was before.

Doubling *a Cape*, or *Point*, in navigation, ſignifies the coming up with it, paſſing by it, and leaving it behind the ſhip.

The Portugueſe pretend to be the firſt that ever doubled the Cape of Good Hope, under their admiral Vaſquez de Cama; but we have accounts in hiſtory, particularly in Herodotus, of the Egyptians, Carthaginians, &c. having done the ſame long before them.

Doubling *Upon*, in a naval engagement, is the art of encloſing any part of a hoſtile fleet between two fires, or of cannonading it on both ſides. It is uſually performed by the van or rear of that fleet which is ſuperior in number taking the advantage of the wind; or of its ſituation, and tacking, or veering round the van or rear of the enemy, who are thereby expoſed to great danger, and can ſcarcely avoid being thrown into a general confuſion.

DOUBLINGS, in heraldry, the lining of mantles over the arms in an atchievement.

DOUBLON, **Dubloon**, a Spaniſh and Portugueſe coin, being the double of a piſtole. There are alſo double dubloon, formerly current among us for three pounds twelve ſhillings.

DOUBTING, the act of with-holding a full aſſent from any propoſition; on ſuſpicion, that we are not thoroughly appriſed of the merits thereof; or from our not being able peremptorily to decide between the reaſons for, and againſt it. The ſceptics and academics doubt of every thing; the character of their philoſophy is, not to allow any thing for truth; but to with-hold the aſſent, and keep the mind free, and in ſuſpenſe. The Epicureans truſt their ſenſes, and doubt of their reaſon: their leading principle is, that our ſenſes always tell truth; that they are the firſt and only criterions of truth; and that if you go ever ſo little from them, you come within the proper province of doubting. The Carteſians, on the contrary, of all things bid us doubt our ſenſes; they are perpetually inculcating the deceitfulneſs of our ſenſes; and tell us, that we are to doubt of every one of their reports, till they have been examined, and confirmed by reaſon.

DOUCINE, in architecture, a moulding, or ornament, on the higheſt part of the corniche, in form of a wave, half convex, and half concave.

DOVE, the Engliſh name of a bird of the pigeon kind, belonging to the order Columbine. It ſeldom flies ſingle, but in large flocks, and builds on trees; its food is ivy berries, and other vegetable matter. They begin to cooe in March, when they pair, and leave off in the beginning of winter. See Plate III.

Dove *Tail*, in carpentry, the ſtrongeſt of all the kinds of jointings; wherein the tenon, or piece of wood that enters the other, goes widening to the extreme, and ſo cannot be drawn out again, becauſe the tip, or extreme, is bigger than the whole. It has its denomination from the reſemblance the tenon bears to a dove's tail. The French call it *queue d'aronde*, *ſwallow's tail*; which name the Engliſh themſelves alſo retain in fortification.

DOVELLA, in ichthyology, a name given by the Maſſilians to the fiſh called the donzellina by the Italians: it is the julia, or julis, of authors; and, according to the Artedian ſyſtem, it is a ſpecies of the labrus. That author diſtinguiſhes it by the name of the labrus of variegated colours, with two large teeth in the upper jaw. See **Labrus**.

To **DOUSE**, in ſea language, is to lower ſuddenly, or ſlacken; and it is applied to a ſail in a ſquall of wind, an extended hawſer, &c.

DOWAGER, **Dotissa** (q. d. a widow endowed, or that has a jointure), a title or addition, applied to the widows of princes, dukes, earls, and perſons of high rank only.

Dowager, *Queen*. See **Queen**.

DOWER, **Dotarium**, **Doarium**, or **Dos**, a portion of lands, or tenements, which a widow enjoys for term of life, from her huſband, in caſe ſhe ſurvives him; and which, at her death, deſcends to their children. But ſhe muſt have been the wife of the party at the time of his deceaſe; or not divorced *a vinculo Matrimonii*; nor, if ſhe has eloped from her huſband, and lives with an adulterer, ſhall ſhe be entitled to dower, unleſs her huſband be voluntarily reconciled to her. The widows of traitors are alſo barred of their dower by 5 and 6 Ed. VI. cap. 11. but not the widows of felons. An alien cannot be endowed, unleſs ſhe be queen conſort, and if a woman levies a fine with her huſband, or if a common recovery be had with the huſband and wife of the huſband's lands, ſhe is barred of her dower. A widow clear of theſe impediments, is by law entitled to be endowed of all lands and tenements, of which her huſband was ſeiſed in fee ſimple or fee tail, at any time during the coverture; and of which any iſſue ſhe might have had, might by poſſibility have been heir. Our law books diſtinguiſh five kinds of dower; viz. *dower per legem communem*; *per conſuetudinem*; *ex aſſenſu patris*; *ad oſtium eccleſiæ*; and *de la plus belle*. But the two firſt are now only in uſe.

Dower *by the common Law*, is a third part of ſuch lands as the huſband was ſole ſeiſed of in fee during the marriage; which the wife is to enjoy during her life, and for which there lies a writ of error.

Dower *by Cuſtom* gives the wife, in ſome places, half her huſband's lands, ſo long as ſhe lives ſingle, as in gavel-kind. And as cuſtom may enlarge, ſo that the widow may have the whole during life, which is called her *free bench*, ſo may it abridge dower, and reſtrain it to a fourth part.

In **Dower** *ex aſſenſu Patris*, and *ad oſtium Eccleſiæ*; the wife may have ſo much dower as ſhall be aſſigned, or agreed upon; but it ought not to exceed the third part of the huſband's lands. If this be done before marriage, it is called a jointure.

DOWN, in natural hiſtory, denotes the firſt feathers of geeſe, with which beds and pillows are ſtuffed. The cottony ſubſtance on the tops of thiſtles, &c. is alſo thus called.

DOWNS, a bank, or elevation, of ſand, which the ſea gathers and forms along its ſhores; and which ſerves it as a barrier.

Downs, a famous road for ſhips, along the eaſtern coaſt of the county of Kent; from Dover to the North Foreland. This road has excellent anchorage, and is well defended by the caſtles of Sandwich, Deal, and Dover.

DOWNY, ſomething partaking of the nature of down. Thus ſome leaves and fruit, &c. are ſaid to be covered with a downy matter.

DOWRY, **Dos**, is properly the money, or fortune, which the wife brings her huſband in marriage, to have the uſe of it, during her marriage, towards ſupporting the charge thereof.

It is otherwiſe called *maritagium*, *marriage goods*; by the Romans *dos*; and it differs from *dower*. See **Dower**. Among the Germans, it was anciently cuſtomary for the huſband to bring a dowry to his wife.

Dowry is alſo uſed, in a monaſtic ſenſe, for a ſum of money given along with a maid, upon entering her in ſome religious order. In France, the dowry of perſons entering a monaſtery, to make profeſſion of a religious life, is limited by law. That, e. gr. given upon entering a monaſtery of Carmelites, Urſulines, and others, not regularly founded, but eſtabliſhed ſince the year 1600, by letters patent, muſt not exceed the ſum of 8000 livres, in towns where parliaments are held; nor 6000, in other places.

DOXOLOGY, an appellation given by the Greeks to the fourteenth verſe of the ſecond chapter of St. Luke, *Glory be to God in the higheſt*, &c. becauſe beginning with the Greek word *δοξα*, *glory*. This they diſtinguiſh by the name of *great doxology*; and the *Gloria Patria*, *Glory be to the Father*, they call the *leſs doxology*, as beginning with the ſame word *δοξα*. Philoſtorgius, lib. iii. n. 13. gives three formulas of the *leſſer doxology*. The firſt is, *Glory be to the Father, and to the Son, and to the Holy Ghoſt*; the ſecond, *Glory be to the Father, by the Son, in the Holy Ghoſt*; and the third, *Glory be to the Father, in the Son, and the Holy Ghoſt*. Sozomen, and Nicephorus, give a fourth: viz. *Glory be to the Father, and the Son, in the Holy Ghoſt.*

The firſt of theſe doxologies is that in common uſe throughout the weſtern church. It was firſt inſtituted about the year 350, by the Catholics of Antioch, then called Euſtathians. The three others were compoſed by the Arians; the ſecond was that of Eunomius, and Eudoxus, and which was approved by Philoſtorgius. The three were all made about the year 341, in the council of Antioch, when they firſt began to diſagree among themſelves. Philoſtorgius aſſures us, that Flavian, afterward patriarch of Antioch, was the author of the firſt, or catholic doxology; but Sozomen, and Theodoret, ſay nothing of it; and Philoſtorgius's ſingle authority is hardly ſufficient.

There were anciently very great diſputes, and principally at

Antioch, as to the form of doxology; that moſtly uſed among the orthodox was, the ſame as ſtill obtains; the reſt were affected by the Arians, and other Antitrinitarians; yet St. Baſil, in his book on the Holy Spirit, defends the ſecond as orthodox, and legitimate; and it is certainly more agreeable to Scripture authority; to which we muſt ultimately appeal, as the only infallible rule of our devotion, as well as of our conduct: and it has been urged, that no inſtance of the former doxology occurs in the New Teſtament.

Some authors write hymnology as ſynonymous with doxology; but there is a difference: hymnology is applied to pſalms, or the recitation of pſalms; and doxology only to the little verſe. *Glory be to the Father*, &c. repeated at the end of each pſalm.

DRABA, in botany, a genus of the ſiliculoſa order, belonging to the tetradynamia claſs of plants. For the Claſs and Order, ſee Syſtem of BOTANY, Sect. V. Plate V.

DRABS, in the Engliſh ſalt-works, a name given to a ſort of wooden caſes in which the ſalt is put, as ſoon as it is taken out of the boiling pan. Theſe are partitions like ſtalls made for horſes; they are lined on three ſides and at the bottom with boards, and at the front have a ſliding board to put in or take out occaſionally. Their bottoms are made ſhelving, being higheſt at the backſide, and gradually inclining forwards; by which means the ſaline liquor that remains mixed with the ſalt eaſily drains out from it, and the ſalt in three or four days becomes ſufficiently dry, and is then taken out and laid up in large heaps for ſale. In ſome places they uſe cribs inſtead of the drabs.

DRACHM, or DRAM, is a weight uſed by our phyſicians, containing juſt ſixty grains, or three ſcruples, or the eighth part of an ounce troy, and the ſixteenth of an ounce avoirdupois.

DRACO, dragon, in aſtronomy, a conſtellation of the northern hemiſphere; whoſe ſtars, according to Ptolemy, are 31; according to Tycho, 32; according to Hevelius, 40; according to Bayer, 33; and according to Mr. Flamſtead, 80. See Syſtem of ASTRONOMY, Sect. VIII.

DRACO, the dragon, a genus belonging to the order of amphibia reptilia. The characters of which are theſe: it has four legs; a cylindrical tail, and two membranaceous wings, radiated like the fins of a fiſh, by which he is enabled to fly, but not to any great diſtance at a time. There are two ſpecies, 1. The volans, or flying dragon, with the wings entirely diſtinct from the fore legs; it is found in Africa and the Eaſt Indies. 2. The præpos, with the wings fixed to the fore legs; it is a native of America. They are both harmleſs creatures, and feed upon flies, ants, and ſmall inſects.

DRACO *Volans*, in meteorology, a fiery exhalation, frequent in marſhy and cold countries. It is moſt common in ſummer; and though principally ſeen playing near the banks of rivers, or in boggy places, yet ſometimes mounts up to a conſiderable height in the air, to the no ſmall terror of the amazed beholders; its appearance being that of an oblong, ſometimes roundiſh, fiery body, with a long tail. It is entirely harmleſs, frequently ſticking to the hands and cloaths of people, without injuring them in the leaſt.

DRACONTIUM, a genus of the polyandria order, belonging to the gynandria claſs of plants. See Syſtem of BOTANY, Sect. V. Plate V.

DRACUNCULI, in medicine, a ſort of long and ſlender worms, which breed in the muſcular fleſh of the arms, legs, &c. and from their being more frequent in ſome parts of Guinea than elſewhere, are called by many Guinea-worms.

The microſcope has put it paſt doubt, that they are real living animals, of an aſh colour, having two long horns, two large round eyes, and a long tail, terminated with a tuft of hair. The common way of getting out theſe worms is by the point of a needle; to prevent their forming again the uſual way is to waſh the parts with wine or vinegar, allum, nitre, or common ſalt, or with a ſtrong lixivium of oak aſhes, and afterwards anointing them with an ointment of the common kind uſed for ſcorbutic eruptions, with a ſmall mixture of quickſilver.

DRAGON, in aſtronomy. See DRACO.

DRAGON *Beams*, in architecture, are two ſtrong braces or ſtruts, which ſtand under a breaſt-ſummer, and meet in an angle on the ſhoulder of the king-piece.

DRAGON'S *Blood*, *ſanguis draconis*, in medicine, a reſinous ſubſtance brought from the Eaſt, in oval drops, wrapped up in flag leaves, of conſiderable uſe, as an agglutinant and deſiccative, againſt fluxes, both alvine and uterine, and ulcerations internal and external, &c. It derives its name dragon's blood from the redneſs of the colour, and gives its name dragon to the tree that yields it. The genuine dragon's blood is the juice, or reſin, of a large tree, called *draco arbor*, the *dragon tree*, reſembling the palm, growing in Africa, and America, as well as in China. It is a good aſtringent; and is uſed in hæmorrhages and dyſenteries; as alſo to faſten the teeth, and ſtrengthen the gums. A ſolution of dragon's blood in ſpirit of wine is uſed for ſtaining marble, to which it gives a red tinge, which penetrates more or leſs deeply, according to the heat of the marble during application. But for fine deſigns, the marble ſhould be cold, becauſe it ſpreads while it ſinks. Mr. Du Fay ſays, that by adding pitch to this ſolution, the colour may be rendered deeper. There is alſo a counterfeit dragon's blood, made of the gum of the cherry, or almond tree, diſſolved, and boiled in a tincture of Brazil wood; but this is of no uſe, except for external diſeaſes of horſes. Theſe adulterated reſins are diſtinguiſhed from the true by their diſſolving in water, and crackling in the fire without burning.

DRAGON *Fly*, in entomology, the Engliſh name of a very large genus of four winged flies, called by us adder-flies, and dragon-flies. They belong to the order of neuroptera in the Linnæan ſyſtem; they are characteriſed by having jaws, by antennæ ſhorter than the thorax, by extended wings, and by the male's tail being terminated by a hooked kind of forceps. See LIBELLA.

Theſe flies have all two very large and reticulated eyes, covering the whole ſurface of the head, which are a beautiful object for the microſcope. They fly very ſwiftly, and prey upon the wing, being of great uſe to mankind, and clearing the air of innumerable little flies. They are produced of ſeveral ſpecies of ſix-legged worms living in the waters, and figured by ſeveral other authors, under the name of *pulices*, and *locuſtæ aquaticæ*.

Moſt of theſe ſpecies are found in Auguſt and September, in our fields and gardens, eſpecially near places where there are waters, as they have their origin for worms living in that element. The great ones uſually live all their time about waters, but the ſmaller are common among hedges, and the ſmalleſt of all are moſt frequent in gardens. The ſmaller kinds often ſettle upon buſhes or upon the ground; but the large ones are almoſt always upon the wing, ſo that it is very difficult to take them. The manner of this inſect's coupling with the female is a thing that has attracted the obſervation and admiration of multitudes, as they are frequently ſeen, in the hotter months, in that ſtate, flying together about the edges of waters.

Mr. Homberg, of the Academy of Paris, has taken great pains to inform the world of the whole ſecret of this ſtrange coitus, and of ſeveral other remarkable particulars in regard to the creature. The part to which the wings are fixed is called the breaſt in animals of this kind; but in this creature the lungs are not ſituated there, but in the middle of the belly, which is ſeen continually riſing and falling at inſpiration and expiration. The laſt joint of the body of the male is a ring containing the anus, and this is furniſhed with two pair of hooks; the one pair outward and larger, the other inward and ſmaller: theſe the creature is able to open and ſhut as lobſters do their claws. The extremity of the belly of the female ſeems to conſiſt of two tubes, or pipes, one placed upon the other; the upper one is the anus, at which it voids its excrements; the under one is the female part of generation, and the entrance of the womb of the animal. When the male of this ſpecies finds the female ſitting upon a leaf, or ſtick, he ſeizes her as ſhe flies, taking faſt hold of her with the hooks at the anus by the neck, or that part which joins the head to the breaſt, and immediately flies away with her, holding her fixed by the neck to the end of his tail.

The male does not carry his bride far before he ſettles himſelf upon ſome plant, and raiſes his tail ſo, that the female may be brought to ſit eaſily under him upon the ſame plant. As ſoon as the female is thus ſeated, ſhe turns up her tail, and brings it between the legs of the male, then places it to a certain part of the breaſt of the male, in which are the organs of generation in that ſex. All this while the male keeps his hold of her neck with his forceps, or hooks. They uſually remain in this poſture about three minutes; and after that the male gently raiſing up his breaſt, they become ſeparated, and leaving the hold he had on her neck, at the ſame time, he flies away as he pleaſes. The female uſually remains on the place for half a quarter of an hour, and then ſhe flies away alſo. Mr. Homberg having obſerved the coupling of theſe animals thus far, was determined to examine the organs uſed in it by diſſection. To this purpoſe he caught ſeveral of them, and on the whole collected ſeveral curious obſervations, which may be ſeen in Mem. Acad. Par. 1699.

DRAGONNEE, in heraldry. A lion dragonneé, is where the upper half reſembles a lion; the other half going off like the hind part of a dragon.

DRAGOONS, in war, an order of ſoldiery, who march on horſeback, and fight on foot, though ſometimes, too, on horſeback. Dragoons are divided into brigades, as the cavalry, and each regiment into troops; each troop having a captain, lieutenant, cornet, quarter-maſter, two ſerjeants, three corporals, and two drums. Some regiments have hautboys. They are very uſeful on any expedition that requires diſpatch; for they can keep pace with the cavalry, and do the duty of infantry: they encamp generally on the wings of the army, or at the paſſes leading to the camp; and ſometimes they are brought to cover the general's quarters: they march in the front and rear of the army.

DRAGS, in the ſea language, is uſed for whatever hangs over the ſhip in the ſea, as ſhirts, coats, or the like; and boats when towed, or whatever elſe that, after this manner, may hinder the ſhip's way when ſhe ſails.

DRAIN, or DREIN, in the military art, a trench made to draw the water out of a moat, which is afterwards filled with hurdles and earth, or with faſcines, or bundles of ruſhes and planks, to facilitate the paſſage over the mud.

DRAINS, a name given in the fen countries to certain large cuts, or ditches, of twenty, thirty, nay ſometimes forty feet wide, carried through the marſhy ground to ſome river, or other place capable of diſcharging the water they carry out of the fen lands. Moſt of theſe drains are made in our fen countries by a body of men called the undertakers, whoſe reward is one third of the ground they drain. They alſo erect ſluices at a great expence, often not leſs than two thouſand pounds each. Yet theſe, with all the care they employ in erecting them, are ſubject to be blown up by the vaſt weight of water that lies upon them when the lands are overflown. Some of theſe ſluices have two or more pair of doors, of ſix, eight, or ten feet high, which ſhut when the water in the river is higher than in the drains, by the weight and force of it; and ſo *è contra*, throw out a body of eight feet ſquare of water for about ſix or ſeven hours during the ebb. The real uſe of theſe drains is very evident from the preſent ſtate of the land where they are cut, and that of it before. In Camden's time all this was bog, and now it is all firm land. The country about Crowland was in that author's time ſo ſoft, that it was not paſſable by carriages; and thus grew a witticiſm upon it, that all the carts that entered this town were caſed on the wheels with ſilver; but this is now ſo firm ground, that carriages of any kind paſs over it. The duck-ponds uſed to be called the fen corn-fields, and they now are ſuch in reality, their bottoms being dry, and producing oats, and rape-ſeed, or cole-ſeed, with great increaſe. Phil. Tranſ. Nº 223.

Drains are alſo more generally uſed to carry off the ſuperfluous moiſture from wet and marſhy lands. For this purpoſe a deep drain muſt be cut in the loweſt part, ſo as to reach the bed, whether of gravel or ſand, through which the water flows. See Syſtem of AGRICULTURE, Sect. IX.

DRAMA, in poetry, a piece, or poem, compoſed for the ſtage. The word is Greek, δραμα, which literally ſignifies *action*; becauſe in dramas, or dramatic poems, they act, or repreſent actions, as if they really paſſed. A drama, or as we popularly call it, a play, is a compoſition either in proſe or verſe, conſiſting, not in the ſimple recitation, but in the actual repreſentation of an action. Our dramas are, tragedies, comedies, operas, and farces.

DRAMATIC, in poetry, is an epithet given to pieces written for the ſtage.

DRANK, a name given by our farmers to the great wild oats, Theſe are often very troubleſome to the ploughed lands, eſpecially after wet ſeaſons and much froſt. Many to deſtroy this weed ſow the land with black oats, which being ripe much ſooner than the ſeeds of this plant, are cut down before it can ſow itſelf for another year; eſpecially if they are cut a little the earlier, which will do them no harm, if they be ſuffered to lie a while upon the ground afterwards, for the grain to ſwell before they are carried in. But, in general, when ploughed lands begin to run to theſe weeds and thiſtles, it is a token to the farmer that it is time to fallow them, or elſe to ſow them with hay-ſeed, and make paſtures of them. The ſowing beans upon a land ſubject to theſe weeds is alſo a good method, becauſe the farmer may ſend in his ſheep when they are about three inches high, which will eat up the drank, and all the other weeds, and will not hurt the beans. The general method is to put twenty ſheep to an acre; but they muſt be put in only in dry weather, and not left too long.

DRAPERY, in drawing and ſculpture, the repreſentation of the garments, or clothing of human figures. The word is French, *draperie*, formed from *drap*, *cloth*. In the general ſenſe, drapery includes not only the garments, but alſo the tapeſtry, linens, and moſt other things that are not carnations, nor landſcapes. The art of drapery conſiſts chiefly in three points, viz. the ordering of the folds or plaits; the different quality of the ſtuffs; and the variety of their colours. M. de Piles give abundance of good obſervations relating to drapery. Their firſt effect, he obſerves, and that which the painter ought to have principally in view, is, that they expreſs the thing they are ſuppoſed to cover; and they muſt never be made to adhere, and ſtick to the parts of the body; a great lightneſs, and motion of the drapery, are only proper for figures in great agitation, or expoſed to the wind. The nudities of the figures ſhould always be deſigned, before the painter proceeds to the draperies. Titian, Paul Veroneſe, and Vandyke, excelled in draperies. See Treatiſe of DRAWING.

DRASTIC, from δραω, *I act*, a ſtrong and powerful medicine; more particularly, a purgative that works with ſpeed and vigour; as jalap, ſcammony, and the other ſtronger cathartics.

DRAUGHT, in trade, is an allowance made in the weight of commodities.

DRAUGHT is alſo uſed ſometimes for a bill of exchange, and commonly for an order for the payment of any ſum of money due, &c. Then the perſon who gives the order is ſaid to draw upon the other.

DRAUGHT, or, as it is pronounced, draft, in architecture, the figure of an intended building deſcribed on paper: wherein are laid down, by ſcale and compaſs, the ſeveral diviſions and partitions, of the apartments, rooms, doors, paſſages, conveniencies, &c. in their due proportion. It is uſual, and even exceedingly convenient, before a building is begun to be raiſed, to have draughts of the ichnography, or ground-plot of each floor, or ſtory; as alſo of the form and faſhion of each front, with the windows, doors, ornaments, &c. in an orthography, or upright. Sometimes the ſeveral fronts, &c. are taken, and repreſented in the ſame draught, to ſhew the effect of the whole building: this is called a ſcenography, or perſpective.

DRAUGHT-*Compaſſes*, thoſe provided with ſeveral moveable points, to draw fine draughts in architecture, &c.

DRAUGHT-*Hooks*, are large hooks of iron fixed on the cheeks of a cannon-carriage, two on each ſide, one near the trunnion-hole, and the other at the train, and are called the fore and hind draught-hooks.

DRAW. A ſhip is ſaid to draw ſo much water, according to the number of feet ſhe ſinks into it. Thus, if fifteen feet from the bottom of her be under water, or if ſhe ſink into the water fifteen feet perpendicularly, ſhe is ſaid to draw fifteen feet water; and according as ſhe draws more, or leſs, ſhe is ſaid to be of more, or leſs draught; and that this may be more readily known, the feet are marked on the ſtern and ſtern-poſt regularly from the keel upwards. Drawing denotes alſo the ſtate of the ſail, when it is inflated with the wind, ſo as to advance the veſſel in her courſe.

DRAW-*Back*, in commerce, a rebate, or diſcount, upon the price of commodities, purchaſed on certain conditions. Draw-back is more particularly uſed to denote certain duties, either of the cuſtoms or of exciſe, that are allowed upon the exportation of ſome of our own manufactures, or upon certain foreign commodities that have paid a duty at importation. The oaths of the merchants importing or exporting are required, to obtain the draw-back of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties; and theſe may be made by the agent or huſband of any corporation or company, or by the known ſervant of any merchant, uſually employed in making his entries, and paying his cuſtoms. 2 and 3 Ann. cap. 9. With reſpect to foreign goods entered outwards, if leſs in quantity or value be fraudulently ſhipped out than is expreſſed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no draw-back is to be allowed for the ſame. Foreign goods exported by certificate, in order to obtain the draw-back, not ſhipped or exported, or re-landed in Great-Britain, unleſs in caſe of diſtreſs, to ſave them from periſhing, which muſt be immediately ſignified to the officers of the cuſtoms, are to loſe the benefit of the draw-back, and are forfeited, or their value, with the veſſels, horſes, carriages, &c. employed in the relanding of them; and the perſons concerned in re-landing them, or by whoſe privity they are re-landed, or into whoſe hands they ſhould knowingly come, are to forfeit double the amount of the draw-back. 13 and 14 Car. II. cap. 11. This is to be paid for within five years after the offence. And the ſeizure of the horſes, &c. may be adjuſted by two or more juſtices of the peace. 6 Geo. I. cap. 21. 8 Geo. I. cap. 18. and 11 Geo. I. cap. 29.

Officers of the cuſtoms conniving at, or aſſiſting in any fraud relative to certificate goods, beſides other penalties, are to forfeit their office, and to ſuffer ſix months impriſonment, without bail or mainprize; as are alſo maſters or perſons belonging to the ſhips employed in this buſineſs. 8 Ann. cap. 13. Bonds given for the exportation of certificate goods to Ireland muſt not be delivered up, nor draw back allowed for any goods, till a certificate under the hands and ſeals of the comptroller, or collector, &c. of the cuſtoms of ſome port in Ireland be produced, teſtifying the landing, which certificate muſt be produced in ſix months from the date of the bond. 8 Ann. cap. 13. 5 Geo. I. cap. 11. 9 Geo. I. cap. 8. 2 Geo. II. cap. 28. See CUSTOMS.

DRAW *Bridge*, a bridge made after the manner of a floor, to be drawn up, or let down, as occaſion ſerves, before the gate of a town or caſtle.

DRAW *Net*, a kind of net for taking the large ſort of wild fowl, which ought to be made of the beſt packthread, with wide meſhes: they ſhould be about two fathoms deep, and ſix long, verged on each ſide with a very ſtrong cord, and ſtretched at each end on long poles. It ſhould be ſpread ſmooth and flat upon the ground, and ſtrewed over with ſedge, graſs, or the like, to hide it from the fowl; and the ſportſman is to place himſelf in ſome ſhelter of graſs, fern, or ſome ſuch thing.

DRAWING *of Gold*, or *Silver*, is the paſſing of it through a number of holes in an iron, each leſs than another, to bring it into a wire. See WIRE *Drawing*.

DRAWING *of a Bill of Exchange*, is the writing, ſigning, and giving it to the perſon, who has already paid the value or content thereof, to receive it in another place.

DRAWING, among hunters, is, when they beat the buſhes after a fox.

DRAWING *Amiſs*, is, when the hounds, or beagles, hit the ſcent of their chace the contrary way, ſo as to purſue it up the wind, when they ſhould have done it down the wind.

DRAWING *on the Slot*, is, when the hounds touch the ſcent, and draw on, till they rouſe, or put up the chace.

DRAWING is the art of repreſenting the appearances of objects by imitation; or expreſſing, by lines and ſhades, the form or appearance of any thing in nature or art: the copying of another draught, or any deſign conceived in the mind; and all this without the aſſiſtance of mathematical rules.

TREATISE ON DRAWING.

INTRODUCTION.

THERE is reaſon to believe that amongſt the firſt eſſays of human ſkill, the art of drawing had a principal place; as it is natural for the hand to form ſome kind of imitation of what the eye beholds, it may be ſuppoſed that the ſame fertile imagination which could invent inſtruments of muſic, was not deſtitute of pictureſque ideas: and that the ſame hardy ingenuity which could form into various utenſils the maſſy ore, might likewiſe poſſeſs talents ſufficient for the application of colours, which required neither toil nor ſtrength to procure, but were preſented by liberal nature upon the ſurface of the earth. If this ſuppoſition is juſt, the arts may claim an origin of remoteſt antiquity; it is certain they were employed by mankind wherever we can trace the progreſs of ſcience, and long before any period to which our reſearches can attain.

This uſeful and extenſive art, recalls to our memory things long ſince paſt, and reſcues from oblivion the deeds of our anceſtors, and revives their image in our minds, by preſerving their features for many generations; in a word, it may be ſaid to be the ſilent, but the moſt expreſſive language of nature, as it is underſtood by all nations, and conveys ideas where words prove deficient. Beſides its being an immediate introduction to painting, ſculpture, engraving, with all the train of graceful ſtudies, it is even neceſſary to form mankind for whatever ſtation deſigned; ſince nothing informs or corrects our ideas ſo effectually as a true knowledge of ſymmetry and proportion. Although this art in its extent be as ſpacious as obſervation can diſcover, or imagination conceive, yet in this Treatiſe we preſume will be found an abſtract containing examples amply ſufficient to direct a genius the leaſt apt or inquiſitive. It would be wrong on a ſudden to expect perfection in this art, yet after a few painful eſſays, a pleaſure ſucceeds in the proſpect, and grows in the practice beyond that of any other acquiſition; and ſure no one would ſpare the means where the end is ſo deſirable.

There ſeem to have been two principal reaſons for the ſuperiority of the ancient artiſts, from the remains of whoſe ſculpture we may believe the wonders recorded of their drawings. They had unqueſtionably the fineſt models, owing to a variety of cauſes; added to this, they ſtudied them with the moſt diligent aſſiduity. It may be obſerved with great propriety, that what is loſt of the beauty of the ancients, by the local and incidental circumſtances of modern manners and education, is to be traced in the remains which have been tranſmitted to us of ancient buſts, gems, and ſtatues.

The Grecian artiſts have univerſally been acknowledged to have ſurpaſſed thoſe of every other nation, but the luxury and effeminacy into which their empire dwindled, proved its deſtruction and put an end to their progreſs. They became ſubjugated to the Roman policy and power; their country was deſolated, their temples ſpoiled of their ornaments, and their capital productions were tranſported to embelliſh the porticos of Rome.

Rome was the ſeat of univerſal empire, the miſtreſs of the world; into Rome flowed all that was curious and coſtly; many generous minds were there, who prided themſelves upon their patronage of the arts, and liberally rewarded the merit of profeſſors. That the Roman artiſts attained conſiderable ſkill is granted, yet notwithſtanding their efforts to rival their maſters, the Grecian manner was always ſuperior, and the Greek productions unequalled.

It is not the lot of an art, or a ſcience, any more than that of a ſtate, or a kingdom, to continue long in glory; with great labour it reaches its zenith, and perhaps maintains a ſplendour during the lives of a few eminent men; when they are gone, it dwindles to mediocrity, and from mediocrity to neglect and oblivion.

If the morals of Greece, were luxurious, and effeminate, under what epithets ſhall we characterize the manners of the Romans? "Earthly! ſenſual! deviliſh!" Rome became the ſink into which ran the vices of every country it had ſubdued. Abandoned to impiety, ſlaves to debauchery, its citizens exulted in what ſhould have aſtoniſhed them with ſhame and horror.

We do not therefore wonder, when reading the hiſtory of thoſe times, that providence commiſſioned the barbarous nations to puniſh the licentious, the profligate Romans; our wonder rather is, that long before that period they were not involved in deſolating ruin. When the numerous herds of the ſurly north had over-run the diſtant provinces, and ravaged Italy, the artiſt hung his head in ſilent ſorrow, or burſt into lamentation at the ſavage ſcene; not ſo much for his own performances, as for the deſtruction of thoſe he had been uſed to ſurvey with wonder and delight; farewel the breathing marble! the animated picture! farewel the productions of APELLES and ZEUXIS! farewel LYSYPPUS! PRAXITELES! PHIDIAS! buried for a long, long night, beneath the ruins of the Capitol; of the Palaces; of Rome.

We have briefly hinted at the progreſs of the arts in ancient times, becauſe it does not ſo immediately concern us as what will follow upon their revival: they have accompanied learning and politeneſs: as theſe have been encouraged, the arts have have flouriſhed; when theſe have been neglected, they have drooped; when liberal ſcience and knowledge were baniſhed, they died.

It is unneceſſary to make any further eulogium on the art of drawing; the degree of eſtimation in which it is held in a country has always been reckoned a criterion by which to judge of the national taſte; and we have almoſt without exception found, that a neglect of it has been ever a mark of degeneracy or barbariſm; as the latter ages of the empire after the incurſions of the Francs and Lombards, and the modern ſtates of moſt of the Mahometan ſovereignties, may ſerve to teſtify.

The protection and cultivation which have been given to theſe purſuits in this country, within theſe few years, and eſpecially in the preſent reign, compared with that barren catalogue of artiſts and patrons, which preceded, may at leaſt evince, that we have rather advanced than receded in the knowledge and culture of thoſe arts which adorn life and poliſh taſte; and which are only to be ſucceſsfully promoted amidſt national opulence and ſplendor.

Few books have hitherto appeared in this country well ſuited to facilitate the attainment of this art; yet we are always invited to attend to ample and learned inſtructions to beginners, where the preliminary diſcourſes often puzzle and confuſe the ideas more than the examples they recommend are ever able to eradicate. But ſince example has made verbal inſtructions expected, we here ſubjoin ſuch directions as ſeem to us neceſſary to aſſiſt the ſtudent.

SECT. I.

USEFUL DIRECTIONS TO THE PRACTITIONER.

THE firſt and greateſt part of the difficulty in learners to draw, will be ſurmounted by placing before them good models for imitation, accurately delineated; the ſame pains are beſtowed on the worſt as on the beſt ſubjects. If they conſidered this, they would be curious in the choice of their examples, that they might have the leſs to unlearn. Bad habits are of all things the greateſt obſtacles to improvement, and ſcarcely to be entirely effaced by the moſt unremitting diligence. It is only by good examples of imitation that the ſtudent can form correct ideas of beauty and nature, which will always ſerve him as a ſtandard. The ſtudent's firſt uſe of them will be to attain by a deliberate ſtudy of their outlines, thoſe fixed ideas of beauty, which may always remain as ſtandards to which he ſhall refer his views of nature; to do this he muſt proceed with patience and care, "what we hope to do with eaſe (ſays an eminent modern) we muſt learn to do with diligence."

A general knowledge of the principles of muſcular anatomy; a habit of delineating the moſt uſeful inflexions of lines and contours, and a tolerable idea of the conſtituent parts of the human ſubject in ordinary nature, ſhould be the ground work for every ſcholar to build upon; nor ſhould an impatience of producing an effect from the concomitant circumſtances of light, and ſhade, divert him from a diligent ſtudy of outlines, the only ſure fundamental baſis of his future excellence. When he begins to attempt compoſition, let him accurately finiſh every part from good models; thus he will at once perfect his ſtudies as a learner, and exerciſe his imagination as an inventor. This was the conſtant practice of the beſt artiſts, and this alone will put thoſe of our days in a capacity to imitate them with ſucceſs. Let the ſcholar uſe every aid to aſſiſt his invention in compoſing, and his execution in finiſhing; the veins of a piece of marble, the accidental combinations of light and ſhadow in clouds, have given occaſion to very excellent works, when artiſts have had ſkill and genius enough to apply them with judgment.

To render landſcape perfect, the knowledge of figures becomes neceſſary; nay, it may be remarked, that the ſtudy of the human figure in its general anatomy, and in the variety of its movements, is of itſelf ſo comprehenſive a ſtudy, as not only lays a ſure ground for a juſt theoretical judgment of the art, but, in fact, includes the leſſer branches of it, as it facilitates the execution to a degree which is not to be conceived by thoſe, who from the inferior branches have applied themſelves afterwards to the higher.

The Materials uſed in Drawing, are, Charcoal, cut in long ſlips. Black lead pencils. Crayons of black, white, and red chalk. A port crayon. Indian ink. Camel's hair pencils. Fitches. Crow quill pens. A ruler and a pair of compaſſes. India rubber.

The firſt object of the ſtudent, ſhould be to ſketch his general proportions ſlightly from the ſubject he is drawing from, which he ſhould carefully ſurvey, and after, by rubbing it gently out with ſtale bread or India rubber, ſlightly and cautiouſly retouching with more correctneſs, ſtill keeping your copy ſo faint that you may with eaſe rub out and amend it. When you can find no farther diſagreement from the original in your ſketch, freſh point your pencil, and keeping a waſte paper under your hand, begin to finiſh your out-line, taking particular care to obſerve and imitate ſuch parts as appear dark, diſtinctly from thoſe which are faint or ſmaller, the ſtrong touches being what give ſpirit to the out-line, and when properly given, always denote a maſter's hand. We therefore ſhall again entreat the ſtudent to direct his greateſt attention and application to a perfect out-line, for in this principally conſiſts the Art of Drawing; this fully attained, the art will be eaſy, and the ſtudy of it become delightful. The out-line compleated,

pleated, light and ſhadow become your next concern, which is a labour ſo pleaſing, that no commendation can be given adequate to the pleaſure a real profeſſor finds in the execution of this art, or rather ſcience ſucceeding art. Beginners are apt to leave the ſtudy of out-lines too ſoon, and ſo commence painters; like thoſe who raiſe a ſtructure ere the foundation be compleated. When you ſhade with Indian ink, go exactly over your out-line with a pen dipped in common ink, with clean ſtale bread or India rubber, rub out all remains of your black lead; then mix your Indian ink, by rubbing it in an earthen ſaucer with water, till it is pretty black: then take another clean ſaucer and dip your pencil in the Indian ink, and with water mix it to the lighteſt ſhade; as it dries deepen it where neceſſary, till you come up to the ſtrength of your original. This method is moſt proper to uſe in drawing from mezzotintos or paintings.

Laſtly of Crayons, beginning with black and white: take blue or purple-colured paper, and having exactly formed your outline, begin on the ſecond degree of your ſhades, and with black chalk darken downwards; then take white French chalk, to be found at all colour-ſhops, and heighten the lighter parts to a perfect white. In this manner all paintings may be copied in their proper colours, by having different Crayons of each colour, from dark to light in due gradations. By practiſing according to the preceding rule, rolling a piece of paper to a point, and dozzeling or rubbing each colour on the paper when finiſhed, it will mellow the tints and prevent them in a great meaſure from rubbing off.

SECT. II. OUTLINES.

Drawing Eyes, Ears, Legs, Arms, Hands, Feet, &c.

As to the drawing of eyes and ears, legs and arms, the learner will have very little more to do than to copy carefully the examples given in Plate I. But the actions and poſtures of the hands are ſo many and various, that no certain rules can be given for drawing them, that will univerſally hold good. Yet as the hands and feet are difficult members to draw, it is very neceſſary, and well worth while, to beſtow ſome time and pains about them; carefully imitating their various poſtures and actions, ſo as not only to avoid all lameneſs and imperfection, but alſo to give them life and ſpirit. To arrive at this, great care, ſtudy, and practice, are requiſite; particularly in imitating the beſt prints or drawings that can be got of hands and feet, ſome good examples of which are given in Plate I. One general rule, however, may be given, which is univerſally to be obſerved in all ſubjects, and that is, not to finiſh perfectly at firſt any ſingle part, but to ſketch out faintly, and with light ſtrokes of the pencil, the ſhape and proportion of the whole hand, with the action and turn of it; and after conſidering carefully whether this firſt ſketch be perfect, and altering it wherever it is amiſs, you may then proceed to the bending of the joints, the knuckles, the veins, and other ſmall particulars, which, when the learner has got the whole ſhape and proportion of the hand or foot, will not only be more eaſily but alſo more perfectly deſigned.

Of Drawing Faces. The head is uſually divided into four equal parts. 1. A, From the crown of the head to the top of the forehead, the top line of which muſt be alloted for the hair. 2. B, From the top of the forehead to the top of the noſe between the eye brows. 3. From the eye brows to the bottom of the noſe. 4. D, From thence to the bottom of the chin. But this proportion is not conſtant; thoſe features in different men being often very different as to length and ſhape. In a well proportioned face, however, they are nearly right. To direct the learner therefore, in forming a perfect face, his firſt buſineſs is to draw a complete oval; in the middle of which, from the top to the bottom, draw a perpendicular line. Through the centre or middle of this line draw a diameter line, directly acroſs from one ſide to the other of your oval. On theſe two lines all the features of your face are to be placed as above directed, and divide your perpendicular line into four equal parts; and your diameter line, or the breadth of the face, is always ſuppoſed to be the length of five eyes; you muſt therefore divide it into five equal parts, and place the eyes upon it ſo as to leave exactly the length of one eye betwixt them. This is to be underſtood only of a full front face; for if it turn to either ſide, then the diſtances are to be leſſened on that ſide which turns from you, leſs or more in proportion to its turning. The top of the ear is to riſe parallel to the eye-brows, at the end of the diameter line; and the bottom of it muſt be equal to the bottom of the noſe. The noſtrils ought not to come out further than the corner of the eye in any face; and the middle of the mouth muſt always be placed upon the perpendicular line, as in Plate I.

We have not been ſo copious on the ſubjects of outlines, ovals, and other ſimple introductiory matters as treatiſes on drawing have generally been; becauſe we wiſh rather to refer our readers to the Plate, which will more forcibly illuſtrate thoſe principles of the art than any verbal deſcription that can poſſibly be given.

SECT. III.

PROPORTIONS AND MEASUREMENTS.

To illuſtrate theſe eſſential principles of the art, we ſhall introduce the accurate meaſurements of Monſieur Audran from the Antiques at Rome; and ſubjoin his account of them.

“ There will be, but little occaſion to enlarge upon the neceſſity of a perfect knowledge of the proportions to every perſon converſant in deſigning; it being very well known, that without obſerving them they can make nothing but monſtrous and extravagant figures.

Every one agrees to this maxim generally conſidered, but every one puts it differently in practice; and here lies the difficulty, to find certain rules for the juſtneſs and nobleneſs of the porportions; which, ſince opinions are divided, may ſtand as an infallible guide, upon whoſe judgment we may rely with certainty.

This appears at firſt very eaſy: for ſince the perfection of art conſiſts in imitating nature well, it ſeems as if we need conſult no other maſter, but only work after the life; nevertheleſs, if we examine the matter farther, we ſhall find, that very few men, or perhaps none, have all their parts in exact proportion without any defect. We muſt therefore chuſe what is beautiful in each, taking only what is called the beautiful nature. But who will ſay that he has himſelf diſcernment enough, not to be miſtaken in ſuch a choice?

Our greateſt maſters find themſelves at a loſs in this matter, and often diſagree; they form to themſelves different ideas of beauty, which they generally regulate according to their country and temper. I ſay according to their country; for ſince all men, in their air and manners, have much in them of the climate where they were born, the painters from their particular guſtos from the objects that are continually before their eyes, with which they ſo fill their imaginations, as to make all their figures conformable to them.

Hence it comes that we give a character of painters by the name of certain countries, ſaying, the piece is of the guſto of ſuch a country; and indeed this guſto is always found, more or leſs, in all the deſigners of thoſe nations.

As to our temper, that acts ſtill more powerfully in us. It is that which makes the moſt eſſential diſtinction between one man and another, and has a part in every thing we do. In this ſenſe we may ſay, that a painter paints himſelf in his works: and if we had penetration enough, we might there find his moſt prevailing inclinations. A ſecret prejudice born with us, the reaſon of which we many times do not know, is generally that which determines our choice, and cauſes us to make our figures agreeable to the air of thoſe perſons we have moſt inclination to.

There are ſome painters, in whoſe works their temper is ſo remarkable, that it is impoſſible to be miſtaken in it. We have had ſome that have been carried by their inclinations only to pleaſant ſubjects, ſuch as Diana bathing, the ſports of nymphs, and the like; others always chooſe diſagreeable ſubjects, as ſorceries, apparitions of ghoſts, and ſuch things as are frightful and terrible.

If we were to take the pains to obſerve them according to this remark, we ſhall find that their ways of living agreed with their works, and that the character of their diſpoſition might be found, not only in the choice of the ſubjects, but yet farther, in each figure in particular.

Let us add, to ſo many prejudices which we have from ourſelves, thoſe which proceed from our maſter, of whoſe manner we almoſt always retain ſomething. Upon which we may obſerve by the by, that what is called a manner, in painting, is generally a fault; it being commonly only ſome particular agreeableneſs with which we are ſo much pleaſed as to load it with exceſs; by doing which, we have paſſed the juſt point of that truth which all the world ſeeks, and to which it is ſo difficult to attain.

What can a deſigner do amidſt all theſe difficulties? I ſee nothing but the antique in which we can place an entire confidence, The ſculptors who have left us thoſe beautiful figures which remain to this day, have happily diſengaged themſelves from this perplexity. Some of theſe difficulties were not ſuch to them, and they have perfectly underſtood how to ſurmount the others.

Firſt, as to thoſe which regard the country, they worked in Greece and Italy. We know that the one abounded with beauties; and the other, being the miſtreſs of the world, every thing that was beautiful and curious came there from all parts.

As to their temper and paſſions, without doubt they were ſubject to them as well as we; indeed, a natural inſenſibility would be no very happy diſpoſition for an artiſt; and his works would hardly eſcape having a teint of this extreme coldneſs: but however, theſe great men did not ſuffer themſelves ſo to be drawn aſide by their paſſions, as not to obſerve what was to be avoided and practiſed according to the different characters of their figures; and that with ſo much exactneſs, that no one in ſo many ages has yet been able to attain that high perfection they gave their works.

We may boldly ſay, that they have in ſome ſort excelled nature; for though it be true, that really they have only imitated her; that muſt be underſtood of each part in particular, but not of the whole together; and there never was any man ſo perfect in all his parts as ſome of their figures. They have imitated the arms of one, the legs of another, collecting thus in one figure all the beauties which agreed to the ſubject they repreſented, as we ſee in the Plate, which contains the Hercules, all the ſtrokes that are marks of ſtrength; and in that of the Venus, all the delicacy and graces that can form an accompliſhed beauty. The ſculptor ſpared neither time nor care: there have been ſome that worked their whole lives in view of producing one perfect figure.

BRITISH 18 MR 63 MUSEUM

To animate them, they had three powerful motives, religion, glory, and intereſt. They conſidered it as a kind of religious worſhip to give the figures of their gods ſo much nobleneſs and beauty, as to be able to attract the love and veneration of the people. Their own glory was concerned, particular honours being beſtowed on thoſe that ſucceeded. And as to their fortune, they had no farther care to take, when they were arrived to a certain degree of merit.

Beſide theſe reaſons, which have the moſt contributed to form theſe excellent men, it is certain there are happy ages like thoſe of Alexander and Auguſtus. We live at preſent under a reign like theirs, where we ſee the arts flouriſhing in ſuch a manner, as there is reaſon to hope that they may attain at laſt to the perfection of the Greeks and Romans in their moſt finiſhed works.

However, the high eſteem we have for the ancients, though well grounded, muſt not make us blindly admire all the antique figures; there is reaſon to believe, that as there were maſters, ſo there were ſcholars too, ſome of whoſe works have been brought down to us, though they do not indeed deſerve the care that has been taken to preſerve them. Therefore among the great number there is of them, I have only choſe thoſe that have the moſt univerſal approbation, and which the greateſt deſigners look upon with admiration; and allow to be the moſt certain models to work after.

Your principal ſtudy being to be made upon theſe figures, it may be proper to mention to you, that in the beſt of them we obſerve certain things which would certainly be counted faults if they were in the works of a modern. The left leg of the Laocoon, is four minutes longer than the other; the leg of the Venus, that bends, is almoſt a part and three minutes longer than that which bears the body. The right leg of the greater of Laocoon's children, is near nine minutes longer than the left.

Nevertheleſs, I cannot forbear having a veneration even for theſe ſeeming faults; I believe the ſculptors had their reaſons for them, and that it would be raſhneſs to condemn them; how can we think that theſe great men who have been the authors of works that may be called perfect, ſhould fall into ſuch groſs miſtakes as theſe I have been ſpeaking of, if they had not been done with deſign?

Among ſeveral conſiderations with which we are not acquainted, one of them is likely to be the fore-ſhortening. I take the matter to be thus; theſe figures was made to be ſet in places where they were chiefly to be viewed from certain ſides, with heights and diſtances that might change the appearances of the object; the parts we have taken notice of being fore-ſhortened would have ſeemed defective; and it was that, I ſuppoſe, that obliged them to make them longer: whence we may draw an important conſequence, which is, that where a figure is to be viewed on all ſides, and at a diſtance, that gives us leave to examine it thoroughly, we muſt make the proportions ſuch as we find them in the antique, in thoſe parts that are ſeen without fore-ſhortening: but if the figure be placed where it can be viewed only at ſuch places and diſtances as hide ſome part from the eye; in that caſe, it would have good effect, (if it is not neceſſary) to put in practice thoſe ingenious artifices of which the ancients have made ſuch a happy uſe.

I propoſed to myſelf to make this work larger, by adding the ſame figures ſhadowed with as much guſto and correctneſs as I could, and above all, according to my meaſures; but being preſſed to give it to the public, for the benefit of the ſtudious, I thought I ought not to put it off any longer; the rather becauſe all that is neceſſary is here, and the reſt would only ſerve for entertainment. I muſt only advertiſe you, that theſe figures not being ſhadowed, and the places which would appear round, repreſenting nothing but a flat ſurface, you may chance to think them ſhort; but trouble not yourſelf with that doubt; they are in the moſt elegant proportions; if you doubt of it, draw one of them in the ſame meaſures I have marked, ſhadow it tenderly, and you will have a very light figure.

Different books have been written upon this ſubject; it ſeems to me, that ſeveral of thoſe that have treated of it, have affected to make themſelves heads of a ſect, by giving ſuch meaſures as pleaſed themſelves, without relying on any authority. I believe they are miſtaken, it is your part to judge; compare their proportions with mine, deſign the ſame figure according to the different rules, and you will ſee the effect.

Others having firſt drawn figures very regular and of a good guſto by ſight, after the antique, have afterwards meaſured the ſtatues to find the proportions, which not being done with all the exactneſs neceſſary, their writings did not agree with their figures.

I have endeavoured equally to avoid theſe two faults. I give you nothing of myſelf; every thing is taken from the antique: but I have drawn nothing upon the paper till I had firſt marked all the meaſures with the compaſſes, in order to make the out-lines fall juſt according to the numbers.

I have choſen figures of different characters, and meaſured them on ſeveral ſides, that you may find in one or in the other ſomething that may be uſeful to you. I have diſpoſed my meaſures in ſuch a manner, that you may make uſe of them whatever profeſſion you are of, where there is occaſion for drawing.

If you are a ſculptor, you will eaſily find more than another, ſuch things as may be of moſt ſervice to know; for ſince your art counterfeits nothing, and repreſents the figures with their real dimenſions, you may meaſure with the compaſſes any place about which you have any doubt.

If you are a painter, or graver, you will find likewiſe many uſeful things; becauſe, in whatever view a figure preſents itſelf, there are always many meaſurable parts. I have beſides invented a way of meaſuring different from the common; which will ſerve for the parts that go off; you will find it in the back view of the Hercules.

I confeſs, you would perplex very much the greateſt part of painters, if you were to meaſure their works with the compaſſes in all the places that can be meaſured; ſeveral ſave themſelves by the help of the graces of painting; but let us not flatter ourſelves, neither the livelineſs of the colouring, nor the richneſs of the diſpoſitions, nor the ſtrongeſt expreſſion, will make a beautiful whole, except they are ſuſtained by the correctneſs of the drawing. However, let not that diſcourage you; for though few pictures will bear ſuch an examination, yet we may uſe all the ſeverity of the compaſſes to the works of Raphael, Hannabel Carracci, Pouſſin, and ſome of our moſt famous maſters; we even know ſome at this day with whom we may uſe this way; their modeſty forbids my naming them; their works make them ſufficiently known; examine them well; you will find painters whoſe pictures are juſt in all their proportions by outlines both correct and graceful.

When I give ſuch great commendations to thoſe painters whoſe works may be meaſured, I do not mean to make you ſpend too much time in meaſuring your figures with the compaſſes, which would certainly hinder your progreſs in drawing; but you may uſe the compaſſes and my meaſures, whenever you have any difficulty about the proportions; then having informed your judgment ſeveral times, it will become natural to you, and you will get a habit of obſerving them regularly without the compaſſes.

In the laſt place, do not take it ill that I ſpeak well of my own work, the principal honour is not for me, it is the antique I commend. The antique preſents me admirable works; I make them my principal ſtudy, I am obliged to it for the little I know; I collect the meaſures that I may the better examine the beauties, and now offer them to you, hoping you will find as much benefit by them."

Directions for the Meaſurements.

"IN order to underſtand theſe meaſures and their uſe, it will be neceſſary to know, that it is the manner of good painters and ſculptors, to make their figures a little bending, to give them an appearance of freedom and gracefulneſs; and almoſt all the antique ſtatues are in this manner, more or leſs, as the different ſubjects require. The places where this bending is made, are, the knees, the loins, and the head; which however in ſome figures is but very little, as in the Apollo which is almoſt upright; but in others, as the Antinous, amounts to about one part ten minutes. Therefore when we ſay that a figure has ſo much in height, it is not meant, that the ſtatue meaſured from the crown of the head, to the ſole of the foot, in the attitude it is in, has ſo much height as we give it, but it is to be underſtood, ſuppoſing the figure to ſtand upright, and equally poized on both feet, that then it would have the height we ſet down.

"This being ſuppoſed, I have meaſured theſe figures according to the height they would have if they ſtood upright; I have marked, in ſome places where the parts appear leſs than they are, and have taken my principal meaſures from thoſe parts which appear in their proper bigneſs.

"The meaſures of the whole are regulated by thoſe of the head according to the uſual method. The head is divided into fonr parts, one of which reaches from the lower part of the chin to the lower part of the noſe; another, from the lower to the upper part of the noſe between the eye-brows: a third, from between the eye-brows to the hairs upon the forehead; and a fourth, from thence to the top of the head, which is plainly illuſtrated in the head of Hercules. Each part is divided into twelve minutes, and the minutes into halfs, thirds, and quarters. For example, P. ſignifies a part, M. a minute, M$\frac{1}{2}$, half a minute, M$\frac{1}{3}$, one third of a minute, M$\frac{1}{4}$, a quarter of a minute. It is to he obſerved, that when I mark half a minute it is thus, M$\frac{1}{2}$, and when a minute and half, thus, 1 M$\frac{1}{2}$."

SECT. IV.

THE MOTION OF THE MEMBERS.

We ſhall now proceed to deſcribe that eſſential part of drawing wherein ſo much beauty conſiſts, viz. the motions of the members in the human figure: and further to explain this important particular, we ſhall devote a Plate ſolely to the ſubject, which will ſerve not only to aſſiſt the ſtudent in the earlier ſtages of the art, but be uſeful to ſuch as have made a progreſs in it, in furniſhing them with all the paſſions and attitudes that are neceſſary to form a compoſition to illuſtrate any paſſage of hiſtory. This part of drawing depends chiefly upon properly contraſting or oppoſing the different members of the body, and their reſpective lights and ſhades. This is chiefly effected by a graceful turn or ſway of the whole form, e. gr. when the face is placed in front, the body ſhould turn a little aſide, with the legs ſtill fronting the ſpectator, (See *Fig*. I.) in the Plate illuſtrative of this ſubject; in the ſecond place, there muſt be a contraſt in the inclining of the figure, e. gr. if one ſhoulder riſe, the other ſhould ſink; the hips, knees, and feet, the ſame as in the above figure, where the right ſhoulder riſes, the right hip falls, the right knee or foot riſing again, and falling on the oppoſite ſide of the body.

A third obſervation is, that when the right arm and left leg advance, the left arm and right leg, ſhould fall back. This motion is doubled when the right ſhoulder is ſeen fronting; for then, the head and lower part of the body muſt be the ſame, as *Fig*. I. demonſtrates; and when the breaſt riſes the head ought to ſink, and vice verſa. Care muſt be taken that the hand and arm be not on a line, but that each contraſt the other by the oppoſing turn.

The croſs line of the face is never parallel with that of the body, either fronting or in profile, nor the upper part of the body with the lower. To the proper regulation of theſe attitudes or motions of the body, it owes its beauty with reſpect to form. As for the motions, the three following are the principal. 1. That of the head. 2. That of the hands and feet. Laſtly, that of the body. Thoſe of the head are four, forward, backward, and on each ſide; thoſe of the hands and feet are the ſame. The arms and legs have but one motion; one on the elbow, the other at the knee, the arm bending and the leg drawing back. The motions of the body are three, forwards, backwards, and on one ſide.

Beſides theſe, there are four other ſorts of motions proceeding from the ſame members which we may ſtile the ſimple, the active, the reſtleſs, and the violent. 1. The ſimple is when the members move naturally, as in walking, eating, or drinking. 2. The active conſiſts in carrying, pulling, thruſting, preſſing, climbing, and the like. 3. The reſtleſs ariſes from diſquiets of the mind where the paſſions are ſhown by the geſtures of the body, as in love, hatred, anger, ſorrow, joy, ſpite, ſcorn, and ſuch like; the effect produced is chiefly viſible in the leſſer members, as the eyes, noſe, mouth, and finger. The violent proceeds from the effect produced by fright, fear, deſpair, rage, which occaſion a ſhrinking, a ſtretching, and violent action of the members. A perſon may be ſometimes affrighted by any incident without ſhewing it in the face. We may be in love, and it ſhall not appear in our countenance, but our deſign is to expreſs the paſſions by the motions of the members in the body, as well as thoſe of the face, the latter of which we ſhall illuſtrate in the following part, by giving Mr. Le Brun's ideas on the ſubject. In ſhort, a perfect figure can only be deſigned by a ſtrict attention to the effect produced by the different paſſions, upon the ſeveral members of the body, and contraſting their appearances with judgment.

Motions of the Members, as actuated by the different Paſſions.

It is not always the language that produces the greateſt effect on the party deſigned to be moved; there is often more eloquence in a flood of tears, than in the beſt ſpoken oration, and in a ſilent attitude, than in a tempeſt of words. Indeed it has frequently been ſaid, it was not ſo much the words as the manner of ſpeaking that gave offence, or ſatisfaction; which "manner of ſpeaking" is part of expreſſion. There is a difference between geſticulation and expreſſion, the former being an acquired and conſtant habit, the latter the offspring of mental ſenſibility. All the members of the perſon contribute to expreſſion; an elevation of the head expreſſes haughtineſs, diſdain, contempt; a depreſſion, modeſty, humility, reſpect; when borne evenly, it indicates firmneſs; when ſinking on one ſide, dejection. The hands are very conſiderable agents in this buſineſs: by them we applaud, we requeſt, we refuſe, we command. In requeſt we hold our hands level, the palm upward, as if to receive what we deſire; in refuſing, we turn the palm of the hand downward, thereby rendering it impoſſible the object intended ſhould be put in it; in commanding, we point to what we order to be done, and ſometimes the finger held up is a ſufficient authoritative. The feet as the means of advancing and retreating, chiefly, if not altogether, in thoſe motions contribute to expreſſion. It is ſeldom the feet contradict the motions of the hands, but ſometimes they are ready for eſcape from dangers wherein the hands will venture. We ſhall proceed to notice the paſſions in the following order: ADMIRATION, which produces but little change in the features of the countenance, has ſcarce greater effect on the figure: it may be repreſented by a perſon ſtanding erect, his hands open and lifted up, his arms approaching his body; ſtanding pretty firmly on his feet. In ESTEEM, the body will be rather bent, the ſhoulders rather elevated though but little; the arms folded and cloſe to the body; the hands opened, and not very diſtant from each other; the knees bent. VENERATION encreaſes the flexure of the body, and of the knees; the hands and arms almoſt unite; all parts of the body mark profound reſpect. When connected with objects of faith, VENERATION augments the ſtrength of the foregoing motions; croſſes the hands on the breaſt, lowers the head, and bends the body to proſtration. RAPTURE, or extacy, may be expreſſed by the body thrown backwards, the arms elevated, the hands open; the whole action, joyful, animated, tranſported. The effect of SCORN is to draw back the body, to extend the arms, as repulſing the object of averſion; the legs ſtiff. HORROR excites violent movements; the body greatly withdrawn from the object which cauſes the paſſion, the hands will be quite open, the fingers ſpread, the arm kept tight to the body; the legs endeavouring to eſcape. AFFRIGHT has very vigorous expreſſions, the arms thrown for ward ſeem to ſtiffen; the legs fly with the utmoſt rapidity; and every part of the body recoils from its dreaded adverſary. LOVE creates no great emotion in the figure; the preſence of its object animates the motion, but not very ſtrongly, not after any fixed manner in modeſt affection. DESIRE extends the arms towards its object, and inclines the whole body on that ſide: all the parts appear agitated and reſtleſs. HOPE excites motions contradictory and fluctuating, wavering between doubt and expectation. JOY is a firſt ſtep to rapture; its motions are more or leſs moderate. FEAR has many motions in common with affright, when it ariſes from a dread of loſing ſomewhat we value, or when we expect a calamity to befall us. This paſſion ſhrugs the ſhoulders, keeps tight the arms and hands to the body, the other parts are bent, and as if it were collected together and ſhivering. JEALOUSY has an invincible curioſity to watch its object, the head and upper part of the body will produce themſelves, in hopes of eſcaping notice by means of the feet, which ſtand ready for retreat. The agitations of ANGER are exceſſive and outrageous, the muſcles ſwelled, highly inflated and diſtinct, the veins prominent; and the whole figure in fury. ANGER would generally deſtroy its object if poſſible, and may be repreſented as ſo employed. What ſhall we ſay of DESPAIR? It is a madneſs, a poſſeſſion, an unutterable ſuffering, a principal ingredient of hell: in its motions cloſely allied to anger.

We have attended to each paſſion apart, that we might attain a clearer, and more forcible conception of its motions; it is however very ſeldom that any paſſion is free from ſome mixture with others; their combinations may eaſily be gathered from what we ſhall ſuggeſt on this ſubject in relation to the countenance.

SECT. V. LIGHT AND SHADE.

Lights and ſhades are important objects; for without a tolerable knowledge of them, it is impoſſible to produce a good Drawing; we ſhall therefore make ſome obſervations ou the ſubject.

After the learner has made himſelf in ſome meaſure perfect in drawing human figures, his next endeavour muſt be to ſhade them properly. It is this which gives an appearance of ſubſtance, ſhape, diſtance, and diſtinction, to whatever bodies he endeavours to repreſent, whether animate or inanimate. The beſt rule for doing this is, to conſider from what point, and in what direction, the light falls upon the objects which he is delineating, and to let all his lights and ſhades be placed according to that direction throughout the whole work.

That part of the object, whether in naked figures, drapery, or buildings, that ſtands fartheſt out, muſt be made the lighteſt, becauſe it comes neareſt to the light; and the light looſeth ſo much of its brightneſs, by how much any part of the body bends inward, becauſe thoſe parts that ſtick out hinder the luſtre and full brightneſs of the light from ſtriking on thoſe parts that fall in. Titian uſed to ſay, that he knew no better rule for the diſtribution of lights and ſhadows, than his obſervations drawn from a bunch of grapes. Sattins and ſilks, and all other ſhining ſtuffs, have certain glancing reflections, exceeding bright, where the light falls ſtrongeſt. The like is ſeen in armour, braſs pots, or any other glittering metal, where you ſee a ſudden brightneſs in the middle or centre of the light, which diſcovers the ſhining nature of ſuch things. Obſerve alſo, that a ſtrong light requires a ſtrong ſhade, a fainter light a fainter ſhade; and that an equal balance be preſerved throughout the piece between the lights and ſhades. Thoſe parts which muſt appear round, require but one ſtroke in ſhading, and that ſometimes but very faint; ſuch parts as ſhould appear ſteep or hollow, require two ſtrokes acroſs each other, or ſometimes three, which is ſufficient for the deepeſt ſhade. Care muſt be alſo taken to make the outlines faint and ſmall in ſuch parts as receive the light; but where the ſhades fall, the outline muſt be ſtrong and bold. The learner muſt begin his ſhadings from the top, and proceed downward, and uſe his utmoſt endeavours both by practice and obſervation to learn how to vary the ſhadings properly; for in this conſiſts a great deal of the beauty and elegance of drawing. Another thing to be obſerved is, that as the human ſight is weakened by diſtances, ſo objects muſt ſeem more or leſs confuſed or clear according to the places they hold in the piece: thoſe that are very diſtant; weak, faint, and confuſed: thoſe that are near and on the foremoſt ground; clear, ſtrong and accurately finiſhed.

When you round the parts of an object, it requires the niceſt touch of the pencil to draw the extremities ſo, as that in turning they ſhall looſe themſelves inſenſibly and confuſedly, without too ſudden a tranſition of the light into the ſhadows, or the ſhadows into the light; but let the one paſs into the other as it were reciprocally, and imperceptibly, that is by degrees of light into ſhadow, and ſhadow into light.

It ſhould be farther obſerved in regard to lights and ſhades, that it is not enough that remote objects be coloured in a more faint and languid manner, but the more or leſs diſtant they are, the parts ſhould be more or leſs made out; the eye cannot minutely diſcriminate an object which is at a diſtance from it. We can ſee human figures at a ſtreet's length, but cannot diſcern the features of their faces or the plaits in their cloaths; ſo the innumerable leaves of a diſtant grove appear to the ſight but as one maſs.

In the repreſentation of bodies you muſt always give them ſuch lights as are moſt proper and convenient for their ſuppoſed ſituations. Suppoſe the objects before you to be in fields or open air, and the ſun obſcured with clouds, your buſineſs is to introduce an univerſal light, though not vivid or ſtrong, your ſhades too muſt be faint. But when the ſun appears in all its glory, you lights muſt then be very ſtrong and bold, and the ſhadows exceeding dark.

Though the beauty of a figure conſiſts in a good proportion and diſpoſition of its parts with reſpect to action and paſſion; yet it cannot be ſaid to be abſolutely perfect till further improved by beautiful lights and ſhades; for it is to be obſerved that too faint lights render objects imperfect, and produce diſagreeable effects. This will be the caſe, when through want of attending to the effect of objects, an improper light is introduced as when a violent paſſion is repreſented in a feeble light, the effect muſt certainly be loſt; on the other hand, when tender and pleaſing objects, are repreſented in too ſtrong and broad a light, and the ſhade too ſharp, the beauty, grace and ſtillneſs of the compoſition is materially injured.

Some artiſts injudiciouſly contend, that it is impoſſible for different lights in the ſame piece to look well; and to ſupport this argument they alledge that if the principle were juſtifiable, Raphael, Caracci, Titian, Pouſſin, and other great maſters, would have not rejected, but approved of it. Notwithſtanding we acknowledge the great merit of theſe ancient maſters, we cannot but concur in the opinion and practice of the moſt eminent artiſts of the preſent day, whoſe productions evidently point out the advantage of many lights; and when they are judiciouſly managed, it is demonſtratively evident, that they give the piece a diverſifying elegance. But it ſhould be obſerved, that thoſe who are not fully acquainted with the effects of lights and ſhades, ſhould be cautious how they introduce them; for when they are too profuſe, they exhibit a fond conceit without a baſis.

Objects in a common light have no broad ſharp lights, and their ſhades are uncertain; becauſe the objects being lighted on all ſides, without miſt or fog, appear better relieved than in ſunſhine. The common light alſo has not that force and oppoſition, which the ſun light has; but its harmony is more agreeable, becauſe it has not that ſudden contraſt of light and ſhade, and therefore is better ſuited to portraits, and ſubjects where the landſcape is made ſubordinate to the drawing; but where it is the principal object, a preference is to be given to a ſun light, as it gives ſpirit and nature to the performance.

Hence it becomes highly important, before a compoſition is begun, to conſider alternately the nature and effects of the ſubject. For inſtance, whether it be the murder of Julius Cæſar in full ſenate, or the death of Cato, or the nuptials of Stratonica with Antiochus; or the reception of Queen Sheba, with her train of female attendants by Solomon; becauſe thoſe different ſubjects require the repreſentation of different paſſions. In the former are diſplayed conſternation, fright, and confuſion in the extreme; nay all is in motion. In the latter, nothing is prevalent, but captivating beauty, eaſy carriage, winning modeſty, with all their alluring charms. It cannot ſurely admit of a doubt, that the two former ſubjects ſhould be repreſented in ſtrong and ſharp lights, and the two latter in ſoft and delicate. The effect depends on the nature and qualities of theſe lights; ſome conveying ideas of ſtrength and ſharpneſs, others of ſweetneſs, ſoftneſs, and pleaſure. But the reverſe of a due repreſentation deſtroys the ſubject, for in that caſe, the two former examples might be termed *a graceful confuſion*, and the two latter, a *ſevere amour*. It may be concluded upon the whole, that a figure well proportioned and diſpoſed, having a graceful motion and ſway, and lights and ſhades agreeable to its outline, may be called a perfect figure.

It is a great fault in a certain painter well known amongſt the artiſts, and whoſe ſingularity has often been remarked, in uttering when inſtructing his pupils, the words Broad! Broad! in a tone ſo low that no ſtranger might hear it, as if it were a ſecret unknown to the very art. This brings to recollection an anecdote of Philemon the painter, who was ſo prepoſſeſſed in favour of broad lights, that in all his paintings, he repreſented the objects as if the ſun was ſhining on them at noon-day. This prepoſſeſſion he evinced in exerting his utmoſt ability, to repreſent Jupiter with Alcmena, where, though they both are preparing for repoſe, the ſun ſhines quite bright into the room. Alas! Jupiter what indignity is offered thee! Dares Phœbus, contrary to your expreſs command, peep through the windows, though you charged him to hide for three days and three nights? But what avails that, (ſays the painter) the painting muſt be broad, and the ſun-ſhine muſt be there were it midnight. Had he made a moon-light, it would have fitted that ſeaſon.

SECT. VI. OF DRAPERY.

In the art of cloathing the figures, or caſting the drapery properly and elegantly upon them, many things are to be obſerved. 1. The eye muſt never be in doubt of its object; but the ſhape and proportion of the part or limb, which the drapery is ſuppoſed to cover, muſt appear; at leaſt ſo far as art and probability will permit: and this is ſo material a conſideration, that many artiſts draw firſt the naked figure, and afterwards put the draperies upon it. 2. The drapery muſt not ſit too cloſe to the parts of the body: but let it ſeem to flow round, and as it were to embrace them; yet ſo as that the figure may be eaſy, and have a free motion. 3. The draperies which cover thoſe parts that are expoſed to great light, muſt not be ſo deeply ſhaded as to ſeem to pierce them; nor ſhould thoſe members be croſſed by folds that are too ſtrong, leſt by the too great darkneſs of their ſhades the members look as if they were broken. 4. The great folds muſt be drawn firſt, and then ſtroked into leſſer ones: and great care muſt be taken that they do not croſs one another improperly. 5. Folds in general ſhould be large, and as few as poſſible. However, they muſt be greater or leſs according to the quantity and quality of the ſtuffs of which the drapery is ſuppoſed to be made. The quality of the perſons is alſo to be conſidered in the drapery. If they are magiſtrates, their draperies ought to be large and ample; if country clowns or ſlaves, they ought to be coarſe and ſhort; if ladies or nymphs, light and ſoft. 6. Suit the garments to the body, and make them bend with it, according as it ſtands in or out, ſtrait or crooked; or as it bends one way or another; and the cloſer the garment ſits to the body, the narrower and ſmaller muſt be the folds. 7. Folds well imagined give much ſpirit to any kind of action; becauſe their motion implies a motion in the acting member, which ſeems to draw them forcibly, and makes them more or leſs ſtirring as the action is more or leſs violent. 8. An artful complication of folds in a circular manner greatly helps the effects of fore-ſhortenings. 9. The ſhades in ſilk and fine linen are very thick and ſmall, requiring little folds and a light ſhadow. 10. Obſerve the motion of the air or wind, in order to draw the looſe apparel all flying one way: and draw that part of the garment that adheres cloſeſt to the body, before you draw the looſer part that flies off from it; leſt, by drawing the looſe part of the garment firſt, you ſhould miſtake the poſition of the figure, and place it awry. 11. Rich ornaments, when judiciouſly and ſparingly uſed, may ſometimes contribute to the beauty of draperies. But ſuch ornaments are far below the dignity of angels or heavenly figures; the grandeur of whoſe draperies ought rather to conſiſt in the boldneſs and nobleneſs of the folds, than in the quality of the ſtuff, or the glitter of ornaments. 12. Light and flying draperies are proper only to figures in great motion, or in the wind: but when in a calm place, and free from violent action, their draperies ſhould be large and flowing; that, by their contraſt and the fall of the folds, they may appear with grace and dignity.

SECT. VII. ON THE PASSIONS.

The paſſions, ſays M. Le Brun, are motions of the ſoul, either upon her purſuing what ſhe judges to be for her good, or ſhunning what ſhe thinks hurtful to her; and commonly, whatever cauſes emotion of paſſion in the ſoul, creates alſo ſome action in the body. It is therefore neceſſary for a pupil to know which are the different actions in the body that expreſs the ſeveral paſſions of the ſoul, and how to delineate them.

M. Le Brun has been extremely happy in expreſſing many of the paſſions, the pupil cannot ſtudy any thing better than the examples which he has left us of them. However, as M. De Piles juſtly obſerves, it is abſurd as well as impoſſible to pretend to give ſuch particular demonſtrations of them as to fix their expreſſion to certain ſtrokes, which the artiſt ſhould be obliged to make uſe of as eſſential and invariable rules. This, ſays he, would be depriving the art of that excellent variety of expreſſion which has no other principle than diverſity of imagination, the number of which is infinite. The ſame paſſion may be finely expreſſed ſeveral ways, each yielding more or leſs pleaſure in proportion to the artiſt's underſtanding, and the ſpectator's diſcernment. Tho' every part of the face contributes towards expreſſing the ſentiments of the heart, yet the eye-brow, according to M. Le Brun, is the principal ſeat of expreſſion, and where the paſſions beſt make themſelves known. It is certain, ſays he, that the pupil of the eye, by its fire and motion, very well ſhews the agitation of the ſoul, but then it does not expreſs the kind or nature of ſuch an agitation; whereas the motion of the eye-brow differs according as the paſſions change their nature. To expreſs a ſimple paſſion, the motion is ſimple: to expreſs a mixed paſſion, the motion is compound: if the paſſion be gentle, the motion is gentle; and if it be violent, the motion is ſo too. We may obſerve farther, ſays he, that there are two kinds of elevation in the eye-brows. One, in which the eye-brows riſe up in the middle; this elevation expreſſes agreeable ſenſations, and it is to be obſerved that then the mouth riſes at the corners: another, in which the eye-brows riſe up at the ends, and fall in the middle; this motion denotes bodily pain, and then the mouth falls at the corners. In laughter, all the parts agree, for the eye-brows, which fall toward the middle of the forehead, make the noſe, the mouth, and the eyes, follow the ſame motion. In weeping, the motions are compound and contrary; for the eye-brows fall toward the noſe and over the eyes, and the mouth riſes that way. It is to be obſerved alſo, that the mouth is the part of the face which more particularly expreſſes the emotions of the heart: for when the heart complains, the mouth falls at the corners; when it is at eaſe, the corners of the mouth are elevated: and when it has an averſion, the mouth ſhoots forward, and riſes in the middle.

“ The head, ſays M. De Piles, contributes more to the expreſſion of the paſſions than all the other parts of the body put together. Thoſe ſeparately can only ſhew ſome few paſſions, but the head expreſſes them all. Some, however, are more peculiarly expreſſed by it than others; as humility, by hanging it down; arrogance, by lifting it up; languiſhment, by inclining it on one ſide; and obſtinacy, when with a ſtiff and reſolute air it ſtands upright, fixed, and ſtiff between the two ſhoulders. The head alſo beſt ſhews our ſupplications, threats, mildneſs, pride, love, hatred, joy, and grief. The whole face, and every feature, contributes ſomething, eſpecially the eyes; which, as Cicero ſays, are the *windows of the ſoul*. The paſſions they more particularly diſcover are, pleaſure, languiſhing, ſcorn, ſeverity, mildneſs, admiration, and anger; to which one might add joy and grief, if they did not proceed more particularly from the eye-brows and mouth; but when thoſe two paſſions fall in alſo with the language of the eyes, the harmony will be wonderful. But though the paſſions of the ſoul are moſt viſible in the lines and features of the face, they often require the aſſiſtance alſo of the other parts of the body. Without the hands, for inſtance, all action is weak and imperfect; their motions, which are almoſt infinite, create numberleſs expreſſions: it is by them that we *deſire*, *hope*, *promiſe*, *call*, *ſend back*; they are the inſtruments of *threatening*, *prayer*, *horror*, and *praiſe*; by them we *approve*, *condemn*, *refuſe*, *admit*, *fear*, *aſk*; expreſs our *joy* and *grief*, our *doubts*, *regrets*, *pain*, and *admiration*. In a word, it may be ſaid, as they are the language of the dumb, that they contribute not a little to ſpeak a language common to all nations, which is the language of drawing.

When the heart is dejected, ſo are all parts of the face; but when the heart is enflamed and hardened by ſome paſſion, the parts of the face follow a ſimilar movement, particularly the mouth, which proves that this part exhibits more eſpecially the ſenſations of the heart. For we muſt obſerve, that when the heart ſuffers, the corners of the mouth ſink; when it is ſatisfied, they riſe: when the heart has averſion to any object, the mouth expreſſes that averſion by riſing in the middle and pouting. Thus we ſee that all parts of the face contribute to expreſſion, according to the nature and force of the ſentiment which impels them.

SECT. VIII.

ON DRAWING LANDSCAPES, BUILDINGS, &c.

To be able, on the ſpot, to take the ſketch of a building, of a beautiful proſpect; of any curious production of art, or uncommon appearance in nature; is not only a very deſirable accompliſhment, but a very agreeable amuſement. Rocks, mountains, fields, woods, rivers, cataracts, cities, towns, caſtles, houſes, fortifications, ruins, or whatever elſe may preſent itſelf to view on our journeys or travels in our own or foreign countries, may be thus brought home, and preſerved for our future uſe either in buſineſs or converſation. On this part, therefore, more than ordinary pains ſhould be beſtowed.

All drawings conſiſt in nicely meaſuring the diſtances of each part of the piece by the eye. In order to facilitate this, let the pupil imagine in his own mind, that the piece he copies is divided into ſquares. For example: ſuppoſe or imagine a perpendicular and a horizontal line croſſing each other in the centre of the picture you are drawing from; then ſuppoſe alſo two ſuch lines croſſing your own copy. Obſerve in the original, what parts of the deſign thoſe lines interſect, and let them fall on the ſame parts of the ſuppoſed lines in the copy: we ſay, the ſuppoſed lines; becauſe though engravers, and others who copy with great exactneſs, divide both the copy and original into many ſquares, yet this is a method not to be recommended, as it will be apt to deceive the learner, who will fancy himſelf a tolerable proficient, till he comes to draw after nature, where theſe helps are not to be had, when he will find himſelf miſerably defective, and utterly at a loſs.

If he is to draw a landſcape from nature, let him take his ſtation on a riſing ground, where he will have a large horizon: and mark his tablet into three diviſions, downwards from the top to the bottom; and divide in his own mind the landſcape he is to take, into three diviſions alſo. Then let him turn his face directly oppoſite to the midſt of the horizon, keeping his body fixed, and draw what is directly before his eyes upon the middle diviſion of the tablet; then turn his head, but not his body, to the left hand, and delineate what he views there, joining it properly to what he had done before; and, laſtly, do the ſame by what is to be ſeen upon his right hand, laying down every thing exactly, both with reſpect to diſtance and proportion

In drawing landſcapes, the beſt way is to get upon a riſing ground, make the neareſt objects in the piece the higheſt, and thoſe that are farther off to ſhoot away lower and lower till they come almoſt level with the line of the horizon, leſſening every thing proportionably to its diſtance, and obſerving alſo to make the objects fainter and leſs diſtinct the farther they are removed from the eye. He muſt make all his lights and ſhades fall one way; and let every thing have its proper motion; always remembering, that whatever motions are cauſed by the wind, muſt be made all to move the ſame way.

In drawing of landſcapes, many draftſmen find the leaſage of trees an arduous taſk. Moſt of them copy after the manner of the artiſt, who particularly pleaſes them. By this means their leaſage generally becomes ſet and ſtiff, from the difficulty of copying after nature. This manner may be admitted in ſuch as are commencing the art, but thoſe who have made a proficiency in it ſhould follow nature, as it will inſtruct them better in their growth and ſhape. To gain any eminence in the ſtudy, ſtrict obſervation ſhould be made of the ſeveral ſorts of leaſage ſeen at a diſtance, whether they are cloſe and maſſy, or thin leaved and branched; or whether they hang in cluſters, or uniformly on their boughs: attend nicely to the difference of their colours in their ſeveral kinds, as well while growing, as in perfection and decay.

Finally, it muſt be obſerved, that in order to attain any conſiderable proficiency in drawing, a knowledge of Perspective is abſolutely neceſſary; ſee that article.

CONCLUSIVE REMARKS.

Many who have not attained to a knowledge of the truth of nature in the art we have been deſcribing, impute their deficiency to want of talent and ability, when upon due reflection it will be found to ariſe from an inert diſpoſition, which prevents them from purſuing ſuch means as would render them flouriſhing artiſts. From a falſe perſuaſion of its unſurmountable difficulties, they are induced to abandon the cultivation of the art; though by a ſedulous attention to the ſtudy and practice of it, there is every ground to conclude they would make a proficiency.

It may be alledged by thoſe who have practiſed from their early years, and ſtill continue the purſuit, and call themſelves artiſts, yet have made no conſiderable progreſs, that our obſervations are not founded upon truth; but ſuch an inference is erroneous, and the reſult of an obſtinate adherence to one ſtated mode, inſtead of inveſtigating knowledge and tracing nature up to her nobleſt ſprings.

To further improvement, and acquire proficiency, it ſhould be the fixed reſolution of an artiſt, to ſelect every production of merit, to devote the whole of his leiſure time to attendance on ſales, exhibitions and collections of pictures. He ſhould diligently explore the beauties and mark the defects of the ſeveral pieces, in order to retain and copy their excellencies and reject their imperfections.

By theſe means he will gradually improve in judgment and practice, and every piece he produces will ſurpaſs the foregoing; for a laudable zeal to excel in a purſuit, rarely fails of effecting the deſign; we therefore venture to offer it as our opinion, that to a neglect of the means we have propoſed, may in general be imputed the obſtacles which impede a progreſs in the art.

With reſpect to engravers in particular we are ſorry to remark, that through neglect of the remarks we have made, many of the preſent time, whoſe names we forbear to mention, diſplay in their latter productions, no more traits of merit, than in thoſe they exhibited twenty years paſt. From their want of obſervation, and conſequent inability, their pupils through impulſe of genius have been reduced to a neceſſity of rejecting their falſe principles, and making nature and good originals their models to copy after, rejecting the guidance and inſtruction of their incompetent maſters. To confirm theſe remarks, we need only to advert to the productions of young artiſts, as Heath, Smith, Neagle, Bromley, Grainger, &c. and compare them with thoſe of the engravers, to whom they were pupils. What a difference muſt we diſcover! What infinite ſatisfaction muſt it afford thoſe who are anxious for the advancement of the art in this country, to find ſo many young profeſſors in ſo early a ſtage diſplay ſuch wonderful abilities!

Though we have at this time in the kingdom, ſuch a numerous catalogue of excellent engravers, and a few years ago the names of Grignion, Scotin, Vander-Gucht, and Ravenet, only were regarded, ſuch is the improvement of the public taſte, and ſuch their avidity for capital productions, that if we had double the number, they would meet with ample encouragement.

This may be aſcribed to that accurate judgment of the merits of engravings, that has prevailed amongſt people in general, ſince Woolett's engraving of the death of General Wolfe. The proof impreſſions of that print having been ſold at the enormous price of fifteen or twenty pounds, raiſed the ſurprize and aſtoniſhment of all who knew its eſtimate, but were unacquainted with its merits. Hence they were induced to examine the particulars which conſtituted ſuch exquiſite merit, and from minute inſpection and diligent enquiry, they formed competent ideas which became the ſtandard of their judgment, with reſpect to other productions.

In forming this Treatiſe, I have deviated from the plan generally adopted, in avoiding prolixity on the leſs important points, in order to afford ſcope for ſuch as are eſſential. I do not offer it as a production wholly of my own, having received from the publiſher many hints of a highly important nature, as his long practice, and the proficiency he has made in the art, under the inſtruction of Mr. Green, Drawing Maſter to Chriſt's Hoſpital, has rendered him competent to ſelect many valuable materials for the compoſition. To his judgment it is but juſtice in me to aſcribe the well choſen Subjects and well executed Prints, which embelliſh his works in general. The precepts contained in this Treatiſe are not propoſed as laws but examples, as the reſult of practice and obſervations; and if they tend to the advancement of the ſtudent in the art, I ſhall be highly delighted to think my endeavours have been uſeful.

No. 37, Tottenham Court Road. *GEORGE GRAHAM.*

DRAY, a kind of cart uſed by brewers, for carrying barrels of beer, or ale; alſo a ſledge drawn without wheels.

DRAY, among ſportſmen, denotes ſquirrel-neſts, built in the tops of trees.

Dissertation upon Dreams.

DREAMS; thoſe fancies or imaginations which occur to the minds of people when aſleep.

The ſubject of dreaming hath been inveſtigated by ſeveral philoſophers, but hitherto with very little ſucceſs. Wolfius ſuppoſes that dreams take their riſe entirely from the ſenſations; and that no dream ariſes in the human mind without a previous ſenſation, though perhaps ſuch a ſlight one that it cannot eaſily be traced. This hypotheſis is expreſsly adopted by Mr. Formey, in an eſſay on dreaming, in the Memoirs of the Academy of Sciences at Berlin. Mr. Baxter, in his treatiſe of the Immateriality of the human Soul, attributes dreams to the action of ſome immaterial beings upon our ſouls. Laſtly, ſome modern phyſiologiſts reckon dreaming to be a ſpecies of delirium. Their account of the matter is as follows. The brain and nervous ſyſtem, which are the only organs of ſenſation, are generally in two ſtates, exeeedingly different from one another, which may be expreſſed by the words excitement and collapſe. The firſt of theſe denotes that ſtate in which the nervous ſyſtem is eaſily made ſenſible of the impreſſions of external objects, and then we are ſaid to be awake. The ſecond is, when external objects do not eaſily make theſe impreſſions: and of this ſtate there are various degrees; drowſineſs, ſleep, fainting, and death. Theſe do not indeed proceed in the order in which we have placed them. Sleep is of a quite different nature from fainting, or from that ſtupor and inſenſibility produced by a compreſſion of the brain. But, whatever be the nature of ſleep, it is certain that this ſtate is attended with what we call a collapſe of the brain; as external objects do not make the ſame impreſſions on the organs of ſenſe when people are aſleep, that they do when awake. Between the two ſtarts of ſleeping and waking, a ſtate of delirium always occurs; and this is moſt probably occaſioned by the excitement of one part of the brain, and the collapſe of another. That one part of the brain is capable of being excited, while the other ſuffers a collapſe, will be evident from conſidering what happens when we are juſt falling aſleep. Every one muſt be ſenſible, that at that time we do not loſe our ſenſes all at once. The hearing will continue after the ſight is loſt; and, even while we are yet conſcious of the place we are in, falſe imaginations of a nature ſimilar to that of dreaming will occur to our minds. But when the brain is perfectly collapſed, ſenſation or imagination of every kind totally vaniſhes, and we are altogether inconſcious of exiſtence.

On a ſubject ſo obſcure, and ſo much out of the reach of inveſtigation, as that of dreaming, it is difficult to advance any thing ſatiſfactory. All the abovementioned hypotheſes, however, ſeem to be exceedingly imperfect. It may be granted by Wolfius and Formey, that dreams will ariſe from certain impreſſions made either on the external or internal parts of the body. But theſe impreſſions by no means produce any thing like the ſenſations we have from ſimilar ones made upon us while we are awake. Thus, if a perſon whoſe digeſtion is not very good, goes ſoon to bed after eating a large ſupper, it is not improbable that he will dream of being oppreſſed with a great weight, by a monſter, being ſuffocated, &c. Theſe dreams undoubtedly ariſe from the uneaſy ſenſations produced in the ſtomach from two great a quantity of food; but if the perſon was awake, ſuch ſenſations would produce only a ſickneſs and uneaſineſs at the ſtomach. If dreams, therefore in all caſes proceed from ſenſations, we muſt alſo ſay, that in ſleep the laws of ſenſation itſelf are altered; that thoſe connections which we look upon to be the moſt conſtant and invariable, are not ſo in reality; and thus we are led into a greater difficulty than before. For example, there is no ſenſation more invariable than that, when a man's ſtomach is oppreſſed, he ſhould feel what we call ſickneſs. This ſenſation happening in the time of ſleep according to Wolfius, produces a dream. Very true, it will do ſo; but why does not the man dream that he his ſick? What connection is there between ſickneſs, the waking ſenſation, and being oppreſſed by a weight, ſuffocated by a monſter, &c. the ſleeping ones? This difficulty ſeems inſurmountable on the hypotheſes of Wolfius and Formey.

Mr. Baxter's ſuppoſition is, in its very nature, incapable of proof. We are by no means aſcertained of the exiſtence of any immaterial beings, created ones at leaſt, that can have acceſs to our ſouls; and though we were, the ridiculous fancies that ſometimes occur in dreams are too abſurd to be ſuppoſed the work of any rational being; much leſs of thoſe who poſſeſs an higher rank in the creation than ourſelves. It muſt alſo be obſerved, that the method which this author takes to prove his hypotheſis can never be concluſive, even though every thing he contends for ſhould be granted. He inſiſts that the phantaſm, or what is properly called the viſion, in dreams, is not the work of the ſoul itſelf, and cannot be the effect of mechanical cauſes; therefore, according to him, it muſt be the effect of immechanical, or immaterial, agents operating upon the ſoul. That it is not the work of the ſoul itſelf, may readily be granted; and likwiſe that it is not the effect of ſuch mechanical cauſes as we are acquainted with: but from thence it will not follow, that it muſt neceſſarily be the effect of immaterial cauſes, unleſs we were perfectly well acquainted with the extent of all mechanical powers whatever. Nay, in many inſtances, ſuch as that before mentioned, we are certain that dreams not only may be, but actually are, the effects of mechanical cauſes, though we ſhould never be able to inveſtigate them.

The third hypotheſis ſeems alſo inadequate to ſolve the phenomena of dreaming. If this depended on a partial excitement of the brain, our ideas ought to be juſt, as that excitement could reach. Thus, ſuppoſing that part of the brain on which ſight depends, to be quite collapſed; and that on which hearing depends, to be in ſome meaſure excited; the perſon, though deprived of ſight, would hear ſounds confuſedly: but ſtill they would only be ſuch ſounds as were actually produced by external objects: and no reaſon can be aſſigned why he ſhould imagine he heard ſounds which never exiſted.

Mr. Locke, though he does not expreſly declare how dreams are excited during ſleep, ſeems to aſcribe the perfection of rational thinking to the body; and traces their origin to previous ſenſations, when he ſays; "The dreams of ſleeping men are all made up of the waking man's ideas, though for the moſt part oddly put together." He urges the incoherence, frivolouſneſs, and abſurdity, of many of our dreams, as well as the ſuppoſed fact that ſome ſleep without dreaming, as objections to the notion that men think always: to which it has been replied, that dreams may be entirely, imperfectly, or not at all remembered, according to the various degrees in which the nerves are impreſſed by the motion given to the animal ſpirits in ſleep. Ariſt. de inſomn. cap. 3. Hobb. Lev. cap. 2. & cap. 45. Locke, Eſſ. book ii. ch. i. § 10, &c. Watt's Eſſ. § 2. p. 120, &c. Dr. Hartley explains all the phenomena of the imagination by his theory of vibrations and aſſociations. Dreams, he ſays, are nothing but the imaginations or reveries of ſleeping men, and they are deducible from three cauſes, viz. the impreſſions and ideas lately received, and particularly thoſe of the preceding day, the ſtate of the body, and particularly of the ſtomach and brain, and aſſociation. Obſ. on Man, vol. i. § 5. p. 383, &c.

Before any thing can be conjectured with probability concerning the phenomena of dreaming, it is neceſſary to inveſtigate in ſome meaſure the nature of ſleep. On this ſubject it may be obſerved, that by whatever means ſleep is produced, whether naturally by fatigue, artificially by compreſſing the brain, &c.; and however different theſe kinds of ſleep may be from one another, one general effect ſtill remains the ſame; namely, that the external ſenſes are aboliſhed, and the perſon becomes totally inconſcious of whatever paſſes around him. From this general effect, which in all caſes is conſtant and invariable, ſleep may be defined, "a ſtate in which all communication is cut off between our ſentient principle and this viſible world." That the ſentient and vital principle hath its reſidence in the brain, is an opinion which in all ages hath been eſteemed very probable. If the compariſon can be allowed, it might here be ſaid, that the brain, with regard to ſenſation, hath the ſame to the nerves, that a pond or reſervoir of water hath to a number of ſmall ſtreams that flow into it and out from it. In the brain there ſeems to be a kind of general repoſitory of ſome part of thoſe ſenſations we have formerly felt; but in what manner this repoſitory is formed, we know not. Certain it is, that there the ideas are treaſured up in ſuch a manner as to be at times, and indeed moſt commonly imperceptible to ourſelves. Thus, there are many things we have done, many people we have been acquainted with, and many places we have been in, of which we are juſt now quite inſenſible, and will remain ſo till ſome circumſtance or other brings them to our remembrance. For example: Suppoſe a man has been intimately acquainted with two others who were companions, and lodged in the ſame houſe; he goes into another country, and being engaged in new purſuits, forgets both, ſo completely, that for a conſiderable time he hath perhaps never thought of them at all. But if he ſhould unexpectedly meet with one of theſe friends in the ſtreet, he will inſtantly remember the other who is at a diſtance; and this very circumſtance will bring a train of thoughts into his mind, which produces the remembrance of many things that otherwiſe perhaps would never have been thought of. Now, if we conſider what paſſes with regard to our own minds and intellectual faculties, we ſhall readily be convinced, that every thing we do remember, occurs only in conſequence of ſome external circumſtance.

The only things we can think of, are the preſent and the paſt. When we think of what is to come, we muſt combine ideas from the preſent to the paſt. If, therefore, our memory depends on a certain combination of external circumſtances immediately preſent to our view, it muſt neceſſarily follow, that the more a perſon is kept in perfect ſolitude, or removed from every thing that can affect his ſenſes, the more he will be inclined to ſleep. And, indeed, as far as this experiment can be tried, it will moſt commonly be found ſucceſsful. For, let a perſon who has ſlept his uſual time through the night be put to bed at noon-day, in a dark room, where there is nothing either to amuſe or diſturb him, and he will almoſt certainly fall aſleep in a ſhort time. Hence it would ſeem, that by whatever means our ſenſations of what is preſent, or our external ſenſes, are ſuſpended; by the ſame, our memory muſt alſo be extinguiſhed, and we become abſolutely inconſcious of exiſtence, or fall aſleep.

The ſenſe of feeling is leſs liable to deception while we are awake than any of the reſt; nevertheleſs there is one caſe which may be referred to that of dreaming, and which has been very often taken notice of. It is an imagination common to people who have loſt a limb, that they ſtill feel a pain in it, though many years after it has been ſeparated from their body. If this imagination occured only in the time of ſleep, we would have no heſitation in calling it a dream; but as it occurs while the perſons are awake, it hath been explained without thinking of any connection between it and the phenomenon of dreaming. It is certain, however, that whatever explains the one, will explain the other alſo. In the caſe of the amputated limb, the ſenſation ariſes from ſome injury offered to the nerve which had formerly gone to that limb. This produces a certain motion in the nervous fluid, that is propagated along the nerves to the brain, upon which the imagination that the limb ſtill remains immediately takes place. In like manner, if, during the time of ſleep, a ſimilar motion ſhall occur, a ſimilar imagination or dream will be the conſequence. It muſt be obſerved, however, that, in dreaming, our ſenſe of feeling is much more obſcure than thoſe of ſeeing and hearing. We dream that we ſee objects and hear ſounds pretty diſtinctly; while we ſcarce feel any thing we imagine ourſelves to touch, or carry in our hands; and as for the ſenſes of taſte and ſmell, they are ſcarce ever exerciſed in dreaming.

Dreams have in all ages been reckoned by the vulgar to have ſomething portentous in them, and to preſage future events. Indeed, there are few things about which the ſuperſtition of mankind hath more exerciſed itſelf than the interpretation of dreams. If the abovementioned ſolution of this phenomenon is allowed, it may readily be granted, that dreams may preſage diſeaſes, or changes of the weather, becauſe the nervous ſyſtem is very apt to be influenced by alterations in our atmoſphere; and no alteration in our health can poſſibly take place without producing ſome change in the nervous ſyſtem. But how they can preſage events entirely unconnected with our bodies, doth not appear; or rather it appears very plain that naturally they cannot; though the ſacred writers give us many inſtances of the knowledge of future events being conveyed to mankind in dreams, by a ſupernatural influence. From the ſolution of this phenomenon we have juſt now given, it appears, that imaginations reſembling dreams may occur as well when we are awake as when we are aſleep; and that they actually do ſo, we have many melancholy inſtances in hypochondriac and mad people.

DREDGERS, a term uſed in the admiralty courts for the fiſhers for oyſters.

DREGS *of Oil*, that coarſe and thick part of it, which ſubſides to the bottom of the veſſels in which great quantities of it are kept. This is not fit for the common uſes of the clear oil at the top, but there are ſeveral purpoſes to which it ſerves very well. Great quantities of the lees or dregs of common oil are uſed by the ſoap-boilers, principally in making the common ſoft ſoap. The leather dreſſers alſo uſe it in conſiderable quantities to ſoften the hides they are employed to prepare for the ſeveral artificers who uſe them. Some of theſe dregs are alſo uſed in the making of flambeaux, which inſtead of being made of yellow wax as pretended, are uſually compoſed of pitch, roſin, and this oil, mixed in ſuch a proportion as to make a maſs of a proper hardneſs and conſiſtence. All ſorts of oil produce more or leſs fæces and dregs, but of all others, the whale oil is obſerved to produce the largeſt quantity, and the nut oil the leaſt.

DRENCH, among farriers, a phyſical draught, or portion, given a horſe, by way of purge.

DRESSING *of Hemp and Flax*. See HEMP and FLAX.

DRESSING *of Hops*. See HOPS.

DRESSING *of Meats*, the preparing of them for food, by means of culinary fire. The deſign of dreſſing is, to looſen the texture of the fleſh, and diſpoſe it for diſſolution and digeſtion in the ſtomach. Fleſh not being a proper food without dreſſing, is alledged as an argument, that man was not intended by nature for a carnivorous, or fleſh eating animal.

The uſual operations are, roaſting, boiling, and ſtewing. In roaſting, it is obſerved, meat will bear a much greater and longer heat than either in boiling, or ſtewing; and in boiling greater and longer than in ſtewing. The reaſon is, that roaſting being performed in the open air, as the parts begin externally to warm, they extend and dilate, and ſo gradually let out part of the rarefied included air, by which means the internal ſuccuſſions, on which the diſſolution depends, are much weakened, and abated. Boiling being performed in water, the preſſure is greater, and conſequently, the ſuccuſſions to lift up the weight are proportionably ſtrong; by which means the coction is haſtened, and even in this way there are great differences; for the greater the weight of water, the ſooner is the buſineſs done.

Boiling, Dr. Cheyne obſerves, draws more of the rank, ſtrong juices from meat, and leaves it leſs nutritive, more diluted, lighter, and eaſier of digeſtion: roaſting, on the other hand, leaves it fuller of the ſtrong, nutritive juices, hard to digeſt, and needing more dilution. Strong, grown, and adult animal food, therefore, ſhould be boiled, and the younger and tenderer roaſted.

DRESSING, in ſurgery, denotes the treatment of a wound or any diſordered part. The apparatus for this purpoſe conſiſts of doſſils, tents, plaſters, compreſſes, bandages, bands, ligatures, &c. See Syſtem of SURGERY.

DRESSING *a Ship*, is the act of ornamenting a ſhip with a variety of colours, as enſigns, flags, pendants, &c. diſplayed from different parts of her maſts and rigging, on a day of feſtivity.

DRIFT *of the Foreſt*, an exact view, or examination of what cattle are in the foreſt; that it may be known whether it be overcharged, or not, and whoſe the beaſts are; and whether they are commonable beaſts, or not.

DRIFT, in navigation, denotes the angle which the line of a ſhip's motion makes with the neareſt meridian, when ſhe drives with her ſide to the wind and waves, and is not governed by the power of the helm; and alſo the diſtance which the ſhip drives on that line, ſo called only in a ſtorm.

DRILL, in mechanics, a ſmall inſtrument for making ſuch holes as punches will not conveniently ſerve for. Drills are of various ſizes, and are chiefly uſed by ſmiths and turners.

DRILL, a name given to an inſtrument uſed in the new method of horſe-hoeing huſbandry for ſowing the land. See Syſtem of AGRICULTURE, Sect. XXX. Plate I.

DRILLING, is a method of ſowing grain or ſeed of any kind, ſo that it may all be at a proper depth in the earth, which is neceſſary to its producing healthful and vigorous plants. For this purpoſe a variety of drill-ploughs have been invented and recommended.

This method, is greatly recommended in the Georgical eſſays, where we have the following obſervations and experiments. "Grain ſown by the hand, and covered by the harrow, is placed at unequal depths; the ſeeds conſequently ſprout at different times, and produce an unequal crop. When barley is ſown late, and a drought ſucceeds, the grain that was buried in the moiſture of the earth ſoon appears, while ſuch as was left near the ſurface lies baking in the heat of the ſun, and does not vegetate till plentiful rains have moiſtened the ſoil. Hence an inequality of the crop, an accident to which barley is particularly liable. The ſame obſervation, but in a more ſtriking manner, may be made upon the ſowing of turnips. It frequently happens that the huſbandman is obliged to ſow his ſeed in very dry weather, in hopes that rain will ſoon follow; and either rolls or covers it with a buſh harrow. We will ſuppoſe, that, contrary to his expectations, the dry weather continues. The ſeed, being near the ſurface, cannot ſprout without rain. The huſbandman is mortified at his diſappointment, but is ſoon ſatisfied and made eaſy by a perfect acquieſcence in what he thinks is the will of Providence. The ſcourge that he feels muſt not be placed to the diſpenſation of Providence, but has its ſource in the ignorance of the man himſelf. Had he judiciouſly buried the ſeed in the moiſt part of the ſoil with the drill plough, or harrowed it well with the common harrow, his ſeed would have vegetated in due ſeaſon, and bountifully repaid him for his toil.

"The excellence of the drill plow, is not confined to turnip ſeed; it is an uſeful inſtrument for ſowing all kinds of grain. By burying the ſeed at an equal depth, it ſecures an equal crop in all circumſtances of the weather. But this is not the only conſideration to the cultivator. It ſaves near one half of his ſeed, which is an object of importance to the tillage farmer."

The beſt inſtrument for drilling of grain, is the invention of the Rev. James Cooke, an ingenious gentleman, who has favoured us with many practical obſervations on drilling, and horſe-hoeing, with a mathematical definition to eſtabliſh his principle.

DRILLING is popularly uſed for exerciſing ſoldiers. The word is derived from the French *drille*, which ſignifies a raw ſoldier.

DRINK, a part of our ordinary food in a liquid form. The general uſe of drink is, to ſupply fluid; facilitate ſolution; and in conſequence of that, to expede the evacuation of the ſtomach, and promote the progreſs of the aliment through the inteſtines: for, by the contraction of the longitudinal fibres of the ſtomach, the pylorus is drawn up, and nothing but fluid can paſs; which by its bulk, makes a hurried progreſs through the inteſtines, and ſo determines a greater excretion by ſtool, as leſs then can be abſorbed by the lecteals. Hence a large quantity of common water has been found purgative; and, *cæteris paribus*, that aliment which is accompanied with the largeſt proportion of drink, makes the largeſt evacuation by ſtool. Here a queſtion has ariſen, about where the feculent part of the aliment is firſt remarkably collected. It is commonly thought to be in the great guts; but undoubtedly it often begins in the lower part of the ileum, eſpecially when the drink is in ſmall proportion, and when the progreſs of the aliment is ſlow; for when the contents of the guts are very fluid, they are quickly puſhed on, and reach the great guts before they depoſite any feculency. Another effect of drink is, to facilitate the mixture of the lymph, refluent from every part of the ſyſtem, with the chyle. In the blood-veſſels, where all muſt be kept fluid in order to proper mixture, drink increaſes the fluidity, and gives tenſion, by its bulk; without concomitant acrimony or too much elaſticity, and ſo ſtrength and oſcillatory motion: hence drink contributes to ſanguification, as ſometimes food gives too denſe a nutriment to be acted upon by the ſolids; and hence alſo we can ſee how drink promotes the ſecretions. Theſe are the effects of drink in general;

ral: but what has been ſaid muſt be taken with ſome limitations: for the more liquid the food, it is ſooner evacuated, and leſs nouriſhment is extracted. Hence drink is, in ſome degree, oppoſed to nouriſhment; and *cæteris paribus*, thoſe who uſe leaſt drink are moſt nouriſhed.

The drinks, in different countries, are different. Thoſe uſed among us, are water, malt liquors, wine, cyder, brandy, tea, &c. See each under its proper article. The firſt drinks of mankind were certainly water and milk; but luxury ſoon introduced the art of preparing intoxicating and inebriating drinks, out of vegetables. The vine gave the firſt of theſe liquors, after this wheat, barley, millet, oats, rice, apples, pears, and pomegranates; and after theſe the juices drained from the pine, ſycamore, and maple, were brought to this uſe; in latter times, roots, berries, and the pitch of the ſugar cane, have been employed for the ſame purpoſes. But before the uſe of the other things here mentioned, the vinous liquor made of honey and water was in the very higheſt eſtimation. The bees were natural purveyors, and their ſtores were one of the firſt delicacies probaby of the human race. The people who have ſtudied the human frame to moſt purpoſe, all agree, that among the ſtrong drinks, ſpirits and wine are the moſt pernicious; and that good water, milk, beer, and cyder, are greatly preferable to it, none of them bringing on the variety of diſorders, to which immoderate drinkers of wine and ſpirits are ſubject, ſuch as decay of ſight, trembling of the limbs, &c. Water Dr. Cheyne obſerves, is the only ſimple fluid (for there are but three more in nature, mercury, light, and air, none of which is fit for human drink) fitted for diluting, moiſtening, and cooling, the only ends of drink, appointed by nature; and happy had it been for the race of mankind, had other mixed, and artificial liquors, never been invented. Water alone is ſufficient, and effectual, for all the purpoſes of human wants in drink. Strong liquors were never deſigned for common uſe. They were formerly kept here in England, as other medicines are, in apothecaries ſhops, and preſcribed by phyſicians, as they do diſaſcordium, and Venice treacle, to refreſh the weary, ſtrengthen the weak, and raiſe the low-ſpirited. The effect of the ordinary uſe of wine and ſpirituous liquors, as natural cauſes will always produce their effects, is to inflame the blood into gout, ſtone, and rheumatiſm, fevers, pleuriſies, &c. to dry up the juices, and ſcorch and ſhrivel the ſolids. Thoſe whoſe appetite and digeſtion are good and entire, never want ſtrong liquors to ſupply them with ſpirits; ſuch ſpirits are too volatile, and fugitive, for any ſolid or uſeful purpoſes of life. Two ounces of fleſh meat, well digeſted, beget a greater ſtock of more durable and uſeful ſpirits, than ten times as much ſtrong liquors.

All ſtrong liquors are as hard to digeſt, and require as much labour of the concoctive powers, as ſtrong food itſelf. Water is the only univerſal diſſolvent, or menſtruum, and the moſt certain diluter of all bodies proper for food. There are a great many ſpirituous liquors which not only will not diſſolve, but which will harden, and make more indigeſtible, certain parts, eſpecially the ſalts of bodies, wherein their active qualities, that is, thoſe which can do moſt harm to human conſtitutions, conſiſt. And we have known perſons of tender conſtitutions, who could neither eat, nor digeſt, upon drinking wine, who, by drinking at meals common water, warmed, have recovered their appetites, and digeſtion, and have thriven, and grown plump. It is true, ſtrong liquors, by their heat, and ſtimulation on the organs of concoction, by increaſing the velocity of the motion of the fluids, and thereby quickening the other animal functions, will carry off the load that lies upon the ſtomach, with more preſent chearfulneſs. But then, beſide the future damages of ſuch a quantity of wine to the ſtomach, and the fluids, by its heat, and inflammation, the food is hurried into the habit unconnected, and lays a foundation for a fever, a fit of the cholic, or ſome chronical diſeaſe. Eſſay on Health, &c. 47, & ſeq.

With reſpect to fermented liquors, which are commonly uſed, it may be obſerved, that thoſe which are too ſtrong hurt digeſtion, and are ſo far from ſtrengthening the body, that they weaken and relax it. They keep up a conſtant fever, which exhauſts the ſpirits, heats and inflames the blood, diſpoſes to numberleſs diſeaſes, and occaſions a premature old age. But fermented liquors may be too weak, as well as too ſtrong: theſe muſt either be drank new, before the fermentation is over, and in this caſe will generate air in the bowels, and occaſion flatulencies; or they ſoon become ſtale, ſour the ſtomach, and injure digeſtion. On this account all malt liquors, cyders, &c. ſhould be ſufficiently ſtrong, to keep till they are ripe, and then they ſhould be uſed; and neither ſooner nor later. Liquors that are adulterated with a mixture of ingredients of the opiate kind, which are poiſonous in their quality, by thoſe who make them for ſale, hurt the nerves, relax and weaken the ſtomach, and ſpoil its digeſtive powers.

Sometimes we impregnate water with the *fructus acido-dulces*; and then, indeed, it acquires other qualities, of conſiderable uſe in the animal œconomy. All drinks, however, may be reduced to two heads: firſt, pure water, or where the additional ſubſtance gives no additional virtue; ſecondly, the *fermentatæ*. Of the firſt we have already ſpoken; and the latter have not only the qualities of the firſt, but alſo qualities peculiar to themſelves.

Fermented liquors are more or leſs poignant to the taſte, and better calculated to quench thirſt. Thirſt may be owing to various cauſes: firſt, to defect of fluid in the ſyſtem, which occaſions a ſcanty ſecretion in the mouth, fauces, and ſtomach; the dryneſs of the mouth and fauces will alſo in this caſe be increaſed, by their continual expoſure to the perpetual flux and reflux of the evaporating air. Secondly, thirſt depends on a large proportion of ſolid viſcid food: thirdly, on an alkaleſcent aliment, eſpecially if it has attained any thing of the putrefactive taint: fourthly, on the heat of the ſyſtem; but this ſeems to operate in the ſame manner as the firſt cauſe, giving a ſenſe of dryneſs from its diſſipation of the fluids. The fermented liquors are peculiarly adapted for obviating all theſe cauſes; ſtimulating the mouth, fauces, and ſtomach, to throw out the ſaliva and gaſtric liquor by their poignancy: by their aceſcency they are fitted to deſtroy alkaleſcent acrimony, to quench thirſt from that cauſe; by their fluidity they dilute viſcid food; though here, indeed, they anſwer no better than common water. In two ways they promote the evacuation by ſtool, and progreſs through the inteſtines; firſt, by their fluidity and bulk; ſecondly, by their aceſcency, which, uniting with the bile, forms the peculiar ſtimulus formerly mentioned. Carried into the blood-veſſels, in ſo far as they retain any of the ſaline nature, they ſtimulate the excretories, and promote urine and ſweet; correcting thus alkaleſcency, not only by mixture, but diſſipation of the degenerated fluids.

Many phyſicians, in treating of fermented liquors, have only mentioned theſe qualities, rejecting their nutritious virtue, which certainly ought to be taken in, though by expediting the evacuation by ſtool they make leſs of the nutritious parts of the aliment to be taken up, and by ſtimulating the excretories make theſe nutritious parts to be for a ſhorter time in the ſyſtem. All theſe, and many more effects, ariſe from fermented liquors. Their aceſcency ſometimes promotes the diſeaſe of aceſcency, by increaſing that of vegetables, acting as a ferment, and ſo producing flatulency, purging, cholera, &c: ſo that, with vegetable aliment, as little drink is neceſſary, the moſt innocent is pure water; and it is only with animal food that fermented liquors are neceſſary. In warmer climates, *fermentatæ* would ſeem neceſſary to obviate alkaleſcency and heat. But it ſhould be conſidered, that though fermented liquors contain an acid, yet they alſo contain alcohol; which, though it adds ſtimulus to the ſtomach, yet is extremely hurtful in the warmer climates, and wherever alkaleſcency prevails in the ſyſtem. Nature, in theſe climates, has given men an appetite for water impregnated with acid fruits, *e. g.* ſherbet; but the uſe of this needs caution, as in theſe countries they are apt to ſhun animal food, uſing too much of the vegetable, and often thus cauſing dangerous refrigerations, choleras, diarrhœas, &c.

Of varieties of fermented liquors; we ſhall only mention here the chief heads on which theſe varieties depend. Firſt, they are owing to the qualities of the ſubject, as more or leſs viſcid; and to its capacity alſo of undergoing an active fermentation, although perhaps the more viſcid be more nutritious. Hence the difference between ales and wines: by the firſt meaning fermented liquors from *farinacea*, by the ſecond from the fruits of plants. It depends, ſecondly, on the acerbity, acidity, nature, and maturation, of the fruit. Thirdly, the variety depends on the conduct of the fermentation. In general, fermentation is progreſſive, being at firſt active and rapid, detaching the fixed air or *gas ſylveſtre*, at the ſame time acquiring more acid than before. Theſe qualities of flatulency and acidity remain for ſome time; but as the fermentation goes on, the liquor becomes more perfect, no air is detached, and alcohol is produced; ſo that fermented liquors differ according to the progreſs of the fermentation, and have different effects on the ſyſtem. When fermentation is ſtopped before it comes to maturity, though naturally it proceeds in this way, yet by addition of new ferment it may again be renewed with a turbid inteſtine motion.

DRIPS, in building, a kind of ſteps, on flat roofs, to walk upon. This way of building is much uſed in Italy; where the roof is not made quite flat, but a little raiſed in the middle; with drips, or ſteps, lying a little inclining to the horizon.

DRIVE, in the ſea language. A ſhip is ſaid to drive, when an anchor being let fall, will not hold her faſt, but ſhe ſails away with the tide, and wind.

DRIVER, the name given by our ſportſmen to an inſtrument uſed in taking pheaſant powts, in the method called driving. This inſtrument conſiſts only of a parcel of ozier wands, ſuch as are uſed by the baſket-makers, which are made up into a bundle, or ſort of great whiſk, and faſtened in a handle; and to prevent their ſpreading too much at the points are tied round in one or two places in the length; with this inſtrument the ſportſman, having fixed his nets, drives the young birds into them. See DRIVING.

DRIVING, amongſt ſportſmen, a term applied to the taking of young pheaſants, and ſome other birds, in nets of an open ſtructure. The method of doing this, is, when an eye of pheaſants is found, the ground all about is to be ſearched, for finding their principal haunts. The induſtrious ſearcher will ſoon be able to make out ſome one of their paths which are beaten in the manner of ſheep tracts, only more ſlightly. When one of theſe is found, the place is to be marked by ſetting up a ſtick with another tied to its top like the hand of a road poſt, marking out the place where the path ſeems to run to. On examining the reſt of the ground thereabouts, having regard to the ſame direction, it is highly probable that ſeveral more of the ſame ſort of tracks will be found all running the ſame way. By one or other of theſe, probably the ſportſman will be led to their haunt, which he will not miſs knowing by the nakedneſs and barrenneſs of the ground, and its being covered with the dung and feathers of the young birds. When this is found, the nets are to be placed near this ſpot, looſe and circularly, in ſuch a manner, that the under part being faſtened down to the ground, the upper part may be a hollow, to give a paſſage to the young birds. When the nets are fixed, the perſon muſt go to the haunts, and call them together by the artificial noiſe of the pheaſant call, which is ſo like the real note of the pheaſant, that the powts, or young ones, will ſeldom fail being deceived by it. When they hear this, and begin to anſwer it with their chucking and piping, the call is to be ſtopped, and a perſon is to get behind them, taking the wind with himſelf, as they always run with the wind. He is to have in his hand the inſtrument called by the ſportſmen a driver.

When the perſon who carries this inſtrument perceives that he is come pretty near ſome of the powts, he muſt ſoftly beat the buſhes with the driver, or only lightly draw it over them; the little noiſe this makes will terrify theſe timorous creatures, and they will gather together in the track, and run a little way forward, and then all ſtop and turn about; on this the perſon is to make the ſame noiſe again, upon which they will run farther; and when they ſtop again, the ſame noiſe will again ſend them forward. Whatever other powts are in the way will join the main body in the fright, and the whole will be driven in this manner, like a flock of ſheep, and by a little addreſs in the ſportſman be ſent into the nets; ſo that out of a whole eye, it often happens that not one is miſſed. If in the fright the birds happen to run out of their track, and take a wrong way, then the driver is to make a raking noiſe with his inſtrument dragged along the ground, on that ſide on which they are running; this will amaze and terrify them ſo, that they will immediately ſtart back, and come into the beaten track that leads directly to their haunt. There are but two cautions neceſſary to the ſucceeding perfectly in this method of taking them: theſe are ſecrecy and patience. Whatever ſtops they make, or however tediouſly they move, the ſportſman who would make ſure of them, muſt bear with it; for over raſhneſs and hurrying will ſpoil all, and he muſt content himſelf with terrifying them by the noiſe alone, keeping himſelf carefully out of their ſight; for if they eſpy him, all the plan is diſconcerted, and they will no more move forwards, but will every one run a different way, and hide under the roots of trees, and thick buſhes, and all the art in the world will never bring them out again till night, when it will be too dark to watch them.

Driving *of Wild Foul*, is only practicable in the moulting time, which is in July and Auguſt; and it is to be done by means of a ſpaniel, well trained to the purpoſe. They are uſually indeed poor and out of fleſh at this time, but as they are always taken alive, and without any hurt, the people find it eaſy to fatten them with beaſts livers, barley, paſte, ſcalded bran, and the like; and they will on this become, in a very little time, fat and well taſted, excelling in flavour both the tame ducks, commonly kept in the yards, and the wild ducks in their natural ſtate. When the ſportſman takes the dog into places where they are not ſo frequent, he may hunt them ſingly, and the dog alone will take them. For the ſpaniel uſed for this purpoſe, ſee Dog; and the method of ſnaring them, ſee Decoy.

Driving, in metallurgy, is uſed by the refiners of ſilver to expreſs the riſing up of copper from its ſurface in red fiery bubbles. When the lead that was added for refining the ſilver is burnt away before the copper is gone from it, theſe bubbles appear very fiercely on the ſurface. They ſay, on this occaſion, that the metal drives, and then add more lead till the remainder of the copper is conſumed. Phil. Tranſ. N° 142.

DROIT, Jus, in our law-books, ſignifies right, or law.

DROMEDARY, the name of a ſpecies of camel; ſee Camel.

Drone, in entomology, a kind of male bee, larger than the common working or honey bees: it is ſo called from its idleneſs, as never going abroad to collect either honey or wax. Theſe are the males of the ſwarm; the common working bees are of no ſex at all, or rather females in diſguiſe, and the female is uſually only one in a hive, for there is reaſon to conclude, from numerous late experiments, that the queen bee lays only two kinds of eggs, thoſe that are to produce drones, and thoſe from which the working bees are to proceed. The proportions of drones to other bees in ſwarms are various; ſome having more than others.

This larger ſpecies of drones may be eaſily diſtinguiſhed from the working bees, by being nearly double their ſize. Their head is round, their eyes full, their tongue ſhort, and belly broader and more obtuſe than that of the other claſſes; they are likewiſe of a darker colour, and more thickly cloathed; and they make a much greater noiſe in flight, ſo that they may be eaſily known though unſeen. They have alſo no ſting, as the other bees have. The diſſection of the drone bee gives as great proof of its being the male, as that of the queen does of her being the female. In this creature there is no appearance of ovaries or eggs, nor any thing of the ſtructure of the common working bees, but the whole abdomen is filled with tranſparent veſſels, winding about in various ſinuoſities, and containing a white or milky fluid. This is plainly analogous to that fluid in the males of other animals, which is deſtined to render the eggs of the female prolific; and this whole apparatus of veſſels, which much reſembles the turnings and windings of the ſeminal veſſels in other animals, is plainly intended only for the preparation and retention of this matter, till the deſtined time of its being emitted on the eggs.

Drone-*Fly* or **Bee-***Fly*, a two winged fly, ſo extremely like the common bee as to be at firſt ſight not eaſily diſtinguiſhable from it. The diſtinction between the two inſects, however, beſide the different number of their wings, is, that the bee has a ſomewhat longer and leſs thick body, and the head is proportionably much ſmaller than that of the fly which ſo much reſembles them. The bee-fly alſo ever carries its wings parallel in their poſition, but without its body; whereas the bee itſelf uſually carries its wings croſſed on the back, and covers its body with them; this is not however an invariable poſture with the wings of the bee, though it is the moſt frequent one. The bee-fly is found among the flowers, as is the bee; and though it gathers no wax, it has a trunk, by means of which it ſucks the honey.

DROPAX, Δρωπαξ, in pharmacy, an external medicine in form of a plaſter, uſed to take off the hairs from any part. The dropax is of two kinds, ſimple, and compound. The ſimple is made of an ounce of dry pitch, and two drachms of oil. The compound is made with pitch, wax, colophony, common ſalt, bitumen, ſulphur vivum, pepper, euphorbium, cantharides, and caſtor. There are alſo other ways of making it, to be found in the diſpenſatories.

Drops, in medicine, a liquid remedy, whoſe doſe is eſtimated by a certain number of drops.

DROPS, in meteorology. The ſpherical figure, into which the drops of fluids conform themſelves, is a phenomenon that has a little perplexed the philoſophers. The ſolution commonly given, was, that the equable, uniform preſſure of the ambient, or incumbent atmoſphere, cloſed them into this form. But this account will no longer paſs; now that we find that the phenomenon holds in vacuo as well as in air. The Newtonian philoſophers, therefore, aſcribe it to their attraction, which being greater between the ſeveral particles of the fluids than between them and thoſe of the medium, they are, as it were, concentrated, and brought as near each other, and into as little compaſs, as may be; which cannot be without their being ſpherical.

DROPSY, Ὑδρωψ, in medicine, a preternatural collection of ſerum, or water, in ſome part of the body. The word is compounded of the Greek υδωρ, *water*. See Syſtem of Medicine.

DROPWORT, in botany. See Spiræa.

Dropwort, water, in botany. See Oenanthe.

Threlkeld mentions this plant as growing in Cumberland, where the people call it dead tongue, and uſe it as a poultice to the galled backs of their horſes. The German botaniſts do not mention it as growing among them, nor Haller in his Enumeratio Stirpium Helvetiæ; whence it ſeems to be ſeldom met with, except in England, Holland, and ſome parts of France.

DROSERA, ros ſolis, or ſun dew, in botany, a genus of the pentagynia order, belonging to the pentandria claſs of plants. The juice that exſudes from it unmixed, will deſtroy warts and corns.

DROVERS are perſons that buy cattle in one place, and drive them for ſale to another. They are to be married men, and houſholders, and to be licenſed by ſtatue 5 Eliz. cap. 12. And if they drive their cattle on the Lord's day, they ſhall forfeit 20s. by 1 Car. I. cap. 1.

DROUGHT, applied to the dry weather, want of rain; thirſt, or great want or deſire of drink.

DROWNING, ſignifies the extinction of life by a total immerſion in water. In ſome reſpects, there ſeems to be a great ſimilarity between the death occaſioned by immerſion in water, and that by ſtrangulation, ſuffocation by fixed air, apoplexies, epilepſies, ſudden faintings, violent ſhocks of electricity, or even violent falls and bruiſes. Phyſicians, however, are not agreed with regard to the nature of the injury done to the animal ſyſtem in any or all of theſe accidents. It is indeed certain, that in all the caſes above mentioned, particularly in drowning, there is very often ſuch a ſuſpenſion of the vital powers as to us hath the appearance of a total extinction of them; while yet they may be again ſet in motion, and the perſon reſtored to life, after a much longer ſubmerſion than hath been generally thought capable of producing abſolute death. It were to be wiſhed, however, that as it is now univerſally allowed, that drowning is only a ſuſpenſion of the action of the vital powers, phyſicians could as unanimouſly determine the means by which theſe powers are ſuſpended; becauſe on a knowledge of theſe means, the methods to be uſed for recovering drowned perſons muſt certainly depend.

Dr. de Haen, who hath written a treatiſe on this ſubject, aſcribes this diverſity of opinion among the phyſicians to their being ſo ready to draw general concluſions from a few experiments. Some, having never found water in the lungs, have thought that it never was there; and others, from its preſence, have drawn a contrary concluſion. Some have aſcribed the death which happens in caſes of drowning, to that ſpecies of apoplexy which ariſes from a great fullneſs of the ſtomach. But this opinion our author rejects, becauſe in 13 dogs which he had drowned and afterwards diſſected, no ſigns of ſuch a fulneſs appeared. Another reaſon is drawn from the want of the common marks of apoplexy on the diſſection of the brain; and from the actual preſence of water in the lungs. He is of opinion, that the death of drowned perſons happens in conſequence of water getting into the lungs, and ſtopping the blood in the arteries. He then diſcuſſes the queſtion how far the blowing of air into the lungs is uſeful in recovering drowned people. If their death is to be aſcribed to the water entering the lungs, this practice, he obſerves, muſt be hurtful, as it will increaſe the preſſure on the blood veſſels, or may even force the water into them; which, on the authority of Lewis's experiments, he alleges is poſſible. But, in ſpite of this reaſoning, he aſſerts, that from experience it has been found uſeful. He allows, that the practice of ſuſpending drowned people by the feet muſt be hurtful, by determining the blood too much to the head; but he obſerves, that remedies in ſome reſpects hurtful may be uſed when the advantages derived from them preponderate; and is of opinion, that the practice above mentioned may be uſeful by agitating the viſcera againſt each other, and thus renewing their motions. Cutting the larynx in order to admit air more freely to the lungs, he reckons to be of little or no uſe; but acknowledges, however, that it may ſometimes prove beneficial on account of the irritation occaſioned by the operation.

Dr. Cullen, in his letter to Lord Cathcart concerning the recovery of perſons drowned and ſeemingly dead, tells us, that "From the diſſection of drowned men, and other animals, it is known, that very often the water does not enter into the cavity of the lungs, nor even into the ſtomach, in any quantity to do hurt to the ſyſtem; and, in general, it is known, that in moſt caſes, no hurt is done to the organiſation of the vital parts. It is therefore probable, that the death which enſues, or ſeems to enſue, in drowned perſons, is owing to the ſtoppage of reſpiration, and to the ceaſing, in conſequence, of the circulation of the blood, whereby the body loſes it heat, and, with that, the cavity of the vital principle.

In the Phil. Tranſ. Vol. LXVI. Mr. Hunter gives the following theory. The loſs of motion in drowning, ſeems to ariſe from the loſs of reſpiration; and the immediate effect this has upon the other vital motions of the animal, at leaſt this privation of breathing, appears to be the firſt cauſe of the heart's motion ceaſing.

The following abſtract of the plan of the ſociety in London, called the Humane Society, and method of treatment recommended by it, will not, we apprehend, be unacceptable to our readers. This ſociety has undertaken to publiſh, in as extenſive a manner as poſſible, the proper methods of treating perſons in the unfortunate circumſtances to which they extend their relief; to diſtribute a premium of two guineas among the firſt perſons, not exceeding four in number, who attempt to recover any perſon, taken out of the water for dead, within thirty miles of the cities of London and Weſtminſter, provided they have not been longer than two hours under the water, and provided the aſſiſtants perſevere in the uſe of the means recommended for the ſpace of two hours, whether their attempts are ſucceſsful or not. Theſe rewards are alſo to include every other inſtance of ſudden death, whether by ſuffocation from noxious vapours, hanging, ſyncopies, freezing, &c. They propoſe to diſtribute in like manner four guineas wherever the patient has been reſtored to life: to give to any publican or other perſon, who ſhall admit the body into his houſe without delay, and furniſh the neceſſary accommodations, the ſum of one guinea, and to ſecure them from the charge of burial in unſucceſsful caſes; and to preſent an honorary medal to thoſe medical gentlemen, or others, who give their aſſiſtance gratis, and who are provided with a fumigator, and other neceſſaries always in readineſs, in all thoſe caſes in which they may prove inſtrumental to ſucceſs. The device on one ſide of their medal is a boy, who is repreſented blowing an extinguiſhed torch, with the hope, as the legend, *Lateat ſcintilula forſan* imports, that a little ſpark may ſtill remain. The reverſe exhibits a civic wreath, which was the Roman reward for ſaving the life of a citizen, with a blank for the name of a perſon to whom the medal may be given; the inſcription round the wreath, *Hoc pretium cive ſervato tulit,* expreſſes the merit that obtained it. The following is the method of treatment recommended by the ſociety.

1. In removing the body to a convenient place, great care muſt be taken that it be not bruiſed, nor ſhaken violently, nor roughly handled, nor carried over the ſhoulders with the head hanging downwards, nor rolled upon the ground, or over a barrel, nor lifted up by the heels. For experience proves, that all theſe methods are injurious, and often deſtroy the ſmall remains of life. The unfortunate object ſhould be cautiouſly conveyed by two or more perſons, or in a carriage upon ſtraw, lying as on a bed, with the head a little raiſed, and kept in as natural and eaſy a poſition as poſſible.

2. The body being well dried with a cloth ſhould be placed in a moderate degree of heat, but not too near a large fire. The windows or door of the room ſhould be left open, and no more perſons be admitted into it than thoſe who are abſolutely neceſſary; as the life of the patient greatly depends upon having the benefit of a pure air. The warmth moſt promiſing of ſucceſs is that of a bed or blanket properly warmed. Bottles of hot water ſhould be laid at the bottom of the feet, in the joints of the knees, and under the arm-pits; and a warming-pan, moderately heated, or hot bricks wrapped in cloths, ſhould be rubbed over the body, and particularly along the back. The natural and kindly warmth of a healthy perſon lying by the ſide of the body has been found in many caſes very efficacious. The ſhirt or cloaths of an attendant, or the ſkin of a ſheep freſh killed, may alſo be uſed with advantage. Should theſe accidents happen in the neighbourhood of a warm bath, brewhouſe, baker, glaſs-houſe, ſaltern, ſoap-boiler, or any fabrick where warm lees, aſhes, embers, grains, ſand, water, &c. are eaſily procured, it would be of the utmoſt ſervice to place the body in any of theſe, moderated to a degree of heat, but very little exceeding that of a healthy perſon.

3. The ſubject being placed in one or other of theſe advantageous circumſtances as ſpeedily as poſſible, various ſtimulating methods ſhould next be employed. The moſt efficacious are, to blow with force into the lungs, by applying the mouth to that of the patient, cloſing his noſtrils with one hand, and gently expelling the air again by preſſing the cheſt with the other, imitating the ſtrong breathing of a healthy perſon. The medium of a handkerchief or cloth, may be uſed, to render the operation leſs indelicate. If the lungs cannot be inflated in this manner, it may be attempted by blowing through one of the noſtrils, and at the ſame time keeping the other cloſe. Dr. Monro for this purpoſe recommends a wooden pipe, fitted at one end for filling the noſtril, and at the other for being blown into by a perſon's mouth, or for receiving the pipe of a pair of bellows, to be employed for the ſame purpoſe if neceſſary. Whilſt one aſſiſtant is conſtantly employed in this operation, another ſhould throw the ſmoke of tobacco up by the fundament into the bowels, by means of a pipe, or fumigator, ſuch as are uſed in adminiſtering clyſters; or by a pair of bellows, till the other inſtrument can be procured. A third attendant ſhould, in the mean time, rub the belly, cheſt, back, and arms, with a coarſe cloth, or flannel, dipped in brandy, rum, or gin, or with dry ſalt, ſo as not to rub off the ſkin; ſpirits of hartſhorn, volatile ſalts, or any other ſtimulating ſubſtance muſt alſo be applied to the noſtrils, and rubbed upon the temples very frequently. Electrical ſhocks made to paſs in different directions through the body, and particularly through the heart and lungs, have been recommended as very powerful *ſtimuli*; and from the trials that have already been made, promiſe conſiderable ſucceſs. The body ſhould at intervals be ſhaken alſo, and varied in its poſition.

4. If there be any ſigns of returning life, ſuch as ſighing, gaſping, twitching, or any convulſive motions, beating of the heart, the return of the natural colour and warmth, opening a vein in the arm or neck may prove beneficial; but the quantity of blood taken away ſhould not be large; nor ſhould an artery ever be opened, as profuſe bleeding has appeared prejudicial, and even deſtructive to the ſmall remains of life. The throat ſhould be tickled with a feather, in order to excite a propenſity to vomit; and the noſtrils alſo with a feather, ſnuff, or any other ſtimulant, ſo as to provoke ſneezings. A tea-ſpoonful of warm water may be occaſionally adminiſtered, in order to learn whether the power of ſwallowing be returned; and if it be, a table-ſpoonful of warm wine, or brandy and water, may be given with advantage; but not before, as the liquor may get into the lungs, before the power of ſwallowing returns. The other methods ſhould be continued with vigour, until the patient be gradually reſtored.

When the patient has been but a ſhort time ſenſeleſs, blowing into the lungs or bowels has been, in ſome caſes, found ſufficient; yet a ſpeedy recovery is not to be expected in general. On the contrary, the above methods are to be continued with ſpirit for two hours, or upwards, although there ſhould not be the leaſt ſymptoms of returning life. The ſame means of reſtoration are applicable to the various other caſes of ſudden death, recited in the beginning of this article.

When theſe meaſures prove unſucceſsful, the ſurgeon's laſt reſource is *Bronchotomy*, or opening the *arteria trachæa*; for perhaps the air entering freely into the lungs, through the aperture made in the canal, through which they received it in their natural ſtate, will reſtore the play of the lungs, and all the motions of the breaſt.

Mr. Hunter obſerves, that the reſtoration of breathing is all that is neceſſary to reſtore the heart's motion; for if a ſufficiency of life ſtill remains to produce that effect, we may ſuppoſe every part equally ready to move the very inſtant in which the action of the heart takes place, their actions depending ſo much upon it. What makes it very probable, that the principal effect depends upon throwing air into the lungs, is, that children in the birth, when too much time has been ſpent after the loſs of that life, which is peculiar to the fetus, loſe altogether the diſpoſition for the new life. In ſuch caſes there is a total ſuſpenſion of the actions of life; the child remains to all appearance dead; and would die, if air was not thrown into its lungs, and the firſt principle of action by that means reſtored. To put this in a clearer light, Mr. Hunter gives the reſult of ſome experiments made on a dog in 1755. A pair of double bellows were provided, which were ſo conſtructed, that, by one action, air was thrown into the lungs, and by the other the air was ſucked out which had been thrown in by the former, without mixing them together. The muzzle of theſe bellows was fixed into the trachæa of a dog, and by working them he was kept perfectly alive. While this artificial breathing was going on, the ſternum was taken off, ſo that the heart and lungs were expoſed to view. The heart then continued to act as before, only the frequency of its action was greatly increaſed. Mr. Hunter then ſtopped the motion of the bellows; and obſerved that the contraction of the heart became gradually weaker and leſs frequent, till it left off moving altogether; but, by renewing the operation, the motion of the heart alſo revived, and ſoon became as ſtrong and frequent as before. This proceſs was repeated upon the ſame dog ten times; ſometimes ſtopping for five, eight, or ten minutes. Mr. Hunter obſerved, that, every time he left off working the bellows, the heart became extremely turgid with blood, and the blood in the left ſide became as dark as that in the right, which was not the caſe when the bellows were working. Theſe ſituations of the animal, he obſerves, ſeem to be exactly ſimilar to drowning.

Mr. Hunter then obſerves that blowing air into the lungs, ſoon after the immerſion, may be ſufficient to effect a recovery; and the dephlogiſticated air of Dr. Prieſtley may prove more efficacious than common air. But if a conſiderable time, as an hour, has been loſt, it may be neceſſary to apply ſtimulating medicines, as the vapour of volatile alkali, mixed with the air; and theſe are beſt thrown in by the noſtrils, as applications of this kind to the olfactory nerves rouſe the living principle, and put the muſcles of reſpiration into action, while ſome applications to the mouth rather depreſs than rouſe, by producing ſickneſs. The larynx ſhould be at the ſame time preſſed againſt the œſophagus and ſpine, which will prevent the ſtomach and inteſtines from being too much diſtended by the air; however, the trachæa, and the aperture into the larynx, ſhould be both left perfectly free. Heat alſo is congenial with the living principle, which by increaſing the neceſſity of action, increaſes action; and to a due proportion of heat the living principle owes its vigour. Bed cloaths properly heated ſhould, therefore, be gently laid over the patient, and the ſteam of volatile alkali, or of warm balſams, and eſſential oils, may be thrown in, ſo as to come in contact with many parts of his body. The ſame ſteam may alſo be conveyed into the ſtomach by means of a hollow bougie, and a ſyringe; together with ſpirits of hartſhorn, pepper mint water, juice of horſe raddiſh, and alſo balſam, and turpentines, in ſuch ſmall quantities, as not to produce ſickneſs. Theſe may alſo be thrown up by the anus. When the heart begins to move, Mr. Hunter adviſes to leſſen the application of air to the lungs; he abſolutely forbids bleeding, becauſe it weakens the animal principle, or that principle which preſerves the body from diſſolution, and is the cauſe of all its actions, and which Mr. Hunter ſuppoſes to be inherent in the blood, and conſequently leſſens both the power and diſpoſition to action. Nothing ſhould be adminiſtered that ordinarily produces a nauſea or vomiting, or by the anus, that has a tendency to an evacuation that way; becauſe every ſuch evacuation tends to leſſen the animal powers. On this account he does not particularly recommend the fumes of tobacco, becauſe they always produce ſickneſs or purging, according to the mode of their application. He recommends the following apparatus, with a view to the purpoſes of this ſociety. Firſt, a pair of bellows; ſo contrived with two ſeparate cavities, that by opening them, when applied to the noſtrils or mouth of a patient, one cavity may be filled with the common air, and the other with air ſucking out from the lungs; and by ſhutting them again, the common air may be thrown into the lungs, and that ſucked out of the lungs diſcharged into the room. The pipe of theſe ſhould be flexible, in length a foot, or a foot and a half, and at leaſt three eighths of an inch in width; by this the artificial breathing may be continued, while the other operations, the application of the ſtimuli to the ſtomach excepted, are going on, which could not conveniently be the caſe, if the muzzle of the bellows were introduced into the noſe. The end next the noſe ſhould be double, and applied to both noſtrils. Secondly, a ſyringe with a hollow bougie, or flexible catheter, of ſufficient length to go into the ſtomach, and to convey any ſtimulating matter into it, without affecting the lungs. Thirdly, a pair of ſmall bellows, ſuch as are commonly uſed in throwing fumes of tobacco up the anus. Phil. Tranſ. vol. lxvi. part ii. p. 412. 425.

Notwithſtanding the differences in theory, however, between the phyſicians above mentioned, it is certain, that within theſe few years great numbers of drowned people have been reſtored to life, by a proper uſe of the remedies we have enumerated, and ſocieties for the recovery of drowned perſons have been inſtituted in different places. The firſt ſociety of this kind was inſtituted in Holland, where, from the great abundance of canals and inland ſeas, the inhabitants are particularly expoſed to accidents by water. The laudable and humane example of the Dutch was followed in the year 1768 by the magiſtrates of health in Milan and Venice; afterwards by the magiſtrates of Hamburgh in the year 1771, by thoſe of Paris in the year 1772, and by the magiſtrates of London in 1774.

Societies of a ſimilar nature, have been formed at Norwich, Briſtol, Liverpool, Colcheſter, and Hull, and likewiſe at Corke in Ireland. The board of Police in Scotland, has alſo intereſted itſelf in favour of the ſame benevolent deſign.

DRUG, in commerce, a general name for all ſpices, and other commodities, brought from diſtant countries, and uſed in the buſineſs of medicine, and the mechanic arts. The drugs uſed in medicine are very numerous, and make the greateſt part of the commerce of our druggiſts. Some of them grow in England, France, &c. but the greateſt part are brought from the Levant, and the Eaſt Indies. A liſt of them would be endleſs.

DRUGGET, in commerce, a ſort of ſtuff, very thin, and narrow, ſometimes all wool, and ſometimes half wool, and half thread; having ſometimes the whale, but more uſually without. Thoſe without the whale in the plain druggets are woven on a loom with two treddles, after the ſame manner as linen, camblet, &c. Thoſe with the whale, or the corded druggets, are wrought on a loom with four treddles. Thoſe are called threaded druggets, that have the woof of wool, and the warp of thread.

DRUIDS, the prieſts among the ancient Britons and Gauls. The word is formed from the Celtic, *deru*, an oak; becauſe they held that tree in the higheſt veneration.

Their antiquity is eſteemed equal to that of the Brachmans of India, the Magi of Perſia, and the Chaldees of Babylon. And whoever conſiders the ſurpriſing conformity of their doctrine, will find ſufficient reaſon to think that they all derived it from the ſame hand, we mean from Noah and his immediate deſcendants, who carried it with them at their diſperſion; for it cannot be ſuppoſed that the Britiſh druids derived their doctrine from any foreign ſect, to whom they were abſolutely unknown.

But the druids were not contented with the power annexed to the prieſthood: they introduced religion into every tranſaction both public and private, ſo that nothing could be done without their approbation; and by this means their authority was rendered almoſt abſolute. They elected the annual magiſtrates of every diſtrict, who ſhould have enjoyed during that term the ſupreme authority, and ſometimes the title of kings: but they could not even call a council without their approbation and advice; ſo that, notwithſtanding their pretended authority, they were in reality the creatures and ſlaves of the druids.

They exerciſed the ſame arbitrary power in their courts of juſtice; and whoever refuſed to ſubmit to their deciſions, were excluded from the public ſacrifices, which was conſidered as the greateſt puniſhment that could be inflicted.

Their garments were remarkably long; and, when employed in religious ceremonies, they always wore a white ſurplice. They generally carried a wand in their hands; and wore a kind of ornament enchaſed in gold about their necks, called the druid's egg. Their necks were likewiſe decorated with gold chains, and their hands and arms with bracelets; they wore their hair very ſhort, and their beards remarkably long.

They were all ſubordinate to a chief or ſovereign pontiff, ſtyled the arch-druid, choſen from among their fraternity by a plurality of voices: but, in caſe of a competition too powerful to be decided by a majority, the conteſt was determined by the ſword. He enjoyed his ſupremacy for life, had power to inſpect the conduct of kings, and either to elect or depoſe whenever he pleaſed.

It was one of the maxims of their religion, not to commit any thing to writing; but deliver all their myſteries and learning in verſes compoſed for that purpoſe. By this means their doctrines appeared more myſterious by being unknown to all but themſelves; and having no book to recur to, they were the more careful to fix them in their memory.

But what had ſtill a more direct tendency to impoſe on the public, was their pretended familiar intercourſe with the gods. And in order at once to conceal their own ignorance, and render the impoſition leſs ſuſceptible of detection, they boaſted of their great ſkill in magic, and cultivated ſeveral branches of the mathematics, particularly aſtronomy. The latter they carried to ſome degree of perfection; for they were able to fortel the times, quantities, and durations, of eclipſes: a circumſtance which could not fail of attracting reverence from an ignorant multitude, who were perſuaded that nothing leſs than a ſupernatural power was ſufficient to make ſuch aſtoniſhing predictions. They alſo ſtudied natural philoſophy, and practiſed phyſic.

They worſhipped the Supreme Being under the name of Eſus, or Heſus, and the ſymbol of the oak; and had no other temple than a wood or a grove, where all their religious rites were performed. Nor was any perſon admitted to enter that ſacred receſs, unleſs he carried with him a chain, in token of his abſolute dependence on the Deity. Indeed, their whole religion originally conſiſted in acknowledging, that the Supreme Being, who made his abode in theſe ſacred groves, governed the univerſe; and that every creature ought to obey his laws, and pay him divine homage. They conſidered the oak as the emblem, or rather the peculiar reſidence, of the Almighty; and accordingly chaplets of it were worn by the druids and people in their religious ceremonies, the altars were ſtrewed with its leaves and encircled with its branches. The fruit of it, eſpecially the miſletoe, was thought to contain a divine virtue, and to be the peculiar gift of heaven.

The conſecrated groves, in which they performed their religious rites, were fenced round with ſtones, to prevent any perſon's entering between the trees, except through the paſſages left open for that purpoſe, and which were guarded by ſome inferior druids, to prevent any ſtranger from intruding into their myſteries. Theſe groves were of different forms; ſome quite circular, others oblong. Within theſe circles were ſeveral ſmaller ones ſurrounded with large ſtones; and near the centre of theſe ſmaller circles, were ſtones of a prodigious ſize, and convenient height, on which the victims were ſlain and offered. Each of theſe being a kind of altar, was ſurrounded with another row of ſtones, the uſe of which cannot now be known, unleſs they were intended as cinctures to keep the people at a convenient diſtance from the officiating prieſt.

While the religion of the druids continued pure and unmixed with any foreign cuſtoms, they offered only oblations of fine flour ſprinkled with ſalt, and adored the Supreme Being in prayers and thankſgivings. But after they had for ſometime carried on a commerce with the Phœnicians, they loſt their original ſimplicity, adored a variety of gods, adopted the barbarous cuſtom of offering human victims, and even improved on the cruelty of other nations; uſing theſe unfortunate mortals for the purpoſes of divination, with ſuch barbarous cruelty as is ſhocking to human nature to relate. Practices like theſe ſoon rendered them ſo deaf to the voice of humanity, that on extraordinary occaſions they erected an huge hollow pile of oſier, which they filled with theſe unhappy wretches, and burnt them to their gods. Criminals were indeed choſen for this barbarous ſacrifice; but, in want of theſe, the innocent became victims to a cruel ſuperſtition.

We have already mentioned, that in their ſacred groves were ſeveral large ſtones, ſuppoſed to be the altars on which they offered their victims. Some of theſe ſtones are ſtill remaining in England, Wales, Ireland, and the iſland of Angleſey; and are of ſuch an amazing magnitude, that the bringing and rearing them was thought by the ſuperſtitious to have been the work of thoſe dæmons ſuppoſed to attend on that manner of worſhip.

Temples they had none before the coming of the Romans, nor in all probability for a long time after: for with regard to thoſe vaſt piles of ſtones ſtill remaining, they ſeem rather to have been funeral monuments than places of worſhip; eſpecially as all the ancient writers agree that their religious ceremonies were always performed in their conſecrated groves. Accordingly Tacitus, ſpeaking of the deſcent of the Romans, tells us, that their firſt care was to deſtroy thoſe groves and woods which had been polluted with the blood of ſo many human victims.

One of the chief tenets taught by the druids was the immortality of the ſoul, and its tranſmigration from one body to another; a doctrine which they conſidered as proper to inſpire them with courage, and a contempt of death. They alſo inſtructed their diſciples in ſeveral traditions concerning the ſtars and their motions, the extent of the world, the nature of things, and the power of the immortal gods. But as they never committed any of their tenets to writing, in order at once to conceal their myſterious learning from the vulgar, and exerciſe the minds of their diſciples, the greateſt part of them are now irrecoverably buried in oblivion. For a particular account of temples of the Druids, ſee Carnedde.

DRUM, is a martial muſical inſtrument by Le Clerc, ſaid to have been an Oriental invention, and to have been brought by the Arabians, or perhaps rather the Moors, into Spain.

Kettle Dbums, are two ſorts of large baſons of copper or braſs, rounded in the bottom, and covered with vellum, or goat ſkin, which is kept faſt by a circle of iron round the body of the drum, with a number of ſcrews to ſcrew up and down. They are much uſed among the horſe; as alſo in operas, oratorios, concerts, &c.

Drum, or Drummer, he that beats the drum; of whom each company of foot has one, and ſometimes two.

They are diſtinguiſhed from the ſoldiers, by cloaths of a different faſhion: their poſt, when a battalion is drawn up, is on the flanks, and on a march it is betwixt the diviſions.

Drum *Major*, is that perſon in a regiment who beats the beſt drum, commands the others, and teaches them their duty. Every regiment has a drum major.

Drum, in anatomy, or *Ear* Drum, *Tympanum*, denotes a cavity in the inner ear; thus called from the reſemblance it bears to the figure of a war-drum. Its outer extreme is covered with a membrane, by anatomiſts called alſo *tympanum*, *drum*; but, more properly, *membrana tympani*. The office of this *drum* or *membrana tympani*, has been greatly controverted by anatomiſts. The account beſt warranted is, that being a medium for the conveyance of the ſound to the auditory nerve, by its different degrees of tenſion, it ſerves to modify the ſound, and propagate it to the nerve well proportioned, and commenſurate thereto. See Syſtem of Anatomy, Part VI. Sect. X. and Plate on the Organs of Senſe, *Fig.* 6.

DRUNKENNESS, *Ebriety*, phyſically conſidered, conſiſts in a preternatural compreſſion of the brain, and a diſcompoſure of its fibres: occaſioned by the fumes, or ſpirituous parts of liquors. It is accounted for thus: an immoderate quantity of wine taken into the ſtomach is there heated, and undergoes a kind of efferveſcence; which ariſes the more readily, as the liquor abounds the more in ſulphur. By this action it becomes attenuated and rarefied; ſo that the groſſer parts being left behind, its finer parts are fitted to penetrate, and ſhoot through the veins to the brain, or are conveyed through the veins to the heart; whence, after a farther heat and rarefaction, they are ſent through the carotid arteries, &c. to the brain: hence neceſſarily ariſes a repletion of the meninges of the brain, and a compreſſion of the fibres of the brain itſelf, from the freſh ſtock of rarefied ſulphur continually aſcending into them: hence, alſo, ariſe obſtruction of the pores or paſſages of the brain, a frequent and diſorderly pulſation of the fibres, and the other ſymptoms of this diſtempered ſtate. Hence it is, that all liquors will not give drunkenneſs; but only ſuch as, by their ſulphur, or ſpirit, are diſpoſed for an efferveſcence in the ſtomach and heart, to diffuſe their ſubtle attenuated parts plentifully to the brain.

It is a popular miſtake, that the only remedy for gluttony, is drunkenneſs; or that the cure of a ſurfeit of meat, is a ſurfeit of of wine; than which nothing can be more contrary to nature.

The ancient Lacedæmonians uſed to make their ſlaves frequently drunk, to give their children an averſion and horror for this vice. The Indians hold drunkenneſs a ſpecies of madneſs; and in their languages, the ſame term *ramjam*, that ſignifies *drunkard*, ſignifies alſo a *phrenetic*.

DRY. A dry air, *cæteris paribus*, leſſens the weight of the human body, and the contrary quality increaſes it.

DRYADES, Dryads, in the heathen theology, the nymphs of the woods; a ſort of imaginary deities, which the ancients believed to inhabit the woods and groves, and to hide themſelves under the bark of the oak, called by the Greeks δϱυς.

The dryades differed from the hamadryades, in that theſe latter were attached to ſome particular tree, with which they were born, and with which they died; whereas the dryades were the goddeſſes of the trees and woods in general, and lived at large, in the middle thereof. For though δρυς properly ſignifies an oak, it was alſo uſed for tree in general.

We likewiſe find mention made, in divers authors, of a kind of propheteſſes, or witches, among the Gauls, called dryades, or rather druides.

DRYERS, in painting, are ſubſtances ſo called from their uſe in remedying the fault of oils, which dry too ſlowly.

DUCAL, in general, ſomething belonging to a duke. The letters patent granted by the ſenate of Venice, are called ducals: ſo alſo are the letters wrote in the name of the ſenate, to foreign princes. The denomination of ducal is derived hence; that, at the beginning of ſuch patents, the name of the duke, or doge, is wrote in capitals, thus, *N ——— Dei Gratia Dux Venetiarum*, &c. The date of ducals is uſually in Latin, but the body is in Italian.

Ducat, a foreign coin, either of gold or ſilver, being about the ſame value with the Spaniſh piece of eight, or a French crown, of four ſhillings and ſix pence ſterling, when of ſilver; and twice as much, when of gold.

The Spaniards have no ducats of gold; but, in lieu thereof, they make uſe of the ſilver one; which, with them, is no real ſpecies, but only a money of account, like our pound. The ſilver ducats of Florence ſerve there for crowns.

DUCATOON, a ſilver coin, ſtruck chiefly in Italy; particularly at Milan, Venice, Florence, Genoa, Lucca, Mantua, and Parma; though there are alſo Dutch and Flemiſh ducatoons. They are all nearly on the ſame footing; and, being a little both finer and heavier than the piece of eight, are valued at two-pence or three pence more, viz. at about four ſhillings and eight pence ſterling.

There is alſo a gold ducatoon, ſtruck and current chiefly in Holland: it is equivalent to twenty florins, on the footing of one ſhilling and eleven pence halfpenny the florin.

DUCK, *Anas*, in ornithology, the name of a very large genus of birds belonging to the 9th order, Anſeres, and the 2d diviſion. See Anas, and Decoy.

This fowl is furniſhed with a peculiar ſtructure of veſſels about the heart, which enable it to live without reſpiration a conſiderable time under water, as is neceſſary for it in diving. This made Mr. Boyle think it a more proper object for experiments by the air pump, than any of the other birds. A full grown duck being put into the receiver of the air pump, of which ſhe filled one third part, and the air exhauſted, the creature ſeemed to bear it better for the firſt moments, than a hen or other ſuch fowl; but after about a minute, ſhe gave great ſigns of diſcompoſure, and in leſs than two minutes her head fell down, and ſhe appeared dying, till revived by letting in the air. Thus, whatever facility of diving, this and other water fowl may have, it does not appear that they can ſubſiſt without air for reſpiration, any longer than other animals. A young callow duck was afterwards tried in the ſame manner, and with the ſame ſucceſs, being reduced very near death in leſs than two minutes. But it is obſervable, that both birds ſwelled extremely on the pumping out of the air, ſo as to appear much larger to the ſpectators, eſpecially about the crop. It not being intended that any water fowl ſhould live in an exceedingly rarified air, but only be able to continue on occaſion ſome time under water; nature, though ſhe has provided them with the means of this, has done nothing for them in regard to the other.

The ſtrongeſt inſtance of this creature's being calculated to live any where, we have in the accounts of the blind ducks of the Zirchnitzer lake in Carniola. It is now well known, that this lake communicates with another lake under ground in the mountain Savornick, and fills or empties itſelf according to the fulneſs or emptineſs of that lake; the waters of the upper lake running off at the time of its emptying by large holes in the bottom, and that in vaſt quantities. The ducks, which are very plentiful in the water, are often carried down with it, and forced into the ſubterraneous lake the waters retire to. In this unnatural habitation, many of them doubtleſs periſh, but ſome remain alive; theſe become blind, and loſe all their feathers, and in the next filling of the lake, both they and vaſt numbers of fiſh are thrown up with the water. They are fat at this time, but make a ſtrange appearance in their naked ſtate, and are eaſily caught, for want of ſight to avoid the danger. In about a fortnight they recover their ſight and their feathers, and are then of the ſize of a common wild duck, but of a black colour, having a white ſpot upon their forehead. When opened, on being taken at their firſt coming up in their blind ſtate, their ſtomachs are found full of ſmall fiſhes, ſomewhat reſembling weeds. It ſeems from this, that they cannot be abſolutely blind, but that the degree of light to which they ſeem accuſtomed in their dark habitation, had formed their eyes to ſee by that ſmall quantity, ſo well as to get their food by it; and their blindneſs on coming into broad day light again, is no other than that of a man who has been long in the dark, on having in an inſtant a large blaze of candles ſet juſt under his eyes. The eye in neither caſe can bear the ſudden change, and muſt be habituated to it, before it can ſee objects by it. Theſe blind ducks are not only caſt up in this lake, but after great rains they are frequently thrown up at a hole in the mountain Storſeg, near the town of Laas. The water guſhing out at this hole with great force on theſe occaſions, brings away with it theſe blind and bald ducks; and their frequency on theſe occaſions in theſe places, makes them eſteemed no rarity; but the common people underſtand that there are under ground lakes, which they inhabit, and out of which they are thus thrown. Phil. Tranſ. N° 191.

DUCKING, a penalty, which veteran ſailors pretend to inflict on thoſe who, for the firſt time, paſs the tropic of Cancer, the equator, or the ſtreights of Gibraltar, in conſequence of their refuſal or incapacity to pay the uſual fine, levied on this occaſion.

DUCT, Ductus, in anatomy, is applied in a general ſenſe to all the canals, or tubes, in the animal body, as veins, arteries, &c. through which the humours or juices are conveyed. Duct has alſo a more immediate application to ſeveral particular veſſels: as the

DUCTUS *Alimentalis*, a name given by Dr. Tyſon to the gula, ſtomach, and inteſtines; all which make but one continued canal, or duct. This duct he makes the proper characteriſtic of an animal.

Ductus, *Chyliferus*, or *Roriferus*, the ſame as *ductus thoracicus*, or thoracic duct. See Syſtem of Anatomy, Plate V. on the Viſcera, *Fig*. 4. letter H.

Ductus *Lachrymales*, the excretory veſſels of the glandulæ lachrymales, ſerving for the effuſion of tears. See Syſtem of Anatomy. Part VI. Sect. XI.

Ductus *Pancreaticus*, a little canal, ariſing from the pancreas, and opening into the duodenum; ſerving to diſcharge the pancreatic juice into the inteſtines. See Syſtem of Anatomy, Part V. Sect. VIII.

DUCTILITY, in phyſics, a property poſſeſſed by certain ſolid bodies, which conſiſts in their yeilding to percuſſion, or preſſure, and in receiving different forms without breaking.

Some bodies are ductile both when they are hot and when they are cold, and in all circumſtances. Such are metals, particularly gold and ſilver. Other bodies are ductile only when heated to a ſufficient degree; ſuch as wax and other ſubſtances of that kind, and glaſs. Other bodies, particularly ſome kinds of iron, called by the workmen red-ſhort, braſs and ſome other metallic mixtures, are ductile only when cold, and brittle when hot. The degrees of heat requiſite to produce ductility in bodies of the firſt kind, vary according to their different natures. In general, the heat of the body muſt be ſuch as is ſufficient to reduce it to a middle ſtate betwixt ſolidity and perfect fuſion. As wax, for inſtance, is fuſible with a very ſmall heat, it may be rendered ductile by a ſtill ſmaller one; and glaſs, which requires a moſt violent heat for its perfect fuſion, cannot acquire its greateſt ductility until it is made perfectly red-hot, and almoſt ready to fuſe. Laſtly, ſome bodies are made ductile by the abſorption of a fluid. Such are certain earths, particularly clay. When theſe earths have abſorbed a ſufficient quantity of water, to bring them into a middle ſtate betwixt ſolidity and fluidity, that is to the conſiſtence of a conſiderably firm paſte, they have then acquired their greateſt ductility. Water has preciſely the ſame effect upon them in this reſpect, that fire has upon the bodies above mentioned.

DUEL, a ſingle combat, at a time and place appointed, in conſequence of a challenge. This cuſtom came originally from the northern nations, among whom it was uſual to decide all their controverſies by arms. Both the accuſer and accuſed gave pledges to the judges on their reſpective behalf; and the cuſtom prevailed ſo far amongſt the Germans, Danes, and Franks, that none were excuſed from it but women, ſick people, cripples, and ſuch as were under 21 years of age, or above 60. Even eccleſiaſtics, prieſts, and monks, were obliged to find champions to fight in their ſtead. The puniſhment of the vanquiſhed was either death, by hanging or beheading; or, mutilation of members, according to the circumſtances of the caſe. Duels were at firſt admitted not only on criminal occaſions, but on ſome civil ones for the maintenance of rights to eſtates, and the like: in latter times, however, before they were entirely aboliſhed, they were reſtrained to theſe four caſes. 1. That the crime ſhould be capital. 2. That it ſhould be certain the crime was perpetrated. 3. The accuſed muſt by common fame be ſuppoſed guilty. And, 4. The matter not capable of proof by witneſſes.

Duel, at preſent, is uſed for ſingle combat on ſome private quarrel; and muſt be premeditated, otherwiſe it is called a rencounter. If a perſon is killed in a duel, both the principals and ſeconds are guilty whether the ſeconds engage or not. It is alſo a very high offence to challenge a perſon either by word or letter, or to be the meſſenger of a challenge. The ſevere edicts made by Lewis XIV. againſt duels have in a great meaſure put a ſtop to the practice in France.

The general practice of duelling, in this laſt ſenſe, took its riſe in the year 1527, at the breaking up of a treaty between the emperor Charles V. and Francis I. The former deſired Francis's herald to acquaint his ſovereign, that he would henceforth conſider him not only as a baſe violator of public faith, but as a ſtranger to the honour and integrity becoming a gentleman. Francis, too high-ſpirited to bear ſuch an imputation, had recourſe to an uncommon expedient to vindicate his character. He inſtantly ſent back the herald with a cartel of defiance, in which he gave the emperor the lie in form, challenged him to ſingle combat, requiring him to name the time and place of the encounter, and the weapons with which he choſe to fight. Charles, as he was not inferior to his rival in ſpirit or bravery, readily accepted the challenge; but after ſeveral meſſages concerning the arrangement of all the circumſtances relative to the combat, accompanied with mutual reproaches bordering on the moſt indecent ſcurrility, all thoughts of this duel, more becoming the heroes of romance than the two greateſt monarchs of their age, were entirely laid aſide.

The example of two perſonages ſo illuſtrious, drew ſuch general attention, and carried with it ſo much authority, that it had conſiderable influence in introducing an important change in manners all over Europe. Duels, as has already been obſerved, had been long permitted by the laws of all the European nations; and, forming a part of their juriſprudence, were authoriſed by the magiſtrate on many occaſions, as the moſt proper method of terminating queſtions with regard to property, or of deciding in thoſe which regarded crimes. But ſingle combats being conſidered as ſolemn appeals to the omniſcience and juſtice of the Supreme Being, they were allowed only in public cauſes, according to the preſcription of law, and carried on in a judicial form. Men, accuſtomed to this manner of deciſion in courts of juſtice, were naturally led to apply it to perſonal and private quarrels. Duels, which at firſt could be appointed by the civil judge alone, were fought without the interpoſition of his authority, and in caſes to which the laws did not extend. The tranſaction between Charles and Francis ſtrongly countenanced this practice. Upon every affront or injury which ſeemed to touch his honour, a gentleman thought himſelf entitled to draw his ſword, and to call on his adverſary to make preparation. Such an opinion, introduced among men of fierce courage, of high ſpirit, and of rude manners, where offence was often given, and revenge was always prompt, produced moſt fatal conſequences. Much of the beſt blood in Chriſtendom was ſhed; many uſeful lives were loſt; and, at ſome periods, war itſelf hath hardly been more deſtructive than theſe conteſts of honour. So powerful, however, is the dominion of faſhion, that neither the terror of penal laws, nor reverence for religion, have been able entirely to aboliſh a practice unknown among the ancients, and not juſtifiable by any principle of reaſon; though at the ſame time it muſt be admitted, that to this abſurd cuſtom we muſt aſcribe, in ſome degree, the extraordinary gentleneſs and complaiſance of modern manners, and that reſpectful attention of one man to another, which at preſent render the ſocial intercourſes of life far more agreeable and decent than among the moſt civilized nations of antiquity.

DUKE is either the title of a ſovereign prince, as the duke of Savoy, Parma, &c. the grand duke of Tuſcany, Muſcovy, &c.; or it is the title of honour and nobility next below princes. The commanders of armies in time of war, the governors of provinces and wardens of marches in times of peace, were called duces under the later emperors. The Goths and Vandals divided all Gaul into duchies and counties, the governors of which they ſometimes call duces, and ſometimes comites. In France, under the ſecond race of kings, though they retained the name and form of ducal government, there were ſcarce any dukes except thoſe of Burgundy, Aquitain, and France.

In Britain, a duke, though, in reſpect of his title of nobility, he is inferior in point of antiquity to many others, yet is ſuperior in rank to all of them; his being the firſt title of dignity after the royal family. Among the Saxons, the Latin name of dukes, *duces*, is very frequent; and ſignified, as among the Romans, the commanders or leaders of their armies. But after the Norman conqueſt, which changed the military polity of the nation, the kings themſelves continuing for many generations dukes of Normandy, they would not honour any ſubject with that title till the time of Edward III.; who claiming to be the king of France, and thereby loſing the ducal in the royal dignity, in the 11th year of his reign created his ſon, Edward the black prince, duke of Cornwall; and many, of the royal family eſpecially, were afterwards raiſed to the ſame honour. However, in the reign of Queen Elizabeth, A. D. 1572, the whole order became utterly extinct: but it was revived about 50 years afterwards by her ſucceſſor, who was remarkably prodigal of honours, in the perſon of George Villiers duke of Buckingham.

A duke is created by patent, cincture of ſword, mantle of ſtate, impoſition of a cap and coronet of gold on his head, and a verge of gold put into his hand. His title is Grace; and, in the ſtyle of the heralds, Moſt high, potent, high-born, and noble prince. For the different dukes of Great Britain and Ireland, ſee Syſtem of PEERAGE.

DULCIFYING, in chymiſtry, is the ſweetening any matter impregnated with ſalts, by frequently waſhing it in pure water.

DULCIMER, a muſical inſtrument, in the ſhape of a ſmall cheſt or box, with ſtrings on the lid of it.

DULWICH *Water*, a well known mineral water near London. It contains a kind of cathartic bitter ſalt: it ſeems not to have any iron in it. Phil. Tranſ. N° 461. § 22.

DUMBNESS, the privation of the faculty of ſpeech. The moſt general, or rather the ſole cauſe of dumbneſs, is the want of the ſenſe of hearing. The uſe of language is originally acquired by imitating articulate ſounds. From this ſource of intelligence, deaf people are entirely excluded: they cannot acquire articulate ſounds by the ear: unleſs, therefore, articulation be communicated to them by ſome other medium, theſe unhappy people muſt for ever be deprived of the uſe of language; and as language is the principal ſource of knowledge, whoever has the misfortune to want the ſenſe of hearing, muſt remain in a ſtate little ſuperior to that of the brute creation. Deafneſs has in all ages been conſidered as ſuch a total obſtruction to ſpeech, or written language, that an attempt to teach the deaf to ſpeak or read has been uniformly regarded as impracticable, till Doctor Wallis and ſome others have of late ſhewn, that although deaf people cannot learn to ſpeak or read by the direction of the ear, there are other ſources of imitation, by which the ſame effect may be produced. The organs of hearing and of ſpeech have little or no connection. Perſons deprived of the former generally poſſeſs the latter in ſuch perfection, that nothing further is neceſſary, in order to make them articulate, than to teach them how to uſe theſe organs. This indeed is no eaſy taſk; but experience ſhews that it is practicable. See DEAFNESS.

Mr. Thomas Braidwood, of Edinburgh, is perhaps the firſt who ever brought this ſurpriſing art to any degree of perfection. He began with a ſingle pupil in 1764; and for ſome years paſt, he has taught many people born deaf, to ſpeak diſtinctly, to read, to write, to underſtand figures, the principles of religion and morality, &c. This, at firſt ſight, may appear to be altogether incredible; but the fact is certain. Mr. Braidwood has, at preſent, a conſiderable number of deaf pupils, ſome of them above 20 years of age, all making a rapid and amazing progreſs in thoſe uſeful branches of education.

Mr. Braidwood's principal difficulty, after he had diſcovered this art, was to make people believe in the practicability of it. He advertiſed in the public papers; he exhibited his pupils to many noblemen and gentlemen; ſtill he found the generality of mankind unwilling to believe him. A remarkable inſtance of this incredulity occured ſome years ago. A gentleman in England ſent a deaf girl of his to Mr. Braidwood's care. A year or two afterwards, Mr. Braidwood wrote to the father, that his daughter could ſpeak, read, and write diſtinctly. The father returned an anſwer, begging Mr. Braidwood's excuſe, as he could not believe it; however, he deſired a friend of his, who was occaſionally going to Edinburgh, to call on Mr. Braidwood, and inquire into the truth of what he had wrote him; he did ſo; converſed with Mr. Braidwood, ſaw the young lady, heard her read, ſpeak, and anſwer any queſtions put to her. On his return, he told the father the ſurpriſing progreſs his child had made; but ſtill the father thought the whole an impoſition: the girl herſelf wrote to her father, but he looked upon the letter as a forgery. About this time the father died: and the mother ſent an uncle and couſin of the deaf lady's from Shrewſbury, in order to be ſatisfied of the truth. When they arrived, Mr. Braidwood told the girl her uncle and couſin were in the parlour; and deſired her to go and aſk them how they did, and how her mother and other friends did. The friends were aſtoniſhed, and could hardly credit their own ears and eyes.

We have converſed with Mr. Braidwood, concerning the nature and method of teaching this wonderful art: he ſeems to be very deſirous of communicating and tranſmitting his diſcovery to poſterity; but ſays, and, from the nature of the thing, we believe it to be true, that he cannot communicate it ſo fully in writing as to enable any other perſon to teach it. The firſt thing in the method is, to teach the pupil to pronounce the ſimple ſounds of the vowels and conſonants. We have even ſeen him performing this operation; but are unable to give a clear idea of it. He pronounces the ſound of *a* ſlowly, pointing out the figure of the letter at the ſame time; makes his pupil obſerve the motion of his mouth and throat; he then put his finger into the pupil's mouth, depreſſes or elevates the tongue, and makes him keep the parts in that poſition; then he lays hold of the outſide of the windpipe, and gives it ſome kind of ſqueeze, which it is impoſſible to deſcribe; all the while he is pronouncing *a*, the pupil is anxiouſly imitating him, but at firſt ſeems not to underſtand what he would have him to do. In this manner he proceeds, till the pupil has learned to pronounce the ſounds of the letters. He goes on in the ſame manner to join a vowel and a conſonant, till, at length the pupil is enabled both to ſpeak and read.

That Mr. Braidwood is capable of teaching his pupils not only the mere pronunciation, but alſo to underſtand the meaning of what they read, may be aſcertained by a converſation with any of his pupils. Of this Mr. Pennant gives a remarkable inſtance in a young lady of about 13 years of age, who had been ſome time under the care of Mr. Braidwood. "She readily apprehended (ſays he) all I ſaid, and returned me anſwers with the utmoſt facility. She read; ſhe wrote well. Her reading was not by rote. She could clothe the ſame thoughts in a new ſet of words, and never vary from the original ſenſe. I have forgot the book ſhe took up, or the ſentences ſhe made a new verſion of; but the effect was as follows:

"*Original paſſage.* Lord Bacon has divided the whole of human knowledge into hiſtory, poetry, and philoſophy; which are referred to the three powers of the mind, memory, imagination, and reaſon.

"*Verſion.* A nobleman has parted the total or all of man's ſtudy, or underſtanding, into an account of the life, manners, religion or cuſtoms of any people or country; verſe, or metre; moral or natural knowledge: which are pointed to the three faculties of the ſoul or ſpirit; the faculty of remembering what is paſt, thought or conception, and right judgment."

It is altogether in vain for us to attempt to ſay any more concerning the mode of operation. Mr. Braidwood undertakes every deaf perſon, who is not at the ſame time fooliſh or idiotical. The greateſt misfortune is, that this art is confined to a ſingle man, and his pupils muſt live in the houſe with him for ſome years. The expence neceſſarily attending education of this kind, excludes all but people in opulent circumſtances from deriving any advantage from it. Mr. Braidwood ſays, that the only way for preſerving the art, and communicating it to a number, is to take people in the way of apprentices: this he is unable to do at his own expence. What a pity, that ſuch a curious and uſeful art ſhould live and die with a ſingle man! There are many ſums applied in this kingdom, both by government and private perſons, to leſs important purpoſes, than the preſervation and extenſion of the art of raiſing a great number of our fellow creatures from the rank of brutes, to that of reaſonable beings and uſeful members of ſociety.

DUMOSÆ, (from *dumus, a buſh*), an order of plants in the *Fragmenta methodi naturalis* of Linnæus, containing the following genera, viz. *Viburnum, Tinus, Opulus, Sambucus, Rondeletia, Bellonia, Caſſine, Ilex, Tomax, &c.*

DUNDIVER, in ornithology, the name of a water fowl; according to Linnæus, it belongs to the 28th genus, called Mergus. See MERGUS.

DUNG, in agriculture, &c. All kinds of dung contain ſome matter, which, when mixed with the ſoil, ferments therein, and, by that fermentation, diſſolves the texture of the earth, and divides and crumbles its particles very much. This is the real uſe of dung in agriculture; for, as to the pure earthy part of it, the quantity is ſo very ſmall, that after a perfect putrefaction, it bears an extremely inconſiderable proportion to that of the earth it is intended to manure. See Syſtem of AGRICULTURE, Sect. II.

DUNG-WORMS, a ſpecies of fly-worms, of a ſhort and ſomewhat flat body, found in great plenty among the cow-dung in the months of September and October. Theſe have all their metarmorphoſes into the fly-ſtate, performed within a ſhell of their own ſkin.

DUODECIMO, a thing divided into twelve parts. A book is ſaid to be in duodecimo, when twelve of its leaves make a ſheet of paper.

DUODENA *Arteria*, and *Vena*, a branch of an artery, which the duodenum receives from the cœliac; to which anſwers a vein of the ſame name, returning the blood to the porta.

DUODENUM, in anatomy, the firſt of the *inteſtina tenuia*, or ſmall guts; being that which receives the food half chylified from the ſtomach. See Syſtem of ANATOMY, Part V. Sect. VI.

It has its name *duodenum*, as being above twelve fingers breadth long; on which account, ſome call it *dodeea, dactylum*.

The deſcription and draughts of the *duodenum*, as given by moſt anatomiſts, appearing faulty, Mr. Monro has endeavoured to rectify their omiſſions and miſtakes in the Med. Eſſ. Edinb. vol. iv. Art. 11.

This inteſtine is ſometimes found ſo large, as to be called *ventriculus ſuccenturiatus*.

Authors ſeldom take notice of the duodenum as the ſeat or cauſe of any particular diſeaſe; but its diſtention and preſſure on the many veſſels to which it is contiguous, may diſturb the functions of the animal œconomy; and accordingly it is the ſource of many diſorders, which may be relieved by emetics and purgatives.

DUPLICATE, a ſecond inſtrument, or act in writing; or a tranſcript, or copy of another. The word is formed from the latin *dupluma*, or *duplum*, double. It is uſual to ſend a duplicate, when it is apprehended the firſt diſpatch, &c. is loſt.

Duplicate, in chancery, is particularly uſed for a ſecond letter patent granted by the lord chancellor, in a caſe where he had formerly done the ſame.

Duplicate *Ratio*, the ratio between the ſquares of two quantities. Thus the duplicate ratio of *a* to *b* is the ratio of *a a* to *b b*, or of the ſquare of *a* to the ſquare of *b*. See Syſtem of Geometry.

DUPLICATURE, in anatomy, a doubling or folding of membranes, or other like parts. Such are the duplicatures of the peritonæum, of the omentum, of the pleura, &c.

DURA *Mater*, or *Menix*, a ſtrong, thick membrane, which lines or covers all the inner cavity of the cranium, and includes the whole brain; being itſelf lined on its inner, or concave, ſide, by the pia mater, or meninx tenuis. See Syſtem of Anatomy, Part VI. Sect. I. and Plate II. *Fig.* 3.

DURATION, an idea we get by attending to the fleeting, and perpetual periſhing parts of ſucceſſion. See Metaphysics.

Duration, as marked by certain periods and meaſures, is what we moſt properly call time. See Time.

DUST, minute and almoſt inſenſible particles broken off from any hard body. Thoſe broken from ſtones, or formed of extremely ſmall ſtones are more properly called ſand. The ſubtle matter of Des Cartes is a ſort of duſt produced by the colliſion of the matter of the ſecond element.

Gold and *Lead* Dust. See the reſpective Articles.

DUTCHY, in geography, an appellation given to the dominions of a duke.

DUTY, in general, denotes any thing that one is obliged to perform.

Duty, in a moral ſenſe. See Moral Philosophy.

Duty, in polity and commerce, ſignifies the impoſt laid on merchandizes, at importation or exportation, commonly called the duties of cuſtoms; alſo the taxes of exciſe, ſtamp-duties, &c. See Customs.

The principles on which all duties and cuſtoms ſhould be laid on foreign merchandizes which are imported into theſe kingdoms, are ſuch as tend to cement a mutual friendſhip and traffic between one nation and another; and therefore due care ſhould be taken in the laying of them, that they may anſwer ſo good an end, and be reciprocal in both countries; they ſhould be ſo laid as to make the exports of this nation at leaſt equal to our imports from thoſe nations wherewith we trade, ſo that a balance in money ſhould not be iſſued out of Great Britain, to pay for the goods and merchandizes of other countries; to the end that no greater number of our landholders and manufactures ſhould be deprived of their revenues ariſing from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exportations to ſuch countries. Theſe are the national principles on which all our treaties of commerce with other countries ought to be grounded.

Duty, in the military art, is the exerciſe of thoſe functions that belong to a ſoldier; with this diſtinction, that mounting guard, and the like, where there is no enemy directly to be engaged, is called duty; but marching to meet and fight an enemy is called going on ſervice.

DUUMVIR, a general appellation among the ancient Romans, given to magiſtrates, commiſſioners, and officers, where two were joined together in the ſame function. So that they had almoſt as many duumviri, as they had officers joined two by two in commiſſion.

There are duumviri to direct the building, repairing, and conſecrating, of temples and altars; capital duumviri, who took cognizance of crimes, and condemned to death; duumviri of the marine, or navy, &c.

DUUMVIRATE, Duumviratus, the magiſtrature, office, or dignity, of the duumviri.

DWALE, or Dwal, in heraldry, the herb nightſhade; uſed by ſuch as blazon with flowers and herbs, inſtead of colours and metals, for ſable, or black.

DWARF, in general, an appellation given to things greatly inferior in ſize to that which is uſual in their ſeveral kinds: thus there are dwarfs of the human ſpecies, dwarf-dogs, dwarf-trees, &c.

The Romans were paſſionately fond of dwarfs, whom they called *nani* or *nanæ*, inſomuch that they often uſed artificial methods to prevent the growth of boys deſigned for dwarfs, by incloſing them in boxes, or by the uſe of tight bandages. Auguſtus's niece, Julia, was extremely fond of a dwarf called Sonopas, who was only two feet and an hand breadth high. We have many other accounts of human dwarfs, but moſt of them deformed in ſome way or other beſides the ſmallneſs of their ſize. Many relations alſo concerning dwarfs we muſt neceſſarily look upon to be fabulous, as well as thoſe concerning giants. The following hiſtory, however, which we have reaſon to look upon as authentic, is too remarkable not to be acceptable to the generality of our readers.

Jeffery Hudſon, the famous Engliſh dwarf, was born at Oakham in Rutlandſhire in 1619; and about the age of ſeven or eight, being then but 18 inches high, was retained in the ſervice of the duke of Buckingham, who reſided at Burleigh on the Hill. Soon after the marriage of Charles I. the king and queen being entertained at Burleigh, little Jeffery was ſerved up to table in a cold pye, and preſented by the ducheſs to the queen, who kept him as her dwarf. From 7 years of age till 30, he never grew taller; but after 30, he ſhot up to three feet nine inches, and there fixed. Jeffery became a conſiderable part of the entertainment of the court. Sir William Davenant wrote a poem called Jeffreidos, on a battle between him and a turkey-cock; and in 1638 was publiſhed a very ſmall book, called the New Year's Gift, preſented at court by the lady Parvula to the lord Minimus (commonly called Little Jeffery) her majeſty's ſervant, &c. written by Microphilus, with a little print of Jeffery prefixed. Before this period, Jeffery was employed on a negociation of great importance: he was ſent to France to fetch a midwife for the queen; and on his return with this gentlewoman, and her majeſty's dancing-maſter, and many rich preſents to the queen from her mother Mary de Medicis, he was taken by the Dunkirkers. Jeffery, thus made of conſequence, grew to think himſelf really ſo. He had borne with little temper the teazing of the courtiers and domeſtics, and had many ſquabbles with the king's gigantic porter. At laſt, being provoked by Mr. Crofts, a young gentleman of family, a challenge enſued: and Mr. Crofts coming to the rendezvous armed only with a ſquirt, the little creature was ſo enraged, that a real duel enſued; and the appointment being on horſeback with piſtols, to put him more on a level, Jeffery, with the firſt fire, ſhot his antagoniſt dead. This happened in France, whither he had attended his miſtreſs in the troubles. He was again taken priſoner by a Turkiſh rover, and ſold in Barbary. In 1644, he attended the queen to France, where he remained till the Reſtoration. At laſt, upon ſuſpicion of his being privy to the Popiſh plot, he was taken up in 1682, and confined in the Gatehouſe, Weſtminſter, where he ended his life, in the 63d year of his age.

In the Philoſophical Tranſactions we have well authenticated accounts of two dwarfs: one born in Norfolk, who, at the age of twenty-two, weighed no more than thirty-four pounds with all his cloaths on, and whoſe height, including hat, wig, and ſhoes, was only thirty-eight inches; and another in Wales, who, at the age of fifteen, meaſured no more than two feet ſeven inches, and weighed only 13 pounds; and who at that early period of life laboured under all the infirmities and calamities of very old age. Phil. Tranſ. vol. xlvi. p. 67, and vol. xlvii. p. 279.

Dwarf *Trees*, a ſort of diminutive fruit trees, frequently planted in the borders of gardens; thus called from the lowneſs of their ſtature.

Dwarf trees were formerly very much in requeſt in gardens; but ſince the introducing of eſpaliers, they are much neglected. The manner however of propagating dwarf pears, which have been found to ſucceed the beſt of any dwarfs, is this: they are to be grafted a quince ſtock, and that at about ſix inches above the ground; and when the bud has ſhot ſo far as to have four eyes, it is to be ſtopped, to give riſe to lateral branches. Two years after the budding, the trees will be fit to tranſplant to the ſpot where they muſt remain. They ſhould be ſet at five and twenty, or thirty feet ſquare diſtance, and the ground between may be ſown or planted for kitchen uſe, while the trees are young, only obſerving not to plant too near their roots. There ſhould be ſtakes driven down all round the tree, to which the branches muſt be nailed with liſt, while they are young, training them into an horizontal direction, and no branches are to be ſuffered afterwards to croſs one another, and in ſhortening the ſhoots, the uppermoſt eye muſt always be left outwards. The ſummer and autumn pears are thoſe which do beſt in dwarfs, for the winter ones never ſucceed well on them.

Apples are alſo ſometimes planted as dwarfs, and are for this purpoſe moſt commonly grafted on paradiſe ſtocks. Theſe ſpread much leſs than the pears, and therefore need only be ſet at about eight feet diſtance. Some alſo plant apricots and plums for dwarfs; but theſe being of a more tender conſtitution, ſeldom ſucceed well. Miller.

DYEING, in the utmoſt latitude of the word, may be defined, the art of tingeing cloth, ſtuff, or other matter, with a permanent colour, which penetrates the ſubſtance thereof. It is, however, commonly reſtrained to the art of tingeing ſilk, wool, cotton, and linen, with different colours; and, as ſuch, is practiſed as a trade by thoſe who do not meddle with any of the other branches, as ſtaining of leather, &c.

TREATISE ON DYEING.

Antiquities of the Art.

THE dyeing art is of great antiquity; as appears from the traces of it in the oldeſt ſacred, as well as profane writers. The honour of the invention is attributed to the Tyrians; though what leſſens the merit of it is, that it is ſaid to have owed its riſe to chance.

The juices of certain fruits, leaves, &c. accidentally cruſhed, are ſuppoſed to have furniſhed the firſt hint: Pliny aſſures us, that even in his time the Gauls made uſe of no other dyes: it is added, that coloured earths, and minerals, waſhed and ſoaked with rain, gave the next dyeing materials. But purple, an animal juice, found in a ſhell fiſh called murex, conchylium, and purpura, ſeems from hiſtory to have been prior to any of them. This indeed was reſerved for the uſe of kings and princes; private perſons were forbidden by law to wear the leaſt ſcrap of it. The diſcovery of its tingeing quality is ſaid to have been taken from a dog, which having caught one of the purple fiſhes among the rocks, and eaten it up, ſtained his mouth and beard with the precious liquor; which ſtruck the fancy of a Tyrian nymph ſo ſtrongly, that ſhe refuſed her lover Hercules any favours till he had brought her a mantle of the fine colour.

Pliny ſeems to aſcribe the invention of the art of dyeing wool to the Lydians of Sardis: "*Inficere lanas Sardibus Lydi*;" where the word *incipere* muſt be underſtood. But a modern critic ſuſpects a falſe reading here; and, not without reaſon, for *Lydi*, ſubſtitutes *Lydda*, the name of a city on the coaſt of Phœnicia, where the chief mart of the purple dye was.

After the Phœnicians, the Sardinians ſeem to have arrived at the greateſt perfection in the dyeing art; inſomuch, that *βαμμα Σαρδινιακον, Sardinian dye*, paſſed into a proverb among the Greeks. Till the time of Alexander, we find no other ſort of dye in uſe among the Greeks but purple and ſcarlet. It was under the ſucceſſors of that monarch, that theſe people applied themſelves to the other colours; and invented, or at leaſt perfected, blue, yellow, green, &c. For the ancient purple, it has been long loſt; but the perfection to which the moderns have carried the other colours, abundantly indemnifies them of the loſs. It is ſtill, however, greatly to be doubted whether the permanency of the modern colours at all equals that of the ancient ones; though it is certain, that the former greatly exceed them in brightneſs.

SECT. I. THEORY OF DYEING.

Salts the only Means of fixing Colours.

Before we can enter into any conſideration of the true theory of dyeing, it is neceſſary to make the following obſervation concerning the practice, namely, The ſalts are almoſt the only means we are acquainted with by which any colouring ſubſtance can be made to fix itſelf upon thoſe matters which are the common ſubjects of dyeing. A ſolution of cochineal, for inſtance, will of itſelf impart no permanent colour to a piece of woollen cloth put into it. The red colour of the cochineal will indeed ſtain the cloth while it remains immerſed in the ſolution; but as ſoon as it is taken out and waſhed, this temporary ſtain will immediately vaniſh, and the cloth become as white as before. If now the cloth is dipped in the ſolution of any ſaline ſubſtance, alkalies alone excepted, and then immerſed in the ſolution of cochineal for ſome time, it will come out permanently coloured; nor will the colour be diſcharged even by waſhing with ſoap and water. If a quantity of ſalt is added to the ſolution of cochineal, and the cloth put in without being impregnated with any ſaline ſubſtance, the effect will be the ſame; the cloth will come out coloured; only in this laſt caſe, it muſt be well dried before waſhing it with ſoap, or moſt of the colour will be diſcharged.

They operate by Coagulation.

A ſaline ſubſtance, (ſolution of tin in aqua regia), has a ſurpriſing power of coagulating the colouring matter of certain ſolutions, ſuch as cochineal, Brazil wood, logwood, &c. If therefore a piece of cloth is previouſly impregnated with this ſolution, and put into the colouring one, it is plain that ſome part of the colouring matter will be coagulated by the ſolution remaining in the cloth, in the very ſame manner that it would have been if a ſmall quantity of the ſaline ſolution had been poured into the other. The cloth therefore will take up a part of the colouring matter, which cannot be diſcharged but by entirely diſcharging the ſolution of tin. This, however, ſeems to unite itſelf with the cloth very firmly, ſo that ſcarce a particle of colour will be diſcharged by waſhing in plain water, or even with ſoap; nor can the whole be taken out, without boiling the cloth in a ſolution of fixed alkali.

Though ſolution of tin produces this coagulation in the moſt remarkable manner, it is not to be doubted that the ſame power is poſſeſt in ſome degree by moſt of the neutrals and imperfect ſalts. Alum poſſeſſes it very conſiderably, though not ſo much as ſolution of tin; and hence that ſalt is very much uſed in dyeing, as well as ſugar of lead, which alſo has a very ſtrong power of coagulation. The proceſs of dyeing, therefore, ſeems to be moſt analogous to that of the coagulation or curdling of milk. Before it has ſuffered this change, the milk is eaſily miſcible with water; but after it is once coagulated, the curd, or caſeous part, is very difficultly ſoluble in any liquid whatever. In like manner, the colouring matter in the ſolution of cochineal, before the cloth is put in, is eaſily ſoluble in water, and may be diffuſed through any quantity of fluid: but no ſooner is the cloth dipped in it, than the ſaline ſubſtance contained in the cloth coagulates that part of the colouring matter which lies in immediate contact with it; and, as all the fluid ſucceſſively comes into contact with it, the whole of the colour is by degrees coagulated and depoſited on the cloth.

Hypotheſes concerning the Adheſion of the Colour.

To account for the ſtrong adheſion of the colour to the dyed cloth, ſeveral hypotheſes have been formed. One is, That the fibres of wool, ſilk, &c. are hollow tubes; that the colouring matter enters them; and, after being there coagulated, ſhews itſelf through the fine tranſparent ſides of the tubes. Another conſiders theſe filaments as ſolid lengthwiſe, but having all round their ſides an infinite number of ſmall pores like the extremities of the fine abſorbing and exhaling veſſels of the human body. In theſe pores, according to the hypotheſis, the colour is lodged; and as the pores are placed exceedingly cloſe to one another, the fine threads appear to our eyes of one uniform colour. A third is, That the fibres are ſolid, or at leaſt with reſpect to us may be conſidered as ſuch. The ſaline ſubſtance, whatever it is, that is employed to make the colour ſtrike, ſinks into the ſurface, partly corrodes and unites itſelf with it into a third kind of ſubſtance no longer ſoluble in plain water, nor even eaſily by ſoap, but which ſtill preſerves its coagulating quality. According to this hypotheſis, the dye lies entirely on the out ſide of the ſtuff, and continues as long as the effect of the ſalt continues upon the fibres of the matter to be dyed.

Concerning the truth of theſe hypotheſes, or indeed any others that can be invented, it is impoſſible to bring any deciſive proof. It ſeems, however, more probable that the proceſs of dyeing is accompliſhed by a coagulation of the colouring matter itſelf, rather than by any agglutination of it to the fibres by means of a vitriolated tartar, as Mr. Hellot ſuppoſes.

Mr. Hellot's Hypotheſis diſproved.

According to this gentleman's theory, a vitriolated tartar is generated in every proceſs for dyeing, and proceeds from the acid of the alum and alkaline baſis of the tartar uſed in the preparations, or in ſome of the dyeing ingredients themſelves. He ſuppoſes that the pores of the ſtuff are cleanſed and enlarged by the preparatory ſalts, and by the boiling water, in ſuch a manner as to receive the colouring particles, which particles are afterwards detained by the contraction of the pores occaſioned by cold; and further, that theſe pores are lined with a ſaline cruſt of tartar or vitriolated tartar.

On this theory, the tranſlator of the Chymical Dictionary has the following obſervations. "Mr. Hellot has not ſhown that pure fixed alkali is incapable of producing the effects which he attributes to his tartar and vitriolated tartar; and both theſe ſalts, though they are difficult of ſolution, and require a great quantity of water for this purpoſe, will yet diſſolve at laſt; and therefore, if the colouring particles were fixed chiefly by means of theſe ſalts, they might be waſhed out by a large quantity of water.

Another Hypotheſis.

"We ſhall find it more difficult to ſubſtitute a true theory, than to refute that of Mr. Hellot. Many experiments ought to be previouſly made. Nevertheleſs it may be obſerved, That the colorific particles of moſt ſubſtances uſed in dyeing ſeem to be inſoluble in water, in ſpirit of wine, and even in alkaline lixiviums; that their diffuſion through theſe liquids is cauſed merely by their adheſion to certain gummous and reſinous particles: and that they may be diſengaged from thoſe gummy and reſinous matters, by applying a piece of ſtuff to which they have a greater adheſive power, which ſeems to be the caſe of the root coloured and blue dyes; or by applying another ſubſtance to which theſe particles have a greater power of adheſion; ſuch as the earth of alum, in thoſe dyes where that ſalt is uſed, together with ſome other ſubſtance, as fixed or volatile alkali, capable of decompoſing alum; or as the ferruginous earth of the green vitriol in black dyes, to which the colorific particles of the galls adhere; which earths are capable of applying themſelves and of adhering to the ſtuffs. The ſeparation of the colouring particles from the gummy and reſinous matters is probably facilitated by the addition of acids and neutral ſalts, which may coagulate in ſome meaſure the vegetable matters, and leave the colorific particles diſengaged; ſo that they may apply themſelves to the ſtuff, or to the earths above mentioned."

But, in whatever way the ſalts uſed in dyeing do act, it is certain they are capable, except in a very few inſtances, of fixing and giving a luſtre and permanency to the colour, which otherwiſe could never be obtained.

Exceptions to the General Rule.

The exception to this general rule moſt commonly known, is that of indigo. This is a fine blue fecula produced by fermentation from the leaves of the Indian plant called *anil*. It is very difficult of ſolution; however it may be diſſolved by alkaline ſalts, concentrated oil of vitriol, orpiment, or combinations of ſulphur with quicklime. If a quantity of indigo is diſſolved in a fixed alkali, (for volatile alkalies will not diſſolve it), the ſolution is always green, which is the natural colour, produced in all vegetable blues by the alkali: but if any piece of ſtuff is put into this ſolution, though it remains while immerſed in the liquid, the moment it comes in contact with the air, the diſſolving power of the alkali is totally deſtroyed; the indigo is precipitated upon the cloth, reſumes its native colour, and dyes the cloth blue.

The cauſe of this precipitation is very difficult to be inveſtigated. Perhaps it may be owing to an attraction of fixed air by the alkali from the atmoſphere, which renders the ſalt unable to diſſolve the indigo any longer. The adheſion of the colour ſeems merely owing to an attraction between it and the cloth; for the alkaline ſalt can contribute nothing to this, but would rather have the contrary effect. Perhaps, however, the great ſolvent power poſſeſſed by alkaline ſalts, by perfectly clearing away every kind of ſordes, may bring the indigo and cloth into nearer contact with each other, than when it is diſſolved in any other way; and conſequently the attraction will in theſe caſes be the ſtronger. This ſeems to have ſome probability; for when indigo is diſſolved in vitriolic acid, as in dyeing Saxon blue, the colour is much more eaſily diſcharged.

Another exception is in the juices of ſome vegetables, ſuch as the nuts of the anacardium. This produces, without addition, a moſt deep and laſting black, never to be waſhed out or diſcharged by any means whatever. Several other plants are to be found in different parts of the world, which give an indelible black ſtain upon linen without addition; and the colouring matter of theſe ſeems to adhere by means of a very tenacious gluten, with which it is mixed, and which, when once thoroughly dried, can never be again diſſolved. In this reſpect, theſe black ſtaining colours ſeem analogous to the *purpura* of the ancients; which ſtained indelibly without addition, and was of an exceedingly viſcous and adheſive nature.

SECT. II. PRACTICE OF DYEING.

Of the colouring Materials, and Ingredients for fixing the Colours.

True and falſe Dyes.—The materials for dyeing different colours are ſo many and various, that an enumeration of them all is ſcarce to be expected. Some ingredients produce durable colours, which cannot be diſcharged either by expoſure to the air, or by waſhing with ſoap: others, though they may be made to ſtand the action of ſoap pretty well, cannot by any means be enabled to reſiſt the action of the air. Theſe are diſtinguiſhed by the different names of *true* and *falſe*, *permanent* and *fading*, &c. nor is there any method yet diſcovered of giving the falſe colours an equal degree of durability with the true ones. This hath been attempted by mixing a permanent and a fading colour together; in which caſe it was thought that the former would impart ſomewhat of its durability to the latter: but this hath always been found to miſgive; the fading colour ſoon flying off, and leaving the permanent one behind. The ſame hath alſo been attempted by dyeing a piece of ſtuff partially with a fading colour, and then completing the dye with a permanent one. In this caſe, it was hoped that the fading colour being covered over, and defended from the injuries of the air, by the permanent one, would neceſſarily become equally durable, or at leaſt remain a much longer time than if the ſtuff was dyed with it alone. But this alſo hath been found ineffectual; and the fading colour hath been diſſipated as ſoon when covered with a permanent one, as when left without any ſuch cover. Solution of tin in aqua regia will give moſt of theſe fading colours an high degree of beauty, and ſome ſhare of durability, though even that is not able to make them equal to the others. The moſt permanent dyes we have are cochineal and gum lac for fine reds and ſcarlets; indigo and woad for blue; and when mixed in different proportions with cochineal, or lac, for purple and violet colours. Weld, and ſome other vegetables, for yellow; and madder for coarſe reds, purples, and blacks. The fading colours are much more numerous. In this claſs are included brazil-wood, log-wood, peach-wood, red-wood, fuſtic, turmeric root, annotto, archil, &c. &c.

Salts to be uſed in Dyeing.

With regard to the ſalts made uſe of in dyeing, it hath been but too often cuſtomary to jumble together ſuch a quantity of different ones, that it was not only impoſſible to know in what particular ſalt the virtue reſided, but often the efficacy of the whole hath been totally deſtroyed, and the colour entirely ſpoiled by ſuch injudicious management. It is proper, therefore, where a mixture of two or more ſalts is intended to be made for dyeing, firſt to try the change of colour produced by each of the ſalts upon the colouring ſubſtance. If the colours are nearly alike, the mixture may be ſafely made as to that particular. But if the two colours produced by the different ſalts are very different from one another, to mix them together muſt be very injudicious. Thus, ſuppoſe you want to dye ſcarlet, ſolution of tin in aqua regia produces the neceſſary change of colour on the decoction of cochineal, and converts it into a high flame colour, which ſhews it to be a proper ingredient; but, to the ſolution of tin, it would ſurely be the greateſt abſurdity to add a quantity of ſaccharum ſaturni, the effect of which is to change the colour of cochineal to a dull purple. But, though the ſalts taken ſeparately ſhould produce a colour nearly ſimilar, another thing muſt be regarded, namely, whether they can be mixed with ſafety to one another. It is the nature of many ſalts to deſtroy one another whenever they come into perfect contact by being diſſolved in water. Thus, ſolution of tin and ſaccharum ſaturni deſtroy one another; and ſo do ſolution of tin, and tartar, or cream of tartar. To mix theſe together muſt therefore be abſurd; and yet we find this laſt mixture ordered in almoſt every receipt for dyeing ſcarlet. It is alſo to be obſerved, that a mixture of different ſalts ought never to be made, out of a notion that the colour will keep the better on that account; for moſt commonly it will keep the worſe. A ſingle ſalt will anſwer for this purpoſe, better than a hundred. A mixture ſhould only be made where it is neceſſary to produce the colour deſired; and if a dyer proceeds in this ſimple manner, he may not only attain to great perfection in the art from his own experience without being taught by others, but even make conſiderable diſcoveries; as dyeing is at preſent far enough from being brought to perfection.—The ſalts chiefly to be uſed in dyeing are fixed alkalies; ſolutions of tin in the vitriolic and marine acids, and in aqua regia; ſugar of lead; cream of tartar; alum; oil of vitriol; and ſolution of iron in the acetous acid. By means of theſe, almoſt all kinds of colours may be dyed at an eaſy rate, and with very little trouble.

Of the Manner of uſing the Ingredients, and of producing the different Colours.

As the art of dyeing is, by the principles above laid down, reduced to a great degree of ſimplicity, almoſt all the directions for the practice will be contained in the following general rule.

General Rule for Dyeing all Colours.

Having cleaned the ſubſtance to be dyed as well as poſſible, and made choice of the ſalt proper for producing the colour deſired, diſſolve the ſalt in water, and ſteep the ſubſtance in that ſolution for 24 hours. Then take it out; and, without wringing, hang it up to dry, but without heat: and for this it will be proper to allow a pretty long time; for the more perfectly the ſalt penetrates the cloth, the more durable will the colour be. Having then prepared a coloured ſolution or decoction, put the cloth into it. The leſs heat that is applied during the time the cloth remains in the dye, the finer the colour will be, but the longer time will be required for completing the operation. If time cannot be ſpared, ſo that a ſtrong heat muſt be applied, it will be neceſſary to roll the the cloth during the time of dyeing, or the colour will be in danger of proving unequal. After the dyeing is completed, rinſe the cloth in cold water, but do not wring it ſeverely; and then hang it up to dry.

In this way may be dyed a great variety of colours, on wool, ſilk, cotton, and linen, without any variation in the proceſs. Solution of tin in the vitriolic acid will produce all degrees of red, from the paleſt pink or roſe colour, to the higheſt crimſon and ſcarlet; and that on all the abovementioned ſubſtances without exception.

Method of Dyeing Cotton and Linen Scarlet.

A method of producing theſe fine colours upon cotton and linen, as well as wool, hath been a great deſideratum in dyeing; but by the abovementioned ſolution theſe ſubſtances may be dyed of the moſt beautiful red, crimſon, and ſcarlet colours, as any one may very readily ſatisfy himſelf by a trial. The ſame thing may be done by ſolution of tin in aqua regia; but unleſs the nitrous acid prevails greatly in the mixture, the colours produced by this laſt will incline more to the purple than the former. With ſolution of tin in the marine acid, they incline remarkably to purple, and are likewiſe deficient in luſtre. The two firſt ſolutions therefore are capital ingredients in dyeing red.

Various other Colours.

The ſame preparations will alſo ſerve for dyeing all other colours, blue and green excepted. Thus, a piece of cloth prepared with ſolution of tin in the vitriolic acid, if boiled in a decoction of cochineal, will come out of a ſcarlet colour; if with turmeric, weld, fuſtic, or many of the common yellow flowers, it will come out of different degrees of yellow; with Brazil wood, peach wood, &c. it will give a fine purpliſh crimſon; with logwood, a fine deep purple, &c. and by combining theſe together in different ways, an infinity of different ſhades may be produced.

Directions for the Coarſer Colours.

For the coarſe reds produced from madder, the ſolutions of tin are not found to anſwer. The proper ſalts for theſe are alum and cream of tartar. In dyeing with madder, it is always neceſſary, more than when any other ingredient is uſed, to let the heat be gentle; becauſe the root, beſides the red colour it contains, has alſo a great quantity of browniſh matter in it, which is extracted by ſtrong boiling, and debaſes every colour with which it is mixed. Sugar of lead produces a purple with this root; which, however, will be brightened by an addition of alum and ſal ammoniac. A dark purple may alſo be produced from madder by mixing alum with a little ſolution of iron in the vegetable acids, particularly the acetous. With regard to blue colours, they are only to be dyed by means of indigo. This ſubſtance may be diſſolved, as we have already obſerved, by alkaline ſalts, concentrated acids, and orpiment. The firſt of theſe produces the common blues; the ſecond, the Saxon blue; and the third, the blue which is uſed in callico printing. The method of dyeing the common blue requires only the ſtuff to be dipped in a ſolution of indigo in the alkaline ſalt; and if the liquor is hot, the dyeing will be over almoſt inſtantaneouſly. For cotton and linen, another method hath been uſed. Lime is added to the pot aſh, and the ſtrength of the alkali being by this means increaſed, the indigo is very ſoon diſſolved. Some raiſins are now to be beat in a braſs or marble mortar to a pulp, and thrown into the ſolution of the indigo as ſoon as taken off the fire. It ſoon throws up a copper coloured ſcum to the ſurface; and the cotton being now put into the liquor receives the colour in an inſtant. This is a very beautiful blue; but in what manner the raiſins act, is a matter which yet remains to be determined. If a piece of cloth is dipped in a ſolution of copper in the nitrous acid, and then boiled in logwood, it will come out of a purpliſh blue colour. This dye, however, has very little beauty or durability, and is therefore ſcarce worthy of notice.

Common green vitriol or copperas is thought to improve blue colours in general: but on what foundation, is not very apparent. By means of it, however, the colour of Pruſſian blue may be ſtruck upon cloth in ſuch a manner as to produce a temporary ſtain of exceeding great beauty; and could any method of fixing this colour be fallen upon, it would undoubtedly be a moſt valuable acquiſition. The method is, to digeſt ſome Pruſſian blue in fixed alkali till the colour is extracted. In this ſolution dip the cloth intended to be dyed, and dry it; then let it lie for a little time in a weak ſolution of copperas, and it will immediately become of a moſt beautiful blue colour. This colour, however, is diſcharged by waſhing with ſoap, and even with ſimple water.

Mr. Woulfe's Receipt for Saxon Blues.

A receipt was publiſhed by Mr. Woulfe, in the philoſophical tranſactions, for an improved method of dyeing the Saxon blue; which is done by diſſolving indigo in concentrated oil of vitriol. The only improvement in Mr. Woulfe's proceſs, conſiſted in digeſting the oil of vitriol and indigo in the heat of boiling water inſtead of a ſand-heat, becauſe the latter was often found to ſpoil the colour. After the indigo is diſſolved, the ſolution may be weakened at pleaſure with water; and any piece of ſtuff then dipped in it will imbibe the colour, in proportion to the ſtrength of the ſolution. This dye is very beautiful; but will neither keep its colour, nor ſtand waſhing with ſoap: unleſs great care is taken, it is alſo very apt to prove unequal.

Green colours are to be produced only by a mixture of blue and yellow; for there is no ingredient yet diſcovered, that will, by itſelf, give a good green dye. Sap-green will indeed communicate its own colour to cloth of any kind, and for that purpoſe is uſed in ſome places; but the colours dyed with this ingredient are by no means eligible. It is common firſt to dye the cloth blue with indigo, and then yellow with any yellow colouring ingredient; by which means a green colour is produced. For the dying of Saxon green, however, it is neceſſary to produce a particular kind of yellow from indigo. This is obtained by diſſolving indigo in ſpirit of nitre. Mr. Woulfe recommends an ounce and an half of powdered indigo to be mixed with two ounces of ſpirit of nitre diluted with four times its quantity of water. The mixture is then to ſtand for a week; and, at the end of that ſpace, muſt be digeſted in a ſand heat for an hour or more; after which, four ounces more of water is to be added: the ſolution, when filtered, will be of a fine yellow colour. Strong ſpirit of nitre is apt to ſet fire to indigo; for which reaſon, as well as to hinder the mixture from frothing up, it muſt be diluted with water. Two ounces and an half of ſtrong ſpirit of nitre will ſet fire to one ounce and an half of indigo; but if the acid is highly concentrated, a leſs quantity will ſerve.

If the indigo be digeſted 24 hours after the ſpirit of nitre is poured on it, it will froth and boil over; but, after ſtanding a week or leſs, it has not that property.

One part of the ſolution of indigo in the acid of nitre, mixed with four or five parts of water, will dye ſilk or cloth of the paleſt yellow colour, or of any ſhade to the deepeſt, and that by letting them boil more or leſs in the colour. The addition of alum is uſeful, as it makes the colour more laſting. According as the ſolution boils away, more water muſt be added.

None of the colour in the operation ſeparates from the water, but what adheres to the ſilk or cloth; of conſequence, this colour goes far in dyeing.

Cochineal, Dutch litmus, archil, cudbear, and many other colouring ſubſtances, treated in this manner, will all dye ſilk and wool of a yellow colour.

The indigo which remains undiſſolved in making Saxon blue, and collected by filtration, if digeſted with ſpirit of nitre, dyes ſilk and wool of all ſhades of brown inclining to a yellow.

Cloth and ſilk may be dyed green with indigo; but they muſt firſt be boiled in the yellow dye, and then in the blue.

Black Colours dyed.

Black colours are dyed by preparing the cloth with any ſolution of iron, (but that in the acetous acid is beſt,) and then boiling it in a decoction of any aſtringent vegetable. Thoſe chiefly made uſe of for the purpoſes of dyeing, are galls, ſumach, logwood, and madder. Of theſe the laſt is the moſt durable; though galls will alſo produce a very pretty laſting colour, if properly managed. Logwood dyes a very pretty, but fading, black colour. It appears, however, from ſome experiments made by Mr. Clegg, that, by a proper preparation of the cloth with fixed alkaline ſalts, black colours dyed with logwood might be improved both as to beauty and durability; we ſhall therefore introduce his remarks on the ſubject contained in Percival's Eſſays, vol. 3. page 335. "I took (ſays he) two veſſels, containing equal meaſures of a ſtrong aſtringent liquor, compoſed of galls and logwood: into one veſſel I put a ſmall quantity of pearl aſhes; the other remained as a ſtandard. Pieces of linen and cotton cloth, after maceration in theſe liquors, were thrown together into a ſtrong ſolution of copperas; they were ſoon after taken out, and waſhed in cold water. When dry, the pieces prepared in aſhes were, all of them, much deeper than the others.

I made uſe of different kinds of pearl and pot aſhes, as well as many kinds of aſtringents: the aſhes had the ſame effect whatever aſtringent was made uſe of, and the ſtrongeſt alkali always produced the deepeſt colour; and though aſhes, uſed with an aſtringent, always gave a deeper colour than the ſame aſtringent without aſhes, yet logwood, which without aſhes gave not ſo deep a colour as galls with them, gave a much deeper black than galls with the ſame addition.

"There was a remarkable difference in this caſe between lime and aſhes in their effect upon logwood; with lime it gave no blackneſs, but with aſhes it produced a deeper black than any other aſtringent I made uſe of.

"Being deſirous of trying the duration of colours produced by aſtringents, in which different quantities of pearl aſhes had been diſſolved; in two pints of river water I boiled one ounce of logwood during ten minuets; I then added half an ounce of Aleppo galls, and boiled them together ten minuets longer; the liquor having ſtood to cool, was decanted off, and divided into ſix equal quantities. N° 1, remained as a ſtandard; into N° 2, I put ſix grains of fine pearl aſhes; N° 3, twelve grains; N° 4, eighteen grains; N° 5, twenty four grains; N° 6, thirty grains. To ſix drops of each of theſe liquors, I added two drops of a ſaturated ſolution of copperas. N° 2 and 3, ſtruck a deep black; N° 1 and 4, black, but inferior to 2 and 3; N° 5, a brown black; N° 6, brown.

"From this experiment it appears, that N° 5 and 6, were ſpoiled by an over proportion of aſhes. All theſe colours were tried by writing with them on paper, and the writings have now been expoſed ſix months to the air. In N° 5 and 6, the blackneſs is quite deſtroyed; N° 4 is ſomething faded: N° 1, 2, 3, remain nearly as they were, N° 2 and 3, being ſtill ſuperior to the ſtandard."

The fineſt blacks are firſt dyed blue, with indigo; and afterwards black with ſolution of iron, and ſome aſtringent vegetable, according to the directions already given.

Theſe are the beſt methods for producing permanent colours of all kinds. As it is neceſſary, however, often to give another colour to ſtuffs which have been already dyed, it is plain, that it is as neceſſary for a dyer to know how to diſcharge colours, as how to make the cloth imbibe them.

How to diſcharge Colours when dyed.

Concerning this, it is only neceſſary to obſerve, that alkaline ſalts are in general the beſt, and, where the colours are well dyed, the only means of diſcharging them. If a piece of cloth is dyed with logwood, and the colour ſtruck upon it with alum, that colour will be nearly diſcharged by oil of vitriol, or any other ſtrong acid; but if ſolution of tin has been employed in ſtriking the colour, acids have then no effect, and alkalies only can be employed. Neither will they diſcharge the colour totally, but the ſtuff muſt be bleached for ſome time to get out the remainder. If alkaline ſalts cannot be employed with ſafety to the ſtuff, it is then impoſſible to dye it any other colour than black; unleſs it be dyed a compound colour, of which the original one is a component part.

Of the Increaſe of Weight in Dyeing.

Concerning the weight that colours give to ſilk, (in which it is moſt taken notice of, being ſold by weight, and a commodity of great price), it is obſerved, that one pound of raw ſilk loſeth four ounces by waſhing out the gums and the natural ſordes; that the ſame ſcoured ſilk may be raiſed to above thirty ounces from the remaining twelve, if it be dyed black with ſome materials. Of all the materials uſed in dyeing, eſpecially of black, nothing increaſes weight ſo much as galls, by which black ſilks are reſtored to as much weight as they loſt by waſhing out their gum: nor is it counted extraordinary, that blacks ſhould gain about four or ſix ounces in the dyeing upon each pound. Next to the galls, old fuſtic increaſes the weight about $1\frac{1}{2}$ in 12; madder, an ounce; weſd half an ounce. The blue vats in deep blues of the fifth ſtall, give no conſiderable weight; neither do logwood, cochineal, nor even copperas, where galls are not.

Dyeing *of Thread* is begun by ſcouring it in a ley of good aſhes; after which, it is wrung, rinſed out in river water, and wrung again. For a bright blue, it is given with braziletto and indigo. Bright green is firſt dyed blue, then back-boiled with braziletto, and verditer, and laſtly woaded. For a dark green, it is given like the former, only darkening more before woading. Lemon, or pale yellow, is given with weld, mixt with rocou. Orange and Iſabella, with fuſtic, weld, and rocou. Red, both bright and dark, with flame-colour, &c. are given with brazil, either alone, or with a mixture of rocou. Violet, dry roſe, and amaranth, are given with brazil, taken down with indigo. Feuelmort and olive colour are given with galls and copperas, taken down with weld, rocou, or fuſtic. Black is given with galls and copperas, taken down and finiſhed with braziletto wood.

It is obſervable, that the black vitriolic dye, which is very durable on the ſubſtances already mentioned, is periſhable on linen and cotton. Pieces of both ſorts of cloth and ſkains of thread boiled firſt with gall, and afterwards infuſed and dipped repeatedly in a decoction of logwood with vitriol, received a good black colour, which was in ſome meaſure diſcharged by waſhing with ſoap; and the black dye proved equally periſhable, though the linen was ſteeped for a month previous to the dye, with galls and with oak bark. The dyers of thread obtain a colour ſomewhat more laſting, by ſteeping it firſt in alum water for ſeveral days, and then dipping it repeatedly in the dyeing liquor, cold, or only lukewarm. This liquor conſiſts of the irony and aſtringent matters mixed together; and in the room of, or along with vitriol, they uſe either filings of iron or ſlippe. Dr. Lewis made ſeveral unſucceſsful trials to fix the black dye in linen and cotton. He has given us, from the diſſertation of M. l'Abbé Mazeas, on the red printed cottons of the Eaſt Indies, an account of a method practiſed by the Indians, of impregnating their cotton with an animal matter, in order to its receiving a red ſtain.

A ley is made from the aſhes of a certain kind of wood, and with this is mixed ſome ſheep's dung, and a quantity of the oil of ſeſamum, in want of which oil they uſe hog's lard: theſe ingredients ſtirred together are ſaid to unite into a milky liquid. The cotton is ſteeped in this liquid during the night, and expoſed to the hotteſt ſun during the day for a fortnight. He applied a ſimilar preparation to the black dye; but the reſult was not ſuch a degree of ſucceſs as to render the proceſs intereſting to the workman. He obſerves, on the credit of a ſkilful artiſt, that ſome printed linens and cottons have a durable black ſtain, which is made with madder and a ſolution of iron. For this purpoſe a quantity of iron is put into ſour ſtrong beer; and to promote the diſſolution of the metal the whole is occaſionally well ſtirred, the liquor at times drawn off, the ruſt beaten from the iron, and the liquor poured on again; the ſolution is not fit for uſe in leſs than a twelvemonth. This ſolution ſtains linens yellow, and of different ſhades of buff colour, and is the only known material by which theſe colours can be fixed on linen. The cloth, ſtained deep with the iron liquor, being afterwards boiled with madder, without any other addition, becomes of the dark colour which is ſeen on printed linens and cottons; which, though not a perfect black, bears a very near reſemblance to it. He apprehends, that a better black might thus be dyed on threads, than that which the printer on linen produces; becauſe in this laſt buſineſs, while ſome parts of the linen are ſtained deep with the iron liquor, in order to their being made black; others are ſtained paler, with the ſame liquor diluted with water, for making purple; and others, deſigned to be red, are prepared with a ſolution of alum and ſugar of lead; all theſe colours are dyed in the ſame copper of madder, with a heat a little below boiling; but a boiling heat, which would injure the red colour, would deepen the black, and might be advantageouſly applied, if thread, or whole pieces of linen or cotton, were to be dyed of this colour. Com. Phil. Techn. p. 429, &c.

Dyeing *of Hats*, is done by boiling a hundred pounds of logwood, twelve pounds of gum, and ſix pounds of galls, in a proper quantity of water for ſome hours; after which about ſix pounds of verdigris, and ten pounds of green vitriol are added, and the liquor kept ſimmering, or of a heat a little below boiling. Ten or twelve dozen of hats are immediately put in, each on its block, and kept down by croſs bars for about an hour and a half; they are then taken out and aired, and the ſame number of others put in their room; the two ſets of hats are then dipped and aired alternately, eight times each; the liquor being refreſhed each time with more of the ingredients, but in leſs quantity than at firſt. This proceſs affords a very good black on woollen and ſilk ſtuffs as well as on hats. Com. Phil. Techn. p. 428.

Dyeing *of Leather, Skins*, &c. A black colour is eaſily given to tanned leather, by rubbing it over three or four times with a ſolution of vitriol, or with a ſolution of iron in the vegetable acids. For leathers that have not been tanned, ſome galls or other aſtringents are added, to the ſolution of iron; and in many caſes, particularly for the finer parts of leather, and for renewing the blackneſs, ivory, or lamp-black are uſed. A blue colour is given by ſteeping the ſubject a day in urine and indigo, then boiling it with alum: or it may be given by tempering the indigo with red wine, and waſhing the ſkins therewith. Red is given by waſhing the ſkins, and laying them two hours in galls; then wringing them out; dipping them in a liquor made with liguſtrum, alum, and verdigris in water; and laſtly, in a dye made of brazil wood boiled with ley. Purple is given by wetting the ſkins with a ſolution of roch alum in warm water, and when dry again, rubbing them with the hand with a decoction of logwood in cold water. Green is given by ſmearing the ſkin with ſap-green and alum-water boiled; to darken the colour, a little more indigo may be added. Dark green is alſo given with ſteel-filings, and ſal ammoniac ſteeped in urine till ſoft, then ſmeared over the ſkin, which is to be dried in the ſhade. Sky-colour is given with indigo ſteeped in boiling water, and the next morning warmed and ſmeared over the ſkin. Yellow, by ſmearing the ſkin over with aloes and linſeed oil diſſolved and ſtrained: or by infuſing it in weld. Orange-colour is given by ſmearing with fuſtic berries boiled in alum-water; or for a deep orange, with turmeric. Salm. Polyg. lib. iii. cap. 34. p. 272. For the mode of preparing the leather for dyeing, See Currying.

Dyeing, *or Staining of Wood, for Inlaying, Veneering, &c.* Red, is done by boiling the wood in water and alum; then taken it out, adding brazil to the liquor, and giving the wood another boil in it. Black, by bruſhing it over with logwood boiled in vinegar, hot; then waſh it over with a decoction of galls and copperas till it be of the hue required. Any other colour may be given by ſqueezing out the moiſture of horſe-dung through a ſieve, mixing it with roch alum and gum arabic; and to the whole adding green, blue, or any other colour deſigned. After ſtanding two or three days, pear-tree, or other wood, cut to the thickneſs of half a crown, is put into the liquor boiling hot, and ſuffered to remain till it be ſufficiently coloured, Park. Treat. of Japan. cap. xxvii. p. 82.

Dyeing *of Bone, Horn, or Ivory*. Black is performed by ſteeping braſs in aqua fortis till it be turned green: with this the bone, &c. is to be waſhed once or twice: and then put in a decoction of logwood and water, warm. Green, is begun by boiling the bone, &c. in alum-water; then with verdigris, ſal ammoniac, and white wine vinegar; keeping it hot therein till ſufficiently green. Red, is begun with boiling it in alum-water, and finiſhed by decoction in a liquor compounded of quicklime ſteeped in rain-water, ſtrained, and to every pint an ounce of brazil wood added: the bone, &c. to be boiled herein till ſufficiently red. Other methods are given by Salmon. And from him by Houghton. Park. lib. cit. p. 83. Salm. Polygraph. lib. iii. cap. 35. p. 275. Hought. Collect. N° 138. tom. i. p. 361. See Horn, Ivory, &c. The refuſe of the Bow-dye given to hogs to feed on, is ſaid to tinge their very bones red.

DYNAMICS, from *δυναμις*, *power*, is the ſcience of moving powers; more particularly of the motion of bodies which mutually act on one another. See Syſtem of Mechanics.

DYNASTY, a term in hiſtory, ſignifying a race or ſucceſſion of kings of the ſame line, or family. The word is formed from the Greek, *δυναϛεια*, of *δυναϛευω*, *to be powerful, to be king*.

DYSCRASY, from *δυς* and *κρασις*, an ill temperament or habit of the blood and humours, as in a jaundice or the like.

DYSENTERY, *Δυσεντερια*, in medicine, a bloody diarrhœa; or a flux of blood by ſtool, attended with pains and griping. Dr. Akenſide calls this diſeaſe a rheumatiſm of the bowels.

The word *dyſentery* is formed from the Greek, *δυς*, *difficulty*, and *εντερον*, *inteſtine*, and properly ſignifies that kind of flux of the belly, characterized by the frequency of ſtools, or ejections, mixed with blood, and accompanied with gripes. The fever, ulcers, &c. which attend it, are not eſſential to the diſeaſe; though many, both of the ancients and moderns, think the latter are. See Syſtem of Medicine.

DYSOREXIA, from *δυς* and *ορεξις*, *appetite*, in medicine, a want of appetite, proceeding from an ill diſpoſition, or diminiſhed action of the ſtomach.

DYSPEPSY, *Δυσπεψια*, from *δυς* and *πεπτειν*, *coquere, to concoct*, in medicine, a difficulty or weakneſs of digeſtion. Bitters and ſubaſtringents are its proper remedy.

DYSPNOEA, *Δυσπνοια*, from *δυς* and *πνεω*, *I breathe*, in medicine, a difficulty of breathing, uſually called aſthma.

DYSURIA, *Δυσουρια*, from *δυς* and *ουρειν*, *to make urine*, in medicine, a difficulty of making urine, accompanied with pain, and a ſenſe of heat. It is called *ardor urinæ*, becauſe the urine ſeems to burn the urethra as it iſſues forth. The dyſuria differs chiefly from the ſtrangury in this, that in the ſtrangury the urine only ouſes out, as it were drop by drop; whereas in the dyſuria, when it is made, it ſtreams out without any interruption, and frequently in the proper quantity; thus it alſo differs from the iſchuria, which is a total ſuppreſſion of urine. The ordinary cauſes of the dyſuria are, the acrimony, or ſharpneſs of the urine, and this excoriation, or exulceration of the neck of the bladder, or of the urinary paſſage. The uſual remedies in this caſe are cooling laxatives and mucilaginous medicines, as gum arabic, diſſolved in barley-water; decoctions of marſhmallow-root, with or without nitre; camphor, and ſmall doſes of laudanum.

DYTISCUS, water-beetle, in entomology, a genus of inſects of the order of Coleoptera.

E, THE ſecond vowel, and fifth letter, of the alphabet. The letter E is moſt evidently derived from the old character Ǝ in the ancient Hebrew and Phœnician alphabets, inverted by the Greeks to this poſition E, and not from the Hebrew He ה. From the ſame origin is alſo derived the Saxon *e*, which is the firſt letter in their alphabet that differs from the Latin one. It is formed by a narrower opening of the larynx than the letter A; but the other parts of the mouth are uſed nearly in the ſame manner as in that letter.

It has a long and ſhort ſound in moſt languages. The ſhort ſound is audible in *bed*, *fret*, *den*, and other words ending in conſonants; its long ſound is produced by a final *e*, or an *e* at the end of words; as in *glebe*, *here*, *hire*, *ſcene*, *ſphere*, *interfere*, *revere*, *ſincere*, &c. in moſt of which it ſounds like *ee*; as alſo in ſome others by coming after *i*, as in *believe*, *chief*, *grief*, *reprieve*, &c. and ſometimes this long ſound is expreſſed by *ee*, as in *bleed*, *beer*, *creed*, &c. Sometimes the final *e* is ſilent, and only ſerves to lengthen the ſound of the preceding vowel, as in *rag*, *rage*, *ſtag*, *ſtage*, *hug*, *huge*, &c. The ſound of *e* is obſcure in the following words, *oxen*, *heaven*, *bounden*, *fire*, *maſſacre*, *maugre*, &c.

The Greeks have their long and ſhort *e*, which they call *epſilon* and *eta*. The French have at leaſt ſix kinds of *e*'s: the Latins have likewiſe a long and ſhort *e*; they alſo write *e* inſtead of *a*, as *dicem* for *dicam*, &c. and this is, no doubt, the reaſon why *a* is ſo often changed into *e*, in the preter tenſe, as, *ago*, *egi*; *facio*, *feci*, &c. As a numeral, E ſtands for 250, according to the verſe,

E, *quoque ducentos et quinquaginta tenebit.*

In muſic it denotes the tone *e-la-mi*. In the calendar it is the fifth of the dominical letters. And in ſea charts it diſtinguiſhes all the eaſterly points: thus, E alone denotes eaſt; and E. by S. and E by N. Eaſt by South, and Eaſt by North.

EAGLE, *Aquila*, in ornithology, according to Linnæus, a ſpecies of the 2d genus called falco, belonging to the firſt order accipitres or rapacious. It is alſo of the ſame genus and order in Latham's improved arrangement. See Plate I.

Its aery, or neſt, is uſually on the higheſt rocks, ſometimes on the tops of old trees. It feeds its young till ſuch time as they are able to fly, and then drives them out of the neſt.

Its food is birds, hares, lambs, kids, and fawns; nay, Sir Robert Sibbald aſſures us, children too, when it can catch them; of which he gives an inſtance in the Orcades iſlands. Prod. Nat. Hiſt. Scot. lib. iii. p. 2. and 14. The eagle frequently watches the fiſhing hawk, and as ſoon as it perceives it to have ſtruck a fiſh, takes wing, and purſues the bird till it lets fall its prey, and often catches it before it reaches the earth or water. Phil. Tranſ. N° 201. Eagles are remarkable for their longevity, and for their faculty of ſuſtaining a long abſence from food. Keyſler relates, that an eagle died at Vienna after a confinement of a hundred and four years, which juſtifies the alluſion of the Pſalmiſt. Pſalm. ciii. 5. Its ſight is quick, ſtrong, and piercing, to a proverb. Job xxxix. 29. The reaſon why the eagle, the fibres of whoſe optic nerves are not ſtronger than thoſe of other animals, is able to face the ſun, and endure its brighteſt rays, the Jeſuit Angelus, in his optics, aſſures us, is, that it has two ſets of eyelids, the one thick and cloſe, and the other thinner and finer, which laſt it draws over the eye, when it looks at any luminous body, and thus breaks the force of its rays.

Eagle, in heraldry, is accounted one of the moſt noble bearings in armoury; and, according to the learned in this ſcience, ought to be given to none but ſuch as greatly excel in the virtues of generoſity and courage, or for having done ſingular ſervices to their ſovereigns; in which caſes they may be allowed a whole eagle, or an eagle naiſſant, or only the head or other parts thereof, as may be moſt agreeable to their exploits.

The eagle has been borne, by way of enſign or ſtandard, by ſeveral nations. The firſt who ſeem to have aſſumed the eagle, are the Perſians; according to the teſtimony of Xenophon. Afterwards, it was taken by the Romans; who, after a great variety of ſtandards, at length fixed on the eagle, in the ſecond year of the conſulate of C. Marius: till that time, they uſed indifferently wolves, leopards, and eagles, according to the humour of the commander. The Roman eagles, it muſt be obſerved, were not painted on a cloth, or flag: but were figures in relievo, of ſilver or gold, borne on the tops of pikes; the wings being diſplayed, and frequently a thunder-bolt in their talons. Under the eagle on the pike, were piled bucklers, and ſometimes crowns. Thus much we learn from the medals.

Eagle, *Aquila*, in aſtronomy, a conſtellation of the northern hemiſphere. See Syſtem of Astronomy, Sect. VIII.

Black Eagle, an order of knighthood, inſtituted by the elector of Brandenburgh, in 1701, on his being crowned king of Pruſſia. The knights of this order wear an orange coloured ribband ſuſpending a black eagle.

White Eagle, a like order in Poland, inſtituted in 1325, by Uladiſlaus V. on occaſion of the marriage of his ſon Caſimir to the daughter of the great duke of Lithuania. The knights of this order wear a chain of gold, ſuſpending a ſilver eagle crowned.

EAGLET, a diminutive of eagle, properly ſignifying a young eagle. In heraldry, when there are ſeveral eagles on the ſame eſcutcheon, they are termed eaglets.

EAR, *Auris*, the organ of hearing; or that part whereby animals receive the impreſſion of ſounds. See Syſtem of Anatomy, Part VI. Sect. X. and Plate XI.

The comparative anatomy of the ear furniſhes abundant inſtances of the Creator's wiſdom. In birds, the outer ear is of a form proper for flight; not protuberant, as that would obſtruct their progreſs, but cloſe and covered. In quadrupeds, its form is agreeable to the poſture and motion of the body, but admirably varied, according to their various occaſions: in ſome, as the hare, it is large, open, and erect; by which means that timorous, defenceleſs creature is warned of the leaſt approach of danger: in others, it is covered, to keep out noxious bodies. In the ſubterraneous quadrupeds, who are forced to mine and dig for their food and habitation, as a protuberant ear would obſtruct them, and be liable to injuries, their ears are very ſhort, and are lodged deep, and backwards in the head.

Thus moles have no auricle at all, but only a round hole, between the neck and ſhoulder. Some authors obſerve, that this meatus, or paſſage, is cloſed with a little ſkin, which opens and ſhuts like an eyelid. The ſea-calf and the ſeveral ſpecies of lizards and ſerpents, are likewiſe without any external ear. And the tortoiſe, camelion, and generality of fiſhes, have the paſſage of the ear quite ſtopped, or covered over. And there is a ſort of whale, which has the aperture of the ear under the ſhoulder. See Comparative Anatomy.—Sect. II. for Birds.—Sect. I. for Quadrupeds.

The ear has its beauties, which a good painter ought by no means to diſregard; where it is well formed, it would be an injury to the head to be hidden.

By a ſtatute of Henry VIII. maliciouſly cutting off the ear of a perſon is made a treſpaſs, for which treble damages ſhall be recovered; and the offender is to pay a fine of ten pounds to the king. 37 Hen. VIII. cap. 6. § 4. In the index to the ſtatutes at large, it is ſaid, that this offence may be puniſhed as felony, by 22 and 23 Car. II. cap. 1. § 7. commonly called Coventry's Act; but ear is not mentioned in that ſtatute.

Ear, in muſic, denotes a kind of internal ſenſe, whereby we perceive and judge of harmony and muſical ſounds. See Music. In muſic we ſeem univerſally to acknowledge ſomething like a diſtinct ſenſe from the external one of hearing; and call it a good ear. And the like diſtinction we ſhould probably acknowledge in other affairs, had we got diſtinct names to denote theſe powers of perception by. Thus a greater capacity of perceiving the beauties of painting, architecture, &c. is called a fine taſte.

Ear *of Fiſhes*. All the cetaceous fiſhes have external meatus auditorii, or paſſages for hearing; but other fiſh have nothing of theſe external appearances, and ſeem neither to be intended by nature to make any ſounds, or to hear any. Though ſound being a tremulation in the air, it may be felt by them as motion, though not diſtinguiſhed as ſound. It may eaſily be proved, that they do not hear our voices in ſpeaking, by walking near the ſide of a pond or river well ſtored with fiſh about the hedges: if the body and its ſhadow be kept out of their ſight, they will never ſtart at the voice. Yet how far fiſhes are deaf and dumb, ſeems a queſtion not yet perfectly decided. See Comparative Anatomy, Sect. III.

Ear, in gardening, a name given to the ſeminal leaves of plants, or thoſe two green and ſucculent leaves which firſt appear from the ſeed, and are very different, in all reſpects, from thoſe which follow. Thus in the melon plants, the two firſt leaves are called ears; and the leaves, with their ſtalks, which ſhoot out afterwards, are called knots, and denominated the firſt, ſecond, and third knot, according to their place, and time of growing. The cutting off every third knot in this plant, is the great means of procuring the fineſt and largeſt fruit. Phil. Tranſ. N° 45.

Ear, in botany, is alſo applied to a long cluſter of flowers, or ſeeds, produced by certain plants; and uſually called, by botaniſts, ſpica. The flowers and ſeeds of wheat, rye, barley, &c. grow in ears. The ſame holds of the flowers of lavender, &c. We ſay, the ſtem of the ear, i. e. its tube, or ſtraw; the knot of the ear; the lobes, or cells, wherein the grains are encloſed; the beard of the ear, &c. great numbers of ears of wheat have been known to ariſe from the ſame root.

Ear *Pick*, an inſtrument of ivory, ſilver, or other metal, ſomewhat in form of a probe, for cleanſing the ear. The Chineſe have a variety of theſe inſtruments, with which they are mighty fond of tickling their ears; but this practice, Sir Hans Sloane obſerves, muſt be very prejudicial to ſo delicate an organ, by bringing too great a flow of humours on it.

Ear *Wig*, *forficula*, in entomology, the Engliſh name of a genus of inſects, of the order of coleoptera. For deſcription of the different ſpecies of this genus, ſee Forficula. For the Claſſification, ſee Syſtem of Entomology.

Ear *Shell*, *auris marina*, a genus of ſhell fiſh, called in the Linnæan diſtribution, *haliotis*. See ſyſtem of Conchology, genus 31.

EARED, in heraldry, when the ears of any bearing hath its ears of a different tincture, it is ſaid to be eared.

EARING, in a ſhip, that part of the bolt rope, which, at the four corners of the ſail, is left open, in the ſhape of a ring. The two uppermoſt parts are put over the ends of the yard arms, and ſo the ſail is made faſt to the yard; and into the lowermoſt earings the ſheet and tackles are ſeized, or bent at the clew.

EARL, a Britiſh title of nobility, next below a marquis, and above a viſcount. The title is ſo ancient, that its original cannot be clearly traced out. This much, however, ſeems tolerably certain, that among the Saxons they were called *ealdormen, quaſi* elder men, ſignifying the ſame with *ſenior* or *ſenator* among the Romans; and alſo *ſchiremen*, becauſe they had each of them the civil government of a ſeveral diviſion or ſhire. On the irruption of the Danes they changed their names to *eorles*, which, according to Cambden, ſignified the ſame in their language. In Latin they are called *comites*, (a title firſt uſed in the empire), from being the king's attendants; *a ſocietate nomen ſumpſerunt, regis enim tales ſibi aſſociant.* After the Norman conqueſt they were for ſome time called *counts* or *countees*, from the French; but they did not long retain that name themſelves, though their ſhires are from thence called counties to this day. It is now become a mere title: they have nothing to do with the government of the county; which is now entirely devolved on the ſheriff, the earl's deputy, or vicecomes. In writs, commiſſions, and other formal inſtruments, the king, when he mentions any peer of the degree of an earl, uſually ſtiles him "truſty and well beloved couſin:" an appellation as ancient as the reign of Henry IV; who being either by his wife, his mother, or his ſiſters, actually related or allied to every earl in the kingdom, artfully and conſtantly acknowledged that connexion in all his letters and other public acts: from whence the uſage has deſcended to his ſucceſſors, though the reaſon has long ago failed.

An earl is created by cincture of ſword, mantle of ſtate put upon him by the king himſelf, a cap and a coronet put upon his head, and a charter in his hand. All the earls of England are denominated from ſome ſhire, town, or place, except three; two of whom, viz. earl Rivers, and earl Paulet, take their denomination from illuſtrious families: the third is not only honorary as all the reſt, but alſo officiary, as the earl marſhal of England. See Syſtem of PEERAGE.

EARL *Marſhal of England*, is a great officer who had anciently ſeveral courts under his juriſdiction, as the court of chivalry, and the court of honour. Under him is alſo the herald's office or college of arms. He hath ſome pre-eminence in the court of Marſhalſea, where he may ſit in judgment againſt thoſe who offend within the verge of the king's court. The office is of great antiquity in England, and anciently of greater power than now: and has been for ſeveral ages hereditary in the moſt noble family of Howard.

EARNEST, ARRHÆ, money advanced to bind the parties to the performance of a verbal bargain. By the civil law, he who recedes from his bargain loſes his earneſt, and if the perſon who received the earneſt give back, he is to return the earneſt double. But with us, the perſon who gave it, is in ſtrictneſs obliged to abide by his bargain; and in caſe he decline it, is not diſcharged upon forfeiting his earneſt, but may be ſued for the whole money ſtipulated.

EARTH, among ancient philoſophers and chymiſts, one of the four elements of which the whole ſyſtem of nature was thought to be compoſed. See ELEMENT.

EARTH, in aſtronomy and geography, one of the primary planets; being this terraqueous globe which we inhabit.

THEORY OF THE EARTH.

Different Opinions reſpecting the Coſmogony.

The coſmogony, or knowledge of the original formation of the earth, the materials of which it was compoſed, and by what means they were diſpoſed in the order in which we ſee them at preſent, is a ſubject which, though perhaps above the reach of human ſagacity, has exerciſed the ſtudy of philoſophers in all ages. To recount the opinions of all the eminent philoſophers of antiquity upon this ſubject would be too tedious; it may therefore ſuffice to obſerve, that, ever ſince the ſubject began to be canvaſſed, the opinions of thoſe who have treated it may be divided into two claſſes.

1. Thoſe who believed the earth, and whole viſible ſyſtem of nature, to be the Deity himſelf, or connected with him in the ſame manner that a human body is with its ſoul. 2. Thoſe who believed the materials of it to have been eternal, but diſtinct from the Deity, and put into the preſent order by ſome power either inherent in themſelves, or belonging to the Deity. Of the firſt opinion were Xenophanes, the founder of the Eleatic ſect, Strato of Lampſacus, the Peripatetics, &c.

The ſecond opinion, namely, that the ſubſtance of the earth or univerſe (for it is impoſſible to ſpeak of the one without the other) was eternal, though not the form, was moſt generally held among the ancients. From that eſtabliſhed axiom, that "nothing can be produced from nothing," they concluded that creation was an impoſſibility; but at the ſame time they thought they had good reaſon to believe the world had not been always in its preſent form. They who held this opinion may again be divided into two claſſes; firſt, thoſe who endeavoured to account for the generation of the world, or its reduction into the preſent form, by principles merely mechanical, without having recourſe to any aſſiſtance from divine power; and ſecondly, thoſe who introduced an intelligent mind as the author and diſpoſer of all things. To the firſt of theſe claſſes belonged the coſmogony of the Babylonians, Phœnicians, and Egyptians; the particulars of which are too abſurd to deſerve notice. Of the ſame opinion alſo were moſt of the poets; the philoſophers Thales, Anaximander, Anaximenes, Anaxagoras, &c. The latter attempted to reform the philoſophy of his maſter Anaximenes by introducing an intelligent principle into the world, diſtinct from matter; thus making his intelligent principle, or God, the ſoul of the world. Diogenes of Apollonia ſuppoſed air, which he made the firſt principle of all things, to be endued with reaſon: His manner of philoſophiſing differed very little from that of Des Cartes. "All things, (ſays he,) being in motion, ſome became condenſed, and others rarefied. In thoſe places where condenſation prevailed, a whirling motion, or vortex, was formed; which by its revolution drew in the reſt, and the lighter parts flying upwards formed the ſun."

The hypotheſis of Democritus agrees in the main with that of Epicurus as repreſented by Lucretius. The moſt material difference between the two ſyſtems, however, was, that Epicurus admitted no principle but the atoms themſelves; whereas Democritus believed them to be animated.

Opinions of Pythagoras, Plato, and Ariſtotle.

Of thoſe who held two diſtinct and coeternal principles, viz. God and Matter, we ſhall only take notice of the opinions of Pythagoras, Plato, and Ariſtotle, as being the moſt remarkable. Pythagoras is ſaid to have aſſerted two ſubſtantial ſelf-exiſtent principles; a *monad*, or unity: and a *dyad*, or duality. The meaning of theſe terms is now ſomewhat uncertain. Some think, that by the monad, he meant the Deity; and, by the dyad, matter. Others think, that the Pythagoric monads were atoms. The dyad is ſometimes thought to ſignify a demon or evil principle; but Porphyry's interpretation, which ſeems the moſt probable, is as follows. The cauſe, ſays he, of that ſympathy, harmony, and agreement which is in things, and of the conſervation of the whole, which is always the ſame and like itſelf, was by Pythagoras called *unity*; that unity which is in the things, themſelves, being but a participation of the firſt cauſe: but the reaſon of difference, inequality, and conſtant irregularity in things, was by him called a *dyad*. This philoſopher held *numbers* to be the principles of all things, and from them he accounted for the production of the world in the following manner: He ſuppoſed that the moad and dyad were the two ſources of numbers, from whence proceeded points; from points, lines; from lines, plane figures; from planes, ſolids; from ſolids, ſenſible bodies. The elements of ſenſible bodies are four; but beſides theſe, there is a fifth (never yet diſcovered.) The four elements which manifeſt themſelves to our ſenſes are fire, air, earth, and water. Theſe are in a perpetual change, and from them the world was formed; which is animated, intelligent, and ſpherical; containing, in the midſt of it, the earth, a globoſe and inhabited body. The world, he ſaid, began from fire, and the fifth element; and that as there were five figures of ſolid bodies, called mathematical or regular, the earth was made of the cube, fire of the pyramid or tetrahedron, the air of the octahedron, water of the icoſahedron, and the ſphere of the univerſe of the dodecahedron. This method of philoſophizing, which has no manner of foundation in nature, was adopted by Plato and Ariſtotle: and hence proceeded all the abſurdities concerning ideas, forms, qualities, &c. with which the Ariſtotelian philoſophy was loaded.

For a long time, however, the philoſophy of Ariſtotle prevailed, and the world was thought to be upheld by forms, qualities, and other unintelligible and imaginary beings. At laſt the French philoſopher, Deſcartes, ſuperſeded the Ariſtotelian, by introducing the atomic, or Democritic, and Epicurean philoſophy. The Carteſian ſyſtem was quickly ſuperſeded by the Newtonian: which ſtill continues, though conſiderably different from what it was left by that great man.

Newtonian Syſtem ſupercedes the Ariſtotelian and Carteſian.

His opinions, indeed, concerning the coſmogony ſeem to have been in a fluctuating ſtate: and hence he delivers himſelf in ſuch a manner, that he hath often incurred the charge of contradicting himſelf. He maintained, for inſtance, that matter was infinitely diviſible, and the mathematical demonſtrations of this propoſition are well known. Notwithſtanding this, however, when he comes particularly to ſpeak of the original conſtruction of the world, he ſeems to retract this opinion, and adopt the atomic philoſophy. He tells us, that it ſeems probable, that in the beginning God formed matter in *ſolid, maſſy, impenetrable*, particles, &c.; and that of theſe particles, endowed with various powers of attraction and repulſion, the preſent ſyſtem of nature is formed.

Three Laws of Nature laid down by Sir Iſaac.

His primary laws of nature are only three in number, and very ſimple. The firſt is, that all matter has a tendency to continue in that ſtate in which it is once placed, whether of reſt or motion. If it is at reſt, for example, it will continue at reſt for ever, without beginning motion of itſelf; but if it is once ſet in motion, by any cauſe whatever, it will for ever continue to move in a right line, until ſomething either ſtops it altogether, or forces it to move in another direction. 2. That the change of motion is always equivalent to the moving force employed to produce it, and in the direction of the right line in which it is impreſſed; that is, if a certain force produces a certain motion, double that force will produce double that motion, &c. 3. Reaction is always contrary and equal to action; or the actions of two bodies upon one another are always equal and contrary to one another.

From theſe three laws, together with the two contrary forces of attraction and repulſion, Sir Iſaac Newton and his followers have attempted to explain all the phenomena of nature. When they come to explain the nature of the attractive and repulſive forces, however, they are exceedingly embarraſſed. Sir Iſaac hath expreſſed himſelf in two different ways concerning them. In his Principia, he pretty poſitively determines them to be owing to a cauſe that is not material; and in his queries, he ſuppoſes they may be effects of ſome ſubtile matter which he calls *ether*.

Diſagreement among his Followers.

This diſagreement with himſelf hath produced no ſmall diſagreement among his followers. One party, laying hold of his aſſertions in the Principia, determine the world to be upheld by immaterial powers; while the other, neglecting the Principia, and taking notice only of the queries at the end of the optics, ſtrenuouſly maintain, that attraction and repulſion are owing to the action of ſome exceedingly fine and ſubtile ether. The firſt of theſe ſuppoſitions, it is argued, neceſſarily involves us in one of the following dilemmas. 1. If the attractive and repulſive forces are not material, they muſt either be occaſioned by ſpiritual beings, or they muſt be qualities of matter. If they are occaſioned by the action of immaterial beings, theſe beings muſt either be created or uncreated. If they are produced by the action of created beings, we run into the ſuppoſition of ſome of the ancient heathens, that the world is governed by demons or ſubordinate intelligences; and thus may make an eaſy tranſition to polytheiſm. If attraction and repulſion are the immediate action of the deity himſelf, we run into the doctrine of making God the ſoul of the world. This laſt hypotheſis hath been moſt ſtrenuouſly adopted by Mr. Baxter in his treatiſe of the Immateriality of the human Soul.

Mr. Mitchel, Boſcovich, and Dr. Prieſtley's Opinions.

Mr. Boſcovich, Mr. Mitchel, and Dr. Prieſtley, have likewiſe adopted the hypotheſis of immaterial powers to ſuch a degree, that, according to them, the whole world conſiſts of nothing elſe but attractions and repulſions mixed with phyſical points. If we ſuppoſe the attractive and repulſive powers to be only properties, qualities, or laws, impreſſed on matter by the deity, we might as well have been contented with the occult qualities of Ariſtotle. If attraction and repulſion are occaſioned by the action of mere matter, and all the powers in nature are only material, the charge is incurred of making nature direct itſelf in ſuch a manner, that there is no occaſion for the interpoſition, or even the exiſtence, of a deity at all.

Thus we ſee, the Newtonian coſmogony muſt incline either to the Platonic and Ariſtotelian, or to the Atomic or Epicurean; according to the hypotheſis we lay down concerning the nature of attraction. Des Cartes's ſyſtem was plainly a revival of that of Democritus and Epicurus, with ſome corrections and improvements.

Mr. Hutchinſon's Syſtem.

It was further improved and corrected by Mr. Hutchinſon, who added to it the authority of Revelation. The created agents he choſe in his coſmogony were fire, light, and air. Theſe, we ſee, have indeed a very conſiderable ſhare in the operations of nature; but unleſs we explain the manner in which they operate, our knowledge is not at all increaſed, and we might as well have been contented with the Newtonian attraction and repulſion, or even the occult qualities of Ariſtotle. Attempts have indeed been made to ſolve the phenomena of nature, from the action of theſe three agents, both by Hutchinſon himſelf, and many of his followers. Theſe attempts, however, have always proved unſucceſsful. Some phenomena indeed may be explained pretty plauſibly from the known action of theſe three; but when we come to ſpeak of what may be called the nicer operations of nature, ſuch as the growth of plants and animals, we are utterly at a loſs.

A Deficiency of active Principles in all the Theories yet invented.

The manifeſt deficiency of active principles in all the theories of the earth that have yet been invented, hath occaſioned a conſtant ſearch after others which ſhould be able, by their ſuperior activity, to fill up the blank which neceſſarily remained in the ſyſtem. Pythagoras, Plato, and Ariſtotle, being unable to account for the formation of the earth from their four elements, called in the aſſiſtance of a fifth, which was never yet diſcovered. Epicurus, finding the motions attributed to his atoms by Democritus to be inſufficient, had recourſe to an imaginary, and on his own principles impoſſible, declination of the atoms. Deſcartes finding the atoms, themſelves inſufficient, aſſerted that they were not atoms, but might be broken into ſmaller parts, and thus conſtitute matter of various degrees of ſubtilty. The Newtonian philoſophers have found Des Cartes's ſyſtem inſufficient; but being greatly diſtreſſed in their attempts to ſolve all the phenomena of nature by mere attraction and repulſion, have been obliged to call in the action of mind to their aſſiſtance. The Hutchinſonians were hardly put to it in accounting for every thing by the action of fire, light, and air, when luckily the diſcoveries in electricity, came to their aſſiſtance. It muſt be owned that this fluid does indeed come in like a kind of fifth element, which in many caſes appears to be the animating principle of nature. For ſome time paſt, almoſt all the remarkable phenomena in nature have been explained by electricity, or the action of the electric fluid. But unleſs this action is explained, we are got no farther than we were before. To ſay any thing is done by electricity, is not more intelligible than to ſay it was done by attraction. If we explain an effect by a material cauſe, it ought to be done upon mechanical principles. We ought to be ſenſible how one part of matter acts upon another part in ſuch a manner as to produce the effect we deſire to explain. The electrical philoſophers, however, have not yet been able to inveſtigate the manner in which this ſubtile fluid operates; and hence the many diſcoveries in electricity have not contributed to throw that light on the theory of the earth, which perhaps they may do hereafter. With ſome philoſophers, however, the electric fluid itſelf, and indeed all the powers of nature, ſeem in danger of being ſuperſeded by a principle, at preſent very little known, called the phlogiſton.

Thus, Mr. Henly tells us, that Mr. Clarke, an ingenious gentleman in Ireland, hath diſcovered all the different kinds of air produced from metals, &c. by Dr. Prieſtley, to be only phlogiſtic vapours ariſing from theſe ſubſtances. Dr. Prieſtley himſelf ſuppoſes, that the electric light is a modification of phlogiſton; and conſequently thinks it probable, that all light is a modification of the ſame. Fire or flame is thought to be a chymical combination of air with the phlogiſton; and phlogiſton is thought to give the elaſticity to air, and every other elaſtic fluid, &c. Be this as it will, however, the late diſcoveries in electricity have tended very much to change the form of the Newtonian philoſophy.

Little Progreſs as yet made in true Philoſophy.

From this general hiſtory of the different agents which philoſophers have choſen to account for the original formation of the earth, and for its preſervation in the preſent form, it appears, that ſcarce any advance in true knowledge hath yet been made. All the agents have been prodigiouſly defective; electricity itſelf, as far as yet known, not excepted.

Many difficulties preſent themſelves to one who undertakes to write a natural hiſtory or theory of the earth. The moſt remarkable attempts to produce a theory of this kind are thoſe of Burnet, Woodward, Whiſton, and Buffon.

Dr. Burnet's Theory.

According to Dr. Burnet, the earth was originally a fluid maſs, or chaos compoſed of various ſubſtances differing both in denſity and figure. Thoſe which were moſt heavy ſunk to the centre, and formed there a hard ſolid body: thoſe which were ſpecifically lighter remaining next above: and the waters, which were lighteſt of all, covered the earth all round. The air, and other ethereal fluids, which are ſtill lighter than water, floated above it, and ſurrounded the globe alſo. Between the waters, however, and the circumambient air, was formed a coat of oily and unctuous matters lighter than water. The air at firſt was very impure, and muſt neceſſarily have carried up with it many of thoſe earthy particles with which it was once blended: however, it ſoon began to purify itſelf, and depoſit thoſe particles upon the oily cruſt abovementioned; which ſoon uniting together, the earth and oil became the cruſt of vegetable earth, with which the whole globe is now covered. His account of the deſtruction of the primæval world by the flood, by the falling down of the ſhell of earth into the waters of the abyſs, is given under the article **Deluge**. It only remains then to give his account of the manner in which he relieves the earth from this univerſal deſtruction; and this he does as follows: Theſe great maſſes of earth, ſays he, falling into the abyſs, drew down with them vaſt quantities alſo of air; and by daſhing againſt each other, and breaking into ſmall parts by the repeated violence of the ſhock, they at length left between them large cavities filled with nothing but air. Theſe cavities naturally offered a bed to receive the influent waters; and in proportion as they filled, the face of the earth became once more viſible. The higher parts of its broken ſurface, now become the tops of mountains, were the firſt that appeared; the plains ſoon after came forward; and at length the whole globe was delivered from the waters, except the places in the loweſt ſituations; ſo that the ocean and ſeas are ſtill a part of the ancient abyſs, that have had no place to which they might return. Iſlands and rocks are fragments of the earth's former cruſt; continents are larger maſſes of its broken ſubſtance; and all the inequalities that are to be found on the ſurface of the preſent earth are effects of the confuſion into which both earth and water were at that time thrown.

Dr. Woodward's.

Dr. Woodward begins with aſſerting, that all terrene ſubſtances are diſpoſed in beds of various natures, lying horizontally one over the other, ſomewhat like the coats of an onion: that they are replete with ſhells, and other productions of the ſea; theſe ſhells being found in the deepeſt cavities, and on the tops of the higheſt mountains. From theſe obſervations, which are warranted by experience, he proceeds to obſerve, that theſe ſhells, and extraneous foſſils, are not productions of the earth, but are all actual remains of thoſe animals which they are known to reſemble; that all the ſtrata or beds of the earth lie under each other in the order of their ſpecific gravity, and that they are diſpoſed as if they had been left there by ſubſiding waters. All this he very confidently affirms, though daily experience contradicts him in ſome and ſo the ſail is made faſt to the yard; and into the lowermoſt earings the ſheet and tackles are ſeized, or bent at the clew.

EARL, a Britiſh title of nobility, next below a marquis, and above a viſcount. The title is ſo ancient, that its original cannot be clearly traced out. This much, however, ſeems tolerably certain, that among the Saxons they were called *ealdormen*, *quaſi* elder men, ſignifying the ſame with *ſenior* or *ſenator* among the Romans; and alſo *ſchiremen*, becauſe they had each of them the civil government of a ſeveral diviſion or ſhire. On the irruption of the Danes they changed their names to *eorles*, which, according to Cambden, ſignified the ſame in their language. In Latin they are called *comites*, (a title firſt uſed in the empire), from being the king's attendants; *a ſocietate nomen ſumpſerunt, regis enim tales ſibi aſſociant.* After the Norman conqueſt they were for ſome time called *counts* or *countees*, from the French; but they did not long retain that name themſelves, though their ſhires are from thence called counties to this day. It is now become a mere title: they have nothing to do with the government of the county; which is now, entirely devolved on the ſheriff, the earl's deputy, or vicecomes. In writs, commiſſions, and other formal inſtruments, the king, when he mentions any peer of the degree of an earl, uſually ſtiles him "truſty and well beloved couſin:" an appellation as ancient as the reign of Henry IV; who being either by his wife, his mother, or his ſiſters, actually related or allied to every earl in the kingdom, artfully and conſtantly acknowledged that connexion in all his letters and other public acts: from whence the uſage has deſcended to his ſucceſſors, though the reaſon has long ago failed.

An earl is created by cincture of ſword, mantle of ſtate put upon him by the king himſelf, a cap and a coronet put upon his head, and a charter in his hand. All the earls of England are denominated from ſome ſhire, town, or place, except three; two of whom, viz. earl Rivers, and earl Paulet, take their denomination from illuſtrious families: the third is not only honorary as all the reſt, but alſo officiary, as the earl marſhal of England. See Syſtem of PEERAGE.

EARL *Marſhal of England*, is a great officer who had anciently ſeveral courts under his juriſdiction, as the court of chivalry, and the court of honour. Under him is alſo the herald's office or college of arms. He hath ſome pre-eminence in the court of Marſhalſea, where he may ſit in judgment againſt thoſe who offend within the verge of the king's court. The office is of great antiquity in England, and anciently of greater power than now: and has been for ſeveral ages hereditary in the moſt noble family of Howard.

EARNEST, ARRHÆ, money advanced to bind the parties to the performance of a verbal bargain. By the civil law, he who recedes from his bargain loſes his earneſt, and if the perſon who received the earneſt give back, he is to return the earneſt double. But with us, the perſon who gave it, is in ſtrictneſs obliged to abide by his bargain; and in caſe he decline it, is not diſcharged upon forfeiting his earneſt, but may be ſued for the whole money ſtipulated.

EARTH, among ancient philoſophers and chymiſts, one of the four elements of which the whole ſyſtem of nature was thought to be compoſed. See ELEMENT.

EARTH, in aſtronomy and geography, one of the primary planets; being this terraqueous globe which we inhabit.

THEORY OF THE EARTH.

Different Opinions reſpecting the Coſmogony.

The coſmogony, or knowledge of the original formation of the earth, the materials of which it was compoſed, and by what means they were diſpoſed in the order in which we ſee them at preſent, is a ſubject which, though perhaps above the reach of human ſagacity, has exerciſed the ſtudy of philoſophers in all ages. To recount the opinions of all the eminent philoſophers of antiquity upon this ſubject would be too tedious; it may therefore ſuffice to obſerve, that, ever ſince the ſubject began to be canvaſſed, the opinions of thoſe who have treated it may be divided into two claſſes.

1. Thoſe who believed the earth, and whole viſible ſyſtem of nature, to be the Deity himſelf, or connected with him in the ſame manner that a human body is with its ſoul. 2. Thoſe who believed the materials of it to have been eternal, but diſtinct from the Deity, and put into the preſent order by ſome power either inherent in themſelves, or belonging to the Deity. Of the firſt opinion were Xenophanes, the founder of the Eleatic ſect, Strato of Lampſacus, the Peripatetics, &c.

The ſecond opinion, namely, that the ſubſtance of the earth or univerſe (for it is impoſſible to ſpeak of the one without the other) was eternal, though not the form, was moſt generally held among the ancients. From that eſtabliſhed axiom, that "nothing can be produced from nothing," they concluded that creation was an impoſſibility; but at the ſame time they thought they had good reaſon to believe the world had not been always in its preſent form. They who held this opinion may again be divided into two claſſes; firſt, thoſe who endeavoured to account for the generation of the world, or its reduction into the preſent form, by principles merely mechanical, without having recourſe to any aſſiſtance from divine power; and ſecondly, thoſe who introduced an intelligent mind as the author and diſpoſer of all things. To the firſt of theſe claſſes belonged the coſmogony of the Babylonians, Phœnicians, and Egyptians; the particulars of which are too abſurd to deſerve notice. Of the ſame opinion alſo were moſt of the poets; the philoſophers Thales, Anaximander, Anaximenes, Anaxagoras, &c. The latter attempted to reform the philoſophy of his maſter Anaximenes by introducing an intelligent principle into the world, diſtinct from matter; thus making his intelligent principle, or God, the ſoul of the world. Diogenes of Apollonia ſuppoſed air, which he made the firſt principle of all things, to be endued with reaſon: His manner of philoſophiſing differed very little from that of Des Cartes. "All things, (ſays he,) being in motion, ſome became condenſed, and others rarefied. In thoſe places where condenſation prevailed, a whirling motion, or vortex, was formed; which by its revolution drew in the reſt, and the lighter parts flying upwards formed the ſun."

The hypotheſis of Democritus agrees in the main with that of Epicurus as repreſented by Lucretius. The moſt material difference between the two ſyſtems, however, was, that Epicurus admitted no principle but the atoms themſelves; whereas Democritus believed them to be animated.

Opinions of Pythagoras, Plato, and Ariſtotle.

Of thoſe who held two diſtinct and coeternal principles, viz. God and Matter, we ſhall only take notice of the opinions of Pythagoras, Plato, and Ariſtotle, as being the moſt remarkable. Pythagoras is ſaid to have aſſerted two ſubſtantial ſelf-exiſtent principles; a *monad*, or unity: and a *dyad*, or duality. The meaning of theſe terms is now ſomewhat uncertain. Some think, that by the monad, he meant the Deity; and, by the dyad, matter. Others think, that the Pythagoric monads were atoms. The dyad is ſometimes thought to ſignify a demon or evil principle; but Porphyry's interpretation, which ſeems the moſt probable, is as follows. The cauſe, ſays he, of that ſympathy, harmony, and agreement which is in things, and of the conſervation of the whole, which is always the ſame and like itſelf, was by Pythagoras called *unity*; that unity which is in the things, themſelves, being but a participation of the firſt cauſe: but the reaſon of difference, inequality, and conſtant irregularity in things, was by him called a *dyad*. This philoſopher held *numbers* to be the principles of all things, and from them he accounted for the production of the world in the following manner: He ſuppoſed that the moad and dyad were the two ſources of numbers, from whence proceeded points; from points, lines; from lines, plane figures; from planes, ſolids; from ſolids, ſenſible bodies. The elements of ſenſible bodies are four; but beſides theſe, there is a fifth (never yet diſcovered.) The four elements which manifeſt themſelves to our ſenſes are fire, air, earth, and water. Theſe are in a perpetual change, and from them the world was formed; which is animated, intelligent, and ſpherical; containing, in the midſt of it, the earth, a globoſe and inhabited body. The world, he ſaid, began from fire, and the fifth element; and that as there were five figures of ſolid bodies, called mathematical or regular, the earth was made of the cube, fire of the pyramid or tetrahedron, the air of the octahedron, water of the icoſahedron, and the ſphere of the univerſe of the dodecahedron. This method of philoſophizing, which has no manner of foundation in nature, was adopted by Plato and Ariſtotle: and hence proceeded all the abſurdities concerning ideas, forms, qualities, &c. with which the Ariſtotelian philoſophy was loaded.

For a long time, however, the philoſophy of Ariſtotle prevailed, and the world was thought to be upheld by forms, qualities, and other unintelligible and imaginary beings. At laſt the French philoſopher, Deſcartes, ſuperſeded the Ariſtotelian, by introducing the atomic, or Democritic, and Epicurean philoſophy. The Carteſian ſyſtem was quickly ſuperſeded by the Newtonian: which ſtill continues, though conſiderably different from what it was left by that great man.

Newtonian Syſtem ſupercedes the Ariſtotelian and Carteſian.

His opinions, indeed, concerning the coſmogony ſeem to have been in a fluctuating ſtate: and hence he delivers himſelf in ſuch a manner, that he hath often incurred the charge of contradicting himſelf. He maintained, for inſtance, that matter was infinitely diviſible, and the mathematical demonſtrations of this propoſition are well known. Notwithſtanding this, however, when he comes particularly to ſpeak of the original conſtruction of the world, he ſeems to retract this opinion, and adopt the atomic philoſophy. He tells us, that it ſeems probable, that in the beginning God formed matter in *ſolid, maſſy, impenetrable*, particles, &c.; and that of theſe particles, endowed with various powers of attraction and repulſion, the preſent ſyſtem of nature is formed.

Three Laws of Nature laid down by Sir Iſaac.

His primary laws of nature are only three in number, and very ſimple. The firſt is, that all matter has a tendency to continue in that ſtate in which it is once placed, whether of reſt or motion. If it is at reſt, for example, it will continue at reſt for ever, without beginning motion of itſelf; but if it is once ſet in motion, by any cauſe whatever, it will for ever continue to move in a right line, until ſomething either ſtops it altogether, or forces it to move in another direction. 2. That the change of motion is always equivalent to the moving force employed to produce it, and in the direction of the right line in which it is impreſſed; that is, if a cerrain force produces a certain motion, double that force will produce double that motion, &c. 3. Reaction is always contrary and equal to action; or the actions of two bodies upon one another are always equal and contrary to one another.

From theſe three laws, together with the two contrary forces of attraction and repulſion, Sir Iſaac Newton and his followers have attempted to explain all the phenomena of nature. When they come to explain the nature of the attractive and repulſive forces, however, they are exceedingly embarraſſed. Sir Iſaac hath expreſſed himſelf in two different ways concerning them. In his Principia, he pretty poſitively determines them to be owing to a cauſe that is not material; and in his queries, he ſuppoſes they may be effects of ſome ſubtile matter which he calls *ether*.

Diſagreement among his Followers.

This diſagreement with himſelf hath produced no ſmall diſagreement among his followers. One party, laying hold of his aſſertions in the Principia, determine the world to be upheld by immaterial powers; while the other, neglecting the Principia, and taking notice only of the queries at the end of the optics, ſtrenuouſly maintain, that attraction and repulſion are owing to the action of ſome exceedingly fine and ſubtile ether. The firſt of theſe ſuppoſitions, it is argued, neceſſarily involves us in one of the following dilemmas. 1. If the attractive and repulſive forces are not material, they muſt either be occaſioned by ſpiritual beings, or they muſt be qualities of matter. If they are occaſioned by the action of immaterial beings, theſe beings muſt either be created or uncreated. If they are produced by the action of created beings, we run into the ſuppoſition of ſome of the ancient heathens, that the world is governed by demons or ſubordinate intelligences; and thus may make an eaſy tranſition to polytheiſm. If attraction and repulſion are the immediate action of the deity himſelf, we run into the doctrine of making God the ſoul of the world. This laſt hypotheſis hath been moſt ſtrenuouſly adopted by Mr. Baxter in his treatiſe of the Immateriality of the human Soul.

Mr. Mitchel, Boſcovich, and Dr. Prieſtley's Opinions.

Mr. Boſcovich, Mr. Mitchel, and Dr. Prieſtley, have likewiſe adopted the hypotheſis of immaterial powers to ſuch a degree, that, according to them, the whole world conſiſts of nothing elſe but attractions and repulſions mixed with phyſical points. If we ſuppoſe the attractive and repulſive powers to be only properties, qualities, or laws, impreſſed on matter by the deity, we might as well have been contented with the occult qualities of Ariſtotle. If attraction and repulſion are occaſioned by the action of mere matter, and all the powers in nature are only material, the charge is incurred of making nature direct itſelf in ſuch a manner, that there is no occaſion for the interpoſition, or even the exiſtence, of a deity at all.

Thus we ſee, the Newtonian coſmogony muſt incline either to the Platonic and Ariſtotelian, or to the Atomic or Epicurean; according to the hypotheſis we lay down concerning the nature of attraction. Des Cartes's ſyſtem was plainly a revival of that of Democritus and Epicurus, with ſome corrections and improvements.

Mr. Hutchinſon's Syſtem.

It was further improved and corrected by Mr. Hutchinſon, who added to it the authority of Revelation. The created agents he choſe in his coſmogony were fire, light, and air. Theſe, we ſee, have indeed a very conſiderable ſhare in the operations of nature; but unleſs we explain the manner in which they operate, our knowledge is not at all increaſed, and we might as well have been contented with the Newtonian attraction and repulſion, or even the occult qualities of Ariſtotle. Attempts have indeed been made to ſolve the phenomena of nature, from the action of theſe three agents, both by Hutchinſon himſelf, and many of his followers. Theſe attempts, however, have always proved unſucceſsful. Some phenomena indeed may be explained pretty plauſibly from the known action of theſe three; but when we come to ſpeak of what may be called the nicer operations of nature, ſuch as the growth of plants and animals, we are utterly at a loſs.

A Deficiency of active Principles in all the Theories yet invented.

The manifeſt deficiency of active principles in all the theories of the earth that have yet been invented, hath occaſioned a conſtant ſearch after others which ſhould be able, by their ſuperior activity, to fill up the blank which neceſſarily remained in the ſyſtem. Pythagoras, Plato, and Ariſtotle, being unable to account for the formation of the earth from their four elements, called in the aſſiſtance of a fifth, which was never yet diſcovered. Epicurus, finding the motions attributed to his atoms by Democritus to be inſufficient, had recourſe to an imaginary, and on his own principles impoſſible, declination of the atoms. Deſcartes finding the atoms, themſelves inſufficient, aſſerted that they were not atoms, but might be broken into ſmaller parts, and thus conſtitute matter of various degrees of ſubtilty. The Newtonian philoſophers have found Des Cartes's ſyſtem inſufficient; but being greatly diſtreſſed in their attempts to ſolve all the phenomena of nature by mere attraction and repuſion, have been obliged to call in the action of mind to their aſſiſtance. The Hutchinſonians were hardly put to it in accounting for every thing by the action of fire, light, and air, when luckily the diſcoveries in electricity came to their aſſiſtance. It muſt be owned that this fluid does indeed come in like a kind of fifth element, which in many caſes appears to be the animating principle of nature. For ſome time paſt, almoſt all the remarkable phenomena in nature have been explained by electricity, or the action of the electric fluid. But unleſs this action is explained, we are got no farther than we were before. To ſay any thing is done by electricity, is not more intelligible than to ſay it was done by attraction. If we explain an effect by a material cauſe, it ought to be done upon mechanical principles. We ought to be ſenſible how one part of matter acts upon another part in ſuch a manner as to produce the effect we deſire to explain. The electrical philoſophers, however, have not yet been able to inveſtigate the manner in which this ſubtile fluid operates; and hence the many diſcoveries in electricity have not contributed to throw that light on the theory of the earth, which perhaps they may do hereafter. With ſome philoſophers, however, the electric fluid itſelf, and indeed all the powers of nature, ſeem in danger of being ſuperſeded by a principle, at preſent very little known, called the phlogiſton.

Thus, Mr. Henly tells us, that Mr. Clarke, an ingenious gentleman in Ireland, hath diſcovered all the different kinds of air produced from metals, &c. by Dr. Prieſtley, to be only phlogiſtic vapours ariſing from theſe ſubſtances. Dr. Prieſtley himſelf ſuppoſes, that the electric light is a modification of phlogiſton; and conſequently thinks it probable, that all light is a modification of the ſame. Fire or flame is thought to be a chymical combination of air with the phlogiſton; and phlogiſton is thought to give the elaſticity to air, and every other elaſtic fluid, &c. Be this as it will, however, the late diſcoveries in electricity have tended very much to change the form of the Newtonian philoſophy.

Little Progreſs as yet made in true Philoſophy.

From this general hiſtory of the different agents which philoſophers have choſen to account for the original formation of the earth, and for its preſervation in the preſent form, it appears, that ſcarce any advance in true knowledge hath yet been made. All the agents have been prodigiouſly defective; electricity itſelf, as far as yet known, not excepted.

Many difficulties preſent themſelves to one who undertakes to write a natural hiſtory or theory of the earth. The moſt remarkable attempts to produce a theory of this kind are thoſe of Burnet, Woodward, Whiſton, and Buffon.

Dr. Burnet's Theory.

According to Dr. Burnet, the earth was originally a fluid maſs, or chaos compoſed of various ſubſtances differing both in denſity and figure. Thoſe which were moſt heavy ſunk to the centre, and formed there a hard ſolid body: thoſe which were ſpecifically lighter remaining next above: and the waters, which were lighteſt of all, covered the earth all round. The air, and other ethereal fluids, which are ſtill lighter than water, floated above it, and ſurrounded the globe alſo. Between the waters, however, and the circumambient air, was formed a coat of oily and unctuous matters lighter than water. The air at firſt was very impure, and muſt neceſſarily have carried up with it many of thoſe earthy particles with which it was once blended: however, it ſoon began to purify itſelf, and depoſit thoſe particles upon the oily cruſt abovementioned; which ſoon uniting together, the earth and oil became the cruſt of vegetable earth, with which the whole globe is now covered. His account of the deſtruction of the primæval world by the flood, by the falling down of the ſhell of earth into the waters of the abyſs, is given under the article DELUGE. It only remains then to give his account of the manner in which he relieves the earth from this univerſal deſtruction; and this he does as follows: Theſe great maſſes of earth, ſays he, falling into the abyſs, drew down with them vaſt quantities alſo of air; and by daſhing againſt each other, and breaking into ſmall parts by the repeated violence of the ſhock, they at length left between them large cavities filled with nothing but air. Theſe cavities naturally offered a bed to receive the influent waters; and in proportion as they filled, the face of the earth became once more viſible. The higher parts of its broken ſurface, now become the tops of mountains, were the firſt that appeared; the plains ſoon after came forward; and at length the whole globe was delivered from the waters, except the places in the loweſt ſituations; ſo that the ocean and ſeas are ſtill a part of the ancient abyſs, that have had no place to which they might return. Iſlands and rocks are fragments of the earth's former cruſt; continents are larger maſſes of its broken ſubſtance; and all the inequalities that are to be found on the ſurface of the preſent earth are effects of the confuſion into which both earth and water were at that time thrown.

Dr. Woodward's.

Dr. Woodward begins with aſſerting, that all terrene ſubſtances are diſpoſed in beds of various natures, lying horizontally one over the other, ſomewhat like the coats of an onion: that they are replete with ſhells, and other productions of the ſea; theſe ſhells being found in the deepeſt cavities, and on the tops of the higheſt mountains. From theſe obſervations, which are warranted by experience, he proceeds to obſerve, that theſe ſhells, and extraneous foſſils, are not productions of the earth, but are all actual remains of thoſe animals which they are known to reſemble; that all the ſtrata or beds of the earth lie under each other in the order of their ſpecific gravity, and that they are diſpoſed as if they had been left there by ſubſiding waters. All this he very confidently affirms, though daily experience contradicts him in ſome of them; particularly, we often find layers of ſtone over the lighteſt ſoils, and the ſofteſt earth under the hardeſt bodies. However, having taken it for granted, that all the layers of the earth are found in the order of their ſpecific gravity, the lighteſt at top, and the heavieſt next the centre, he conſequently aſſerts, that all the ſubſtances of which the earth is compoſed, were originally in a ſtate of diſſolution. This diſſolution he ſuppoſes to have taken place at the flood: but being aware of an objection, that the ſhells, &c. ſuppoſed to have been depoſited at the flood are not diſſolved, he exempts them from the ſolvent power of the waters, and endeavours to ſhew that they have a ſtronger coheſion than minerals; and that, while even the hardeſt rocks are diſſolved, bones and ſhells may remain entire.

Mr. Whiſton's.

Mr. Whiſton ſuppoſes the earth to have been originally a comet; and conſiders the Moſaic account of the creation as commencing at the time when the Creator placed this comet in a more regular manner, and made it a planet in the ſolar ſyſtem. Before that time, he ſuppoſes it to have been a globe without beauty or proportion; a world in diſorder ſubject to all the viciſſitudes which comets endure; which, according to the preſent ſyſtem of philoſophy, muſt be alternately expoſed to the extremes of heat and cold. Theſe alterations of heat, and cold, continually melting and freezing the ſurface of the earth, he ſuppoſes to have produced to a certain depth, a chaos reſembling that deſcribed by the poets, ſurrounding the ſolid contents of the earth, which ſtill continued unchanged in the midſt; making a great burning globe of more than 2000 leagues in diameter. This ſurrounding chaos, however, was far from being ſolid: he reſembles it to a denſe, though fluid atmoſphere, compoſed of ſubſtances mingled, agitated and ſhocked againſt each other: and in this diſorder he ſuppoſes the earth to have been juſt at the eve of the Moſaic creation. But upon its orbit being then changed, when it was more regularly wheeled round the ſun, every thing took its proper place, every part of the ſurrounding fluid then fell into a certain ſituation according as it was light or heavy. The middle, or central part, which always remained unchanged, ſtill continued ſo; retaining a part of that heat which it received in its primæval approaches towards the ſun; which heat he calculates may continue about 6000 years. Next to this fell the heavier parts of the chaotic atmoſphere, which ſerve to ſuſtain the lighter: but as in deſcending they could not entirely be ſeparated from many watery parts, with which they were intimately mixed, they drew down theſe alſo along with them; and theſe could not mount again after the ſurface of the earth was conſolidated: they therefore ſurrounded the heavy firſt deſcending parts in the ſame manner as theſe ſurrounded the central globe. Thus the entire body of the earth is compoſed next the centre of a great burning globe: next this is placed an heavy terrene ſubſtance that encompaſſes it; round which is circumfuſed a body of water. Upon this body of waters is placed the cruſt of earth on which we inhabit: ſo that, according to Mr. Whiſton, the globe is compoſed of a number of coats, or ſhells, one within the other, all of different denſities. The body of the earth being thus formed, the air, which is the lighteſt ſuſtance of all, ſurrounded its ſurface; and the beams of the ſun darting through, produced the light, which, we are told by Moſes, firſt obeyed the Divine command.

The whole œconomy of the creation being thus adjuſted, it only remained to account for the riſings and depreſſions on the ſurface of the earth, with the other ſeeming irregularities, of its preſent appearance. The hills and valleys are by him conſidered as formed by their preſſing upon the internal fluid which ſuſtains the external ſhell of earth, with greater or leſs weight: thoſe parts of the earth which are heavieſt ſink the loweſt into the ſubjacent fluid, and thus become valleys: thoſe that are lighteſt riſe higher upon the earth's ſurface, and are called mountains.

Such was the face of nature before the deluge: the earth was then more fertile and populous than it is at preſent; the life of men and animals was extended to ten times its preſent duration; and all theſe advantages aroſe from the ſuperior heat of the central globe, which has ever ſince been cooling. As its heat was then in its full power, the genial principle was alſo much greater than at preſent; vegetation and animal increaſe were carried on with more vigour; and all nature ſeemed teeming with the ſeeds of life. But as theſe advantages were productive only of moral evil, it was found neceſſary to deſtroy all living creatures by a flood.

Mr. Buffon's Theory.

Mr. Buffon's theory differs very widely from all the reſt. He begins with attempting to prove, that this world which we inhabit is no more than the ruins of a world. "The ſurface of this immenſe globe, ſays he, exhibits to our obſervation, heights, depths, plains, ſeas, marſhes, rivers, caverns, gulfs, volcanoes; and, on a curſory view, we can diſcover in the diſpoſition of theſe objects neither order nor regularity. If we penetrate into the bowels of the earth, we find metals, minerals, ſtones, bitumens, ſands, earths, waters, and matter of every kind, placed as it were by mere accident, and without any apparent deſign. Upon a nearer and more attentive inſpection, we diſcover ſunk mountains, caverns filled up, ſhattered rocks, whole countries ſwallowed up, new iſlands emerged from the ocean, heavy ſubſtances placed above light ones, hard bodies incloſed within ſoft bodies: in a word, we find matter in every form, dry and humid, warm and cold, ſolid and brittle, blended in a chaos of confuſion, which can be compared to nothing but a heap of rubbiſh, or the ruins of a world."

I am convinced, ſays Mr. Buffon, from repeated obſervation, that marbles, limeſtones, chalks, marles, clays, ſand, and almoſt all terreſtrial ſubſtances, wherever ſituated, are full of ſhells and other ſpoils of the ocean.

From theſe poſitions, which he lays down as facts, Mr. Buffon draws the following concluſions:

1. The changes which the earth has undergone within theſe laſt 2000 or 3000 years muſt be inconſiderable, when compared with the great revolutions that took place in thoſe ages immediately ſucceeding the creation. The reaſon he gives for this aſſertion is, that terreſtrial ſubſtances could not acquire ſolidity but by the continued action of gravity: hence, the earth muſt have been originally much ſofter than it is now, and therefore more apt to be changed by cauſes which cannot now affect it.

2. It ſeems an uncontrovertible fact, that the dry land which we now inhabit, and even the ſummits of the higheſt mountains, were formerly covered with the waters of the ſea; for ſhells and other marine bodies are ſtill found upon the very tops of mountains.

3. The waters of the ſea have remained for a long track of time upon the ſurface: becauſe in many places, ſuch immenſe banks of ſhells have been diſcovered, that it is impoſſible ſo great a multitude of animals could exiſt at the ſame time.

4. From this circumſtance it likewiſe appears, that, although the materials on the ſurface of the earth were then ſoft, eaſily diſunited, moved, and tranſported by the waters, yet theſe tranſportations could not be ſuddenly effected: they muſt have been gradual and ſucceſſive, as ſea bodies are ſometimes found more than 1000 feet below the ſurface; and ſuch a thickneſs of earth, or ſtone, could not be accumulated in a ſhort time.

5. It is impoſſible theſe effects could be owing to the univerſal deluge. For, though we ſhould ſuppoſe that all the ſhells in the bottom of the ocean ſhould be depoſited upon the dry land; yet, beſides the difficulty of eſtabliſhing this ſuppoſition, it is plain, that as ſhells are found incorporated in marble, and in the rocks of the higheſt mountains, we muſt ſuppoſe theſe rocks and marbles to have been formed all at the very inſtant when the deluge took place; and that before this grand revolution, there were neither mountains, nor marbles, nor rocks, nor clays, nor matter of any kind ſimilar to what we are now acquainted with; as they all, with few exceptions, contain ſhells, and other productions of the ocean; Beſides, at the time of the univerſal deluge, the earth muſt have acquired a conſiderable degree of ſolidity, by the action of gravity for more than ſixteen centuries. During the ſhort time the deluge laſted, therefore, it is impoſſible that the waters ſhould have overturned and diſſolved the whole ſurface of the earth to the greateſt depths.

6. It is certain, (for what reaſon he does not mention), that the waters of the ſea have, at ſome period or other, remained for a ſucceſſion of ages upon what we know to be dry land; and conſequently that the vaſt continents of Aſia, Europe, Africa, and America, were then the bottom of an immenſe ocean, replete with every thing which the preſent ocean produces.

How the Earth was deſerted by the Ocean and left dry.

Having thus diſcuſſed ſome very important points reſpecting the theory of the earth, our author now proceeds to anſwer other queſtions which ſeem more difficult of ſolution.

7. But how has it happened that this earth, which we and our anceſtors have inhabited for ages, which, from time immemorial, has been an immenſe continent, dry, compact, and removed from the reach of water, ſhould, if formerly the bottom of an ocean, be now exalted to ſuch a height above the waters, and ſo completely ſeparated from them. Since the waters remained ſo long upon the earth, why have they now deſerted it? What accident, what cauſe, could introduce a change ſo great? A little reflection, ſays he, will furniſh us with at leaſt plauſible ſolutions to theſe ſeemingly ſo difficult queſtions. We daily obſerve the ſea gaining ground on certain coaſts, and loſing it on others. We know that the ocean has a general and uniform motion from eaſt to weſt: that it makes violent efforts againſt the rocks and low grounds which encircle it; that there are whole provinces which human induſtry can hardly defend from the fury of the waves; and that there are inſtances of iſlands which have but lately emerged from the waters, and of regular inundations. Hiſtory informs us of inundations and deluges of a more extenſive nature. Ought not all this to convince us, that the ſurface of the earth has experienced very great revolutions, and that the ſea may have actually given up poſſeſſion of the greateſt part of the ground which it formerly occupied? For example, let us ſuppoſe, that the old and new worlds were formerly but one continent; and that, by a violent earthquake, the ancient Atlantis of Plato was ſunk. The conſequence of this mighty revolution muſt neceſſarily be, that the ſea would ruſh in from all quarters, and form what is now called the Atlantic ocean; and vaſt continents, perhaps thoſe we now inhabit, would of courſe be left dry. This great revolution might be effected by the ſudden failure of ſome immenſe cavern in the

interior parts of the globe, and an univerſal deluge would infallibly ſucceed.

8. But, however conjectures of this kind may ſtand, it is certain that ſuch a revolution hath happened: and we may even believe that it hath happened naturally; for if a judgment of the future is to be formed from the paſt, we have only to attend carefully to what paſſes before our eyes. It is a fact eſtabliſhed by the repeated obſervation of voyagers, that the ocean has a conſtant motion from eaſt to weſt. This motion, like the trade-winds, is not only perceived between the tropics, but though the whole temperate climates, and as near the poles as navigators have approached. As a neceſſary conſequence of this motion, the Pacific Ocean muſt make continual efforts againſt the coaſts of Tartary, China, and India; the Indian ocean muſt act againſt the eaſt coaſt of Africa; and the Atlantic muſt in a ſimilar manner act againſt all the eaſtern coaſts of America. Hence the ſea muſt have gained, and will always continue to gain, on the eaſt, and to loſe on the weſt. This of itſelf would be ſufficient to prove the poſſibility of the change of the ſea into land, and land into ſea. If ſuch is the natural effect of the ſea's motion from eaſt to weſt, may it not reaſonably be ſuppoſed, that Aſia, and all the eaſtern continent, is the moſt ancient country in the world; and that Europe, and part of Africa, eſpecially the weſt parts of theſe continents, as Britain, France, Spain, &c. are countries of a more recent date?

Buffon's Account of the Formation of the Planets.

Thus far our author preſerves ſome degree of plauſibility in his reaſoning; but in his account of the original formation of the earth, he certainly goes to the utmoſt verge of probability, or perhaps of poſſibility, in his ſuppoſitions. According to him, all the planets in our ſyſtem were originally parts of the ſun himſelf. They were detached from his body all at once by a mighty ſtroke of a comet. The poſſibility of driving off ſuch a quantity of matter from the ſun by a ſingle ſtroke, he labours hard to prove; but this is far from being the greateſt difficulty in his ſyſtem. "To this theory, ſays he, it may be objected, that if the planets had been driven off from the ſun by a comet, in place of deſcribing circles round him, they muſt, according to the law of projectiles, have returned to the ſame place from whence they had been forced; and therefore, that the projectile force of the planets cannot be attributed to the impulſe of a comet."

All Theories inſufficient, as well as Powers of Attraction and Repulſion.

From the preceding extracts, the theories of Drs. Burnet and Woodward, as well as Meſſrs. Whiſton and Buffon, will be eaſily underſtood; but the deficiency of all of them muſt be exceedingly obvious even to the moſt ſuperficial reader. They all aſſume only the powers of attraction and repulſion as agents; without conſidering, that theſe two powers, or indeed any other two with which we are acquainted, could only have compoſed matters nearly ſimilar to each other. If the original particles of matter are homogeneous, and endowed with ſimilar powers, all the matter we ſee ought to be homogeneous alſo. But this is far from being the caſe. Some parts of it we ſee are exceedingly hard, others proportionably ſoft. The parts of ſome bodies attract each other violently; thoſe of others have hardly any attraction for each other, but are ſeparable by the ſmalleſt force. And though it ſhould be granted, that the powers of attraction and repulſion were originally different in different parts of matter, we have ſtill to explain by what means the ſimilar parts of matter found out each other in ſuch a chaos as the earth originally was. This ſeems an inſuperable difficulty in the ſyſtems of Drs. Burnet and Woodward; and is equally, though leſs conſpicuouſly ſo, in thoſe of Whiſton and Buffon.

Deficiency of Mr. Whiſton's Theory.

Mr. Whiſton's ſyſtem has another and very remarkable defect. He ſuppoſes the earth to have been originally a comet, and at a certain time to have become a planet: but he forgets to tell us by what means this comet was originally formed, or what kind of bodies the comets are. Yet certainly this theory of the comet was as neceſſary to his ſyſtem, as the theory of the earth itſelf: for all the ſubſtances now exiſting on the earth muſt originally have exiſted in the comet; and if the natural powers were known, which made a diſtinction between one ſubſtance and another in the comet, we ſhould alſo know thoſe which diſtinguiſhed terreſtrial ſubſtances from one another. But though even this great deficiency ſhould be overlooked, the ſuppoſition of a chaos or original confuſion of any kind involves us in the greateſt difficulties. If the whole ſurface of the earth conſiſted of a chaos of melted matter, we cannot reaſonably think it would have appeared otherwiſe when cool than the lavas of burning mountains do juſt now; and this is a conſequence of his ſyſtem which Mr. Whiſton ſeems to have entirely overlooked.

Of Mr. Buffon's.

Mr. Buffon's theory is liable to the ſame difficulties with the reſt. He places his chaos in the ſun, and therefore ought to have given a theory of the ſun before he gave one of the earth. It ought alſo to have been ſhewn for what purpoſe the ſun was created when he had nothing to ſhine upon, or what probability there is that comets exiſted when there were no planets. His account of the formation of the planets by the ſtroke of a comet, is juſt within the verge of poſſibility; but his account of the formation of mountains by the motion of the winds and tides, is certainly inconſiſtent with the common principles of mechanics.

But what in the ſtrongeſt manner ſhews the fallacy of Mr. Buffon's hypotheſis, is the analogy he draws between mountains on dry land, and iſlands in the ſea. The iſlands, he ſays, are only the tops of great mountains in the ocean. If therefore the ocean had for a ſeries of many ages covered the preſent habitable part of the world, as our author ſuppoſes, we ſhould undoubtedly find many mountains upon the dry land, the tops of which had formerly been iſlands. But no ſuch thing is to be found. There is not on earth a mountain with a top broad and flat like the iſland of Great-Britain or Ireland, or even like iſlands of much leſs conſideration.

Theſe, and many other objections that will naturally occur to an attentive reader, ſhew the extreme difficulties under which the hypotheſis of Mr. Buffon labours, as well as others.

A Number of Natural Powers beſides Attraction and Repulſion proved to exiſt.

Though it is certain that the powers of attraction and repulſion exiſt in nature, it is no leſs certain that there are many others. One very remarkable power entirely different from thoſe of attraction and repulſion, may be called the power of aſſimilation or tranſmutation. By this, each animal, and each plant, changes the nutritious particles thrown into its ſtomach, or which it meets with in the earth, into a ſubſtance of its own peculiar kind. Thus, a ſtalk of wheat, by means of its roots, always aſſimilates the nutritious particles of the ground into that particular grain we call wheat, and no other. This power naturaliſts have not been able to explain, on the principles of attraction and repulſion, or any others with which we are acquainted; and therefore it may juſtly be called one of the primary laws of this earth at leaſt, whether we underſtand the manner in which it operates or not. Another power which ſeems to be diffuſed throughout this terraqueous globe, and common to all ſubſtances, water alone excepted, is that of multiplying themſelves, or producing others of the ſame ſpecies. With regard to plants and animals, this is exceedingly evident; but may be diſputed in the caſe of minerals. It is certain, however, that mines which have been exhauſted, will in time be again repleniſhed with ore; that ſpars and cryſtals, if broken or cut while their connection with the earth remains, will protrude a ſubſtance ſimilar to the reſt, as certainly as the wounded body of an animal will protrude fleſh of a kind ſimilar to what was taken away. The earth itſelf is capable of this multiplication. We ſee how it has a tendency to aſcend, and cover ſtones, &c. which lie a long time on the ſurface; and thus does this element, ſeemingly the moſt ſluggiſh of all others, ſwallow up every thing that lies for ſome time undiſturbed upon it. Hence we now meet with many monuments of antiquity below ground, which formerly were undoubtedly above it.

Changes may naturally happen in the Strata of the Earth.

With regard to the ſtrata, it ſeems undeniable that they may be produced from natural cauſes. Clay will ſometimes be conſolidated into ſtone; flint, marble, and limeſtone, are all found to grow naturally in the earth; ſo that we cannot draw any concluſion from the order in which we now find them. Though we find a bed of ſhells, then, in the heart of a ſolid rock, this makes no difficulty in the theory of the earth; ſince we know that the rock hath by ſome natural cauſe been conſolidated around them. In fact, this is not ſo wonderful, as what is related by Mr. Price in his treatiſe of minerals, mines, &c. viz. That at the town of Redruth in Cornwall, "ſome labourers being put to clear and level the ſtreet for a pavement, they found a piece of hard ſtone in the ground, with abundance of common ſmall pins of braſs interſperſed in and throughout the ſtone, in ſuch manner and form, that all thoſe who ſaw it afterwards, were convinced it was not done artificially, but that the ſtone was formed and produced by petrifaction, ſubſequent to the time the pins were dropped into the ground. Doctor Plot, in his Natural Hiſtory of Staffordſhire, ſays, that near Newcaſtle under Lyne, there was found a ſtone with a man's ſkull, teeth and all, incloſed in it."—From theſe and other facts in ſome meaſure ſimilar, this author concludes, that "every earth or clay, in ſome places, may be converted into ſtone in proceſs of time, at ſuch a depth where it is undiſturbed by being never lacerated nor moleſted, and alſo were it abounds with an uncommon quantity of juices of a lapideſcent quality: but this property being extenuated or deſtroyed, the earthy ſtones may not improbably again return to their primitive clay. Thus we ſee ſome ſorts of ſtone, when dug out of the ground and expoſed to the air for a conſiderable time, do moulder again into earth, at leaſt in appearance; while others, of an earth-like quality, are indurated, and become more compact and durable by lying above ground."

No ſufficient Proof of extraordinary Changes on the Surface of the Earth.

With regard to the extraordinary changes which Mr. Buffon and others imagine to have taken place on the ſurface of the earth, they do not appear to have any ſolid foundation. Changes, no doubt, have happened in particular parts; new iſlands have been thrown up from the bottom of the ſea by the force of ſubterraneous fire, and others have been ſwallowed up. But theſe appear to be merely the effects of volcanoes, which are common in many parts of the world; and we are not warranted to conclude, becauſe we ſee a ſmall volcanic iſland ariſe, and another ſwallowed up, that this has been the caſe with the whole habitable world.

Volcanic Theory.

An imperfect theory hath indeed been ſuggeſted by Sir William Hamilton, Mr. Brydone, and others, concerning the uſe of volcanoes and ſubterraneous fires; from whence it might ſeem probable, though they do not indeed ſay ſo in direct terms, that all the dry land was originally thrown up from the bottom of the ſea by the force of theſe fires. Sir William Hamilton, in his letter to Doctor Maty, broaches this theory in the following words. "I am myſelf convinced, that the whole circuit, ſo far as I have examined, within the boundaries marked in the map, (extending at leaſt 50 Italian miles in length, and 30 in breadth where broadeſt), is wholly and totally the production of ſubterraneous fires; and that moſt probably the ſea formerly reached the mountains, that lie behind Capua and Caſerta, and are a continuation of the Appenines. If I may be allowed to compare ſmall things with great, I imagine the ſubterraneous fires to have worked in this country under the bottom of the ſea, as moles in a field, throwing up here and there a hillock; and that the matter thrown out of ſome of theſe hillocks formed into ſettled volcanoes, filling up the ſpace between the one and the other, has compoſed this part of the continent, and many of the iſlands adjoining.

"From the obſervations I have made upon Mount Ætna, Veſuvius, and the neighbourhood, I dare ſay, that, after a careful examination, moſt mountains that are, or have been, volcanoes, would be found to owe their exiſtence to ſubterraneous fire; the direct reverſe of what I find the commonly received opinion.—Nature, though varied, is certainly in general uniform in her operations; and I cannot conceive, that two ſuch conſiderable volcanoes as Ætna, and Veſuvius, ſhould have been formed otherwiſe than every other conſiderable volcano of the known world. I do not wonder that ſo little progreſs hath been made in the improvement of natural hiſtory, and particularly in that branch of it which regards the theory of the earth: nature acts ſlowly; it is difficult to catch her in the fact.

Bracini, however, in his account of the eruption of 1613, ſays, that he found many ſorts of ſea ſhells on Veſuvius after that eruption; and P. Ignatio, in his account of the ſame eruption, ſays, that he and his companions picked up many ſhells likewiſe at that time upon the mountain: this circumſtance would induce one to believe, that the water thrown out of Veſuvius during that formidable eruption, came from the ſea."

Inſufficiency of the Volcanic Theory.

This may ſerve to ſhew upon what grounds the volcanic theory ſtands; but though we ſhould admit it in its utmoſt extent, the theory of the earth can receive but very little aſſiſtance from it. Mr. Hamilton himſelf does not ſay that all the mountains have been volcanoes, or that all the ſoil throughout the different quarters of the world hath been thrown up from the bottom of the ſea. If therefore, there remains but one mountain in the whole world which never was a volcano, we ſhall be as much difficulted to account for the production of that one, as though there were ever ſo many; and at any rate our theory will be abſolutely uſeleſs, becauſe what will account for the origin of that mountain, will alſo account for the origin of others. If we go a ſtep beyond Mr. Hamilton, and ſay, that there are no mountains whatever that have not been originally volcanoes, but that all the dry land is the production of ſubterraneous fire, our difficulties are ſo far from being removed, that they are greatly increaſed. The lavas and volcanic aſhes, though in time they become covered with an exceedingly fertile ſoil, remain abſolutely barren for a great number of years, inſomuch that, by the adopters of the volcanic hypotheſis, the period at which Moſes fixes the creation is reckoned by far too late to have given time for covering the many lavas of Italy and Sicily with the depth of earth they juſt now have upon them. The whole world therefore muſt have remained for many ages in a ſtate of abſolute ſterility; and by what means vegetation firſt began, or in what corner of the world, remains to be inquired into.

Without entering further into the theories either of Mr. Hamilton, or any other perſon, it is eaſy to ſee, that all of them are inſufficient to ſolve the difficulties mentioned. The difficulties with regard to the ſtrata and ſhells ſeem inſolveable by any other means than ſuppoſing that there are in the terreſtrial matter ſeveral diſtinct powers, by which the ſtrata of any particular kind are occaſionally transformed into others; and that the ſhells and other marine bodies were originally depoſited on the ſurface by the deluge. The volcanic hypotheſis, by which ſome attempt to account for the appearance of theſe bodies, will in no ſhape anſwer the purpoſe. By the exploſions of a volcano, ſhells, mud, ſand, &c. might be indiſcriminately thrown up, and ſcattered irregularly about; but we could never find the large beds of ſhells which are frequently to be met with of a conſiderable extent, in different parts of the earth.

Notion of Chaos ought not to be adopted.

With regard to any degree of certainty, it is ſcarcely to be hoped for on this ſubject. The common notion of the earth's being originally a chaos, ſeems neither to have a foundation in reaſon, nor in the Moſaic account of the creation. It is ſurely inconſiſtent with the wiſdom aſcribed to the deity to think that he would create this viſible ſyſtem in confuſion, and then employ it to put itſelf in order. It ſeems more probable, that the earth was originally created with the inequalities of ſurface we ſee it have, and that the natural powers for preſerving it were afterwards ſuperadded. Thus, according to Moſes, the firſt natural agent created, or produced, by directing matter to move in a certain manner, was light. This, we know, was abſolutely neceſſary for the evaporation of the water which took place on the ſecond day. Moſes tells us, that the earth was originally covered with water: and we ſee a natural reaſon why it ſhould be ſo; namely, that the evaporation by the atmoſphere might more eaſily take place. When this was done, there being then no more occaſion for the waters in that diffuſed ſtate, they were commanded to retire into the place appointed for them, and thus formed the ocean. Whether this was done by the action of gravity then firſt taking place, or by any other means, we have it not in our power to know, nor will our ſpeculations on this ſubject probably be attended with much benefit. We ſee, however, that the Moſaic account of the creation is perfectly conſiſtent with itſelf, and free from thoſe difficulties with which other ſyſtems are clogged. It is impoſſible to ſhew, how, by any natural power, a confuſed maſs of matter, ſuch as the chaos of the ancient poets, of Drs. Burnet and Woodward, the hollow globe of Mr. Hutchinſon, the comet of Mr. Whiſton, or the vitrified matter of Mr. Buffon, could put itſelf in the order in which we ſee it. The ſacred hiſtorian ſimply tells us, that God created the heavens and the earth; that the heavens gave no light, and the earth was covered with water. He firſt commanded the light to ſhine, then the air to take up what quantity of water he thought proper for the purpoſes of vegetation. After this, the dry land was made to appear; and the different powers of vegetation already taken notice of, were given to it. Next the ſun and moon were created as ſubordinate agents, to do what we are told the deity had done before by his own immediate action, namely, *to divide the light from the darkneſs, &c.* Then followed the formation of animals and of man.

Moſaic Account of the Creation perfectly conſiſtent.

According to this account, it would appear, that what we call the *laws of nature*, were given to preſerve the earth in that ſhape which the Deity thought proper to give it originally by his own power: and by no means to form it in any particular way, much leſs to put it out of the form which he had already given it: and thus the world, according to the beſt accounts we have, is very little altered in its appearance; and, according to what we can judge, will continue unaltered for ever, unleſs the Creator thinks proper to interpoſe in ſuch a manner as to ſuperſede all the laws he hath given it, and change it into ſome other form.

Objections to the Moſaic Chronology.

From ſome obſervations of Mr. Hamilton and others, objections have been drawn, as hath been already mentioned, to the Moſaic chronology. Theſe objections are in ſubſtance as follows. In pits, and other natural and artificial openings of the ground, in the neighbourhood of Veſuvius and Ætna, ſeveral beds of lava have been diſcovered at conſiderable depths below each other. Theſe beds of lava in ſome places are covered with ſucceſſive ſtrata of vegetable mould. From this diſpoſition of materials, Sir William concludes, that the world muſt have been created at a much more remote period than is generally believed. The different ſtrata of lava found below ground, he obſerves, muſt have proceeded from an equal number of eruptions from the mountain; and, ſuch of them as are covered with vegetable ſoil, muſt have remained at leaſt 1000 years on the ſurface before they could acquire a ſoil ſufficient for the purpoſes of vegetation. Ten or twelve ſucceſſive ſtrata overlaid with ſoil, have already been diſcovered in the bowels of the earth; and it has been ſtrongly aſſerted, that, by digging deeper, many more might have been found. Now, allowing 1000 years for each ſtratum of lava, which the ſupporters of this theory affirm to be too little, the antiquity of the earth cannot be leſs than 12,000 years, which is more than double its age according to the Moſaic account.

The principal fact in this theory is, that 1000 years are neceſſary to the production of a ſoil ſufficient for the nouriſhment and growth of vegetables upon volcanic lavas. This notion is confirmed by a conjecture of the Canonico Recupero, that ſtreams of lava in Sicily have lain for centuries without acquiring a vegetable mould; and by ſome obſcure accounts, that theſe lavas have proceeded from eruptions of Ætna above 1000 years ago.

The correſpondence of theſe facts, related by Sir William himſelf, with his favourite notion that 1000 years are neceſſary for the production of a vegetable ſoil, we leave the reader to determine; and ſhall conclude with a few remarks of a different kind.

The appearance of a ſtratum of lava below ground, though not covered with vegetable ſoil, our author conſiders as demonſtrative evidence, that ſuch ſtratum formerly lay above the ſurface, and was thrown out by an eruption. This inference, however, ſeems not altogether juſt. Nothing, with propriety, receives the denomination of an eruption, unleſs when lava or other matter is vomited from the crater, or from ſome new opening made in the mountain. But it deſerves notice, that, in the environs of volcanoes, earthquakes are frequent. That theſe violent concuſſions are the genuine

produce

roduce of ſubterraneous fire expanding itſelf in every direction, nd making ſtrong efforts againſt every ſubſtance which reſiſts the atural tendency of its courſe, is a fact that cannot admit of doubt. t is no leſs certain, that theſe frequent concuſſions ſhake and diſ-ocate the internal parts of the earth. They cannot fail to ſhatter nd diſarrange the natural direction of the original ſtrata; and, of ourſe, they muſt give riſe to many ſubterraneous cavities and iſures. The nearer the great furnace, which confines the fury of e flames, the greater and more frequent will be the cavities. very earthquake occaſioned by a volcano is nothing elſe than an ffort of the burning matter to enlarge the boundaries by which it uſually limited. If the quantity of matter and degree of inflam-ation require a ſpace greatly ſuperior to the internal cavities, an ruption above the ſurface is an infallible conſequence. But when e quantity of matter, or the expanſive force occaſioned by the de-ree of inflammation, is inſufficient to raiſe the lava to the top of e mountain, an earthquake may be produced; and the lava, ithout ever appearing above the ſurface, may run below ground plentiful ſtreams, and fill up all the ſubterraneous cavities and hannels. Theſe internal ſtrata of lava may often lie ſo deep as to e below the level of the ſea. In this manner, we conceive it to e not only poſſible, but extremely probable, that beds of lava, aving no covering of vegetable ſoil, may be found at great depths, lthough they never were above the ſurface.

It is much more reaſonable to conclude, that lavas with a layer f ſoil were produced by eruptions, and once lay above the ſur-ace, till covered by the operation of time, or ſubſequent ſtreams rom the mouth of the volcano. But even in this caſe, the argu-ment is not altogether complete; for, as above remarked, earth-uakes, with which countries adjacent to volcanoes are perpe-ually infeſted, often ſink large tracts of land to great depths.

For the other parts of the theory of the earth which regard the ſitu-tion of the different parts of its ſurface with reſpect to each other; ts annual motion round the ſun as a planet; its diurnal motion round ts axis; and the different ſtrata whereof it is compoſed, as far as t hath been hitherto found practicable to penetrate into. See the rticles GEOGRAPHY, ASTRONOMY, &c.

EARTH *Worm*, in entomology. See LUMBRICUS.

DISSERTATION ON THE CAUSES AND EFFECTS OF EARTHQUAKES,

ACCORDING TO THE HYPOTHESES OF ANCIENT AND MODERN PHILOSOPHERS.

EARTHQUAKE, in natural hiſtory, a ſudden and violent concuſſion of the earth, generally attended with ſtrange noiſes un-der-ground or in the air; often deſtroying whole cities at once, hrowing down rocks, altering the courſe of rivers, and producing he moſt terrible devaſtations.

Though there is hardly any country known in which ſhocks of n earthquake have not at ſome time or other been felt, yet there re ſome much more ſubject to them than others.

What Countries are moſt ſubject to Earthquakes.

It hath been obſerved, that northern countries in general are eſs ſubject to earthquakes than thoſe ſituated near the equator, or in the ſouthern latitudes; but this does not hold univerſally. The ſlands of Japan, which are ſituated pretty far north, are neverthe-leſs exceedingly liable to theſe deſtructive phenomena. Iſlands in general, are alſo more ſubject to earthquakes than continents; but neither does this hold without exceptions. Some particular parts of continents, and ſome particular iſlands, are more ſubject to them than others lying in the neighbourhood, and differing very little from them in external appearance. Thus, Portugal is more ſubject to earthquakes than Spain, and the latter much more than France: Mexico and Peru more than the other coun-tries of America, and Jamaica more than the other Caribbee iſlands. Earthquakes are frequent, though not often violent, in Italy; but in Sicily they are often terribly deſtructive. Aſia Minor hath been remarkably ſubject to them from the remoteſt antiquity, and the city of Antioch in particular hath ſuffered more from earthquakes than any other in that country. The ſame phe-nomena are ſaid alſo to occur very frequently in the north-eaſtern extremities of Aſia, even in very high latitudes.

Hiſtory of their Phenomena incomplete.

Though there are no phenomena in nature more calculated to impreſs the human mind with terror, and conſequently to be well remembered and taken notice of, than earthquakes, yet the philoſophy of them is but lately arrived at any degree of perfec-tion; and even at this day, the hiſtory of earthquakes is very in-complete. The deſtruction occaſioned by them engroſſes the mind too much to admit of philoſophical ſpeculations at the time they happen: the ſame thing prevents the attentive conſideration of the alterations that take place in the atmoſphere after the earth-quake is over, and which might probably throw ſome light on the cauſes which produced them; and the ſuddenneſs of its coming on prevents an exact attention to thoſe ſlight appearances in the earth or air, which, if carefully obſerved, might ſerve as warnings to avoid the deſtruction.

Account of the Earthquakes in different Parts of the World.

The following deſcriptions of earthquakes have been verified by accounts of witneſſes of indiſputable veracity. In 1692, an earthquake happened in Jamaica, attended with almoſt all the terrible circumſtances above mentioned. In two minutes, it de-ſtroyed the town of Port Royal, at that time the capital of the iſland; and ſunk the houſes in a gulph 40 fathoms deep. It was attended with an hollow rumbling noiſe like that of thunder: the ſtreets roſe like the waves of the ſea, firſt lifting up the houſes, and then immediately throwing them down into deep pits. All the wells diſcharged their waters with the moſt violent agitation. The ſea burſt over its bounds, and deluged all that ſtood in its way. The fiſſures of the earth were in ſome places ſo great, that one of the ſtreets appeared twice as broad as formerly. In many places it opened and cloſed again; and continued this agitation for ſome time. Of theſe openings, great numbers might be ſeen at once. In ſome of them, the people were ſwallowed up at once: in others, the earth caught them by the middle, and cruſhed them to death; while others, more fortunate, were ſwallowed up in one chaſm, and thrown out alive by another. Other chaſms were large enough to ſwallow up whole ſtreets; and others, ſtill more formidable, ſpouted up immenſe quantities of water, drown-ing ſuch as the earthquake had ſpared. The whole was attended with ſtenches and offenſive ſmells, the noiſe of falling mountains at a diſtance, &c. and the ſky, in a minute's time, was turned dull and reddiſh, like a glowing oven. Yet, as great a ſufferer as Port Royal was, more houſes were left ſtanding therein, than on the whole iſland beſide.

Scarce a planting houſe, or ſugar houſe, was left ſtanding in all Jamaica. A great part of them were ſwallowed up, houſes, peo-ple, trees, and all, in one gap: in lieu of which, afterwards ap-peared great pools of water; which, when dried up, left nothing but ſand, without any mark that ever tree or plant had grown thereon. The ſhock was ſo violent, that it threw people down on their knees or their faces as they were running about for ſhelter. Several houſes were ſhuffled ſome yards out of their places, and yet continued ſtanding. One Hopkins had his plantation removed half a mile from the place where it ſtood, without any conſidera-ble alteration. All the wells in the iſland, as well as thoſe of Port Royal, from one fathom to ſix or ſeven deep, threw their water out at the top with great violence. About 12 miles from the ſea, the earth gaped and ſpouted out, with a prodigious force, vaſt quantities of water into the air: yet the greateſt violences were among the mountains and rocks; and it is a general opinion that the nearer the mountains, the greater the ſhock; and that the cauſe thereof lay among them. Moſt of the rivers were ſtopped up 24 hours, by the falling of the mountains; till, ſwelling up, they made themſelves new tracks and channels; tearing up, in their paſſage, trees, &c. After the great ſhock, thoſe people who eſcaped got on board ſhips in the harbour, where many con-tinued above two months; the ſhocks all that time being ſo vio-lent, and coming ſo thick, ſometimes two or three in an hour, ac-companied with frightful noiſes like a ruffling wind, or a hollow rumbling thunder, with brimſtone-blaſts, that they durſt not come aſhore. The conſequence of the earthquake was a general ſick-neſs, from the noiſome vapours belched forth, which ſwept away above 3000 perſons.

A ſtill more terrible account, if poſſible, is that given by Kir-cher, of the earthquake which happened in Calabria in the year 1638. This inſtance is an exception to the ſecond general poſi-tion above laid down. In Italy, there had been an eruption of Mount Veſuvius, five years before; and in Sicily there had been an eruption of Ætna, only two years before this earthquake. The event, however, plainly ſhewed, that the cauſe of the earth-quake, whatever it was, had a connection not only with Mount Ætna, which lies in the neighbourhood, but alſo with the volca-no of Stromboli, which is 60 miles diſtant. "On the 24th of March, (ſays Kircher,) we lanched (in a ſmall boat) from the har-bour of Meſſina in Sicily, and arrived the ſame day at the pro-montary of Pelorus. Our deſtination was for the city of Eu-phemia in Calabria; but on account of the weather, we were obliged to continue three days at Pelorus. At length, wearied with the delay, we reſolved to proſecute our voyage; and, although the ſea ſeemed more than uſually agitated, yet we ventured for-ward. The gulph of Charibdis, which we approached, ſeemed whirled round in ſuch a manner as to form a vaſt hollow, verging to a point in the centre. Proceeding onward, and turning my eyes to Mount Ætna, I ſaw it caſt forth large volumes of ſmoak, of mountainous ſizes, which entirely covered the iſland, and blotted out even the ſhores from my view. This, together with the dreadful noiſe, and the ſulphureous ſtench, which was ſtrongly perceived, filled me with apprehenſions, that ſome more dreadful calamity was impending. The ſea itſelf ſeemed to wear a very unuſual appearance; thoſe who have ſeen a lake in a violent ſhower of rain all covered over with bubbles, will have ſome idea of its agitation. My ſurpriſe was ſtill increaſed by the calmneſs and ſerenity of the weather; not a breeze, not a cloud, which might be ſuppoſed to put all nature thus into motion. I there-fore warned my companions, that an earthquake was approaching; and, after ſome time, making for the ſhore with all poſſible dili-gence, we landed at Tropæa. But we had ſcarce arrived at the Jeſuits college in that city, when our ears were ſtunned with an horrid ſound, reſembling that of an infinite number of chariot driven fiercely forward, the wheels rattling, and the thongs cracking. Soon after this, a moſt dreadful earthquake enſued; ſo that the whole track upon which we ſtood ſeemed to vibrate, as if we were in the ſcale of a balance that continued wavering. This motion, however, ſoon grew more violent; and being no longer able to keep my legs, I was thrown proſtrate upon the ground. After ſome time, however, finding that I remained unhurt amidſt the general concuſſion, I reſolved to venture for ſafety; and running as faſt as I could, reached the ſhore. I did not ſearch long here, till I found the boat in which I had landed, and my companions alſo. Leaving this ſeat of deſolation, we proſecuted our voyage along the coaſts; and the next day came to Rochetta, where we landed, although the earth ſtill continued in violent agitations. But we were ſcarce arrived at our inn, when we were once more obliged to return to our boat; and in about half an hour, we ſaw the greateſt part of the town, and the inn at which we had ſet up, daſhed to the ground, and burying all its inhabitants beneath its ruins. Proceeding onward in our little veſſel, we at length landed at Lopizium, a caſtle mid-way between Tropæa and Euphemia the city to which we were bound. Here, wherever I turned my eyes, nothing but ſcenes of ruin and horror appeared; towns and caſtles levelled to the ground: Stromboli, though at 60 miles diſtance, belching forth flames in an unuſual manner, and with a noiſe which I could diſtinctly hear. But my attention was quickly turned from more remote, to contiguous, danger. The rumbling ſound of an approaching earthquake, which by this time we were grown acquainted with, alarmed us for the conſequences. It every moment ſeemed to grow louder, and to approach more near. The place on which we ſtood now began to ſhake moſt dreadfully; ſo that, being unable to ſtand, my companions and I caught hold of whatever ſhrub grew next us, and ſupported ourſelves in that manner. After ſome time, the violent paroxyſm ceaſing, we again ſtood up, in order to proſecute our voyage to Euphemia, which lay within ſight. In the mean time, while we were preparing for this purpoſe, I turned my eyes towards the city; but could ſee only a frightful dark cloud, that ſeemed to reſt upon the place. This the more ſurpriſed us, as the weather was ſo very ſerene. We waited, therefore, till the cloud was paſſed away; then turning to look for the city, it was totally ſunk; and nothing but a diſmal and putrid lake was to be ſeen where it ſtood."

Of the Earthquake in Sicily in 1693.

In 1693 an earthquake happened in Sicily, which may juſtly be accounted one of the moſt terrible of which we have an account. It ſhook the whole iſland: and not only that, but Naples and Malta ſhared in the ſhock. It was impoſſible for any body, in this country, to keep on their legs on the dancing earth; nay, thoſe that lay on the ground were toſſed from ſide to ſide, as on a rolling billow: high walls leaped from their foundations ſeveral paces, &c. The miſchief it did is amazing: almoſt all the buildings in the countries were thrown down. Fifty four cities and towns, beſide an incredible number of villages, were either deſtroyed or greatly damaged. We ſhall only inſtance the fate of Catania, one of the moſt famous, ancient, and flouriſhing cities in the kingdom; the reſidence of ſeveral monarchs, and an univerſity. This once famous city had the greateſt ſhare in the tragedy. Father Anthon. Serrovita, being on his way thither, and at the diſtance of a few miles, obſerved a black cloud like night hovering over the city; and there aroſe from the mouth of Montgibello, great ſpires of flame, which ſpread all around. The ſea all of a ſudden began to roar, and riſe in billows; and there was a blow, as if all the artillery in the world had been at once diſcharged. The birds flew about aſtoniſhed; the cattle in the fields ran crying, &c. His and his companions horſes ſtopped ſhort, trembling; ſo that they were forced to alight. They were no ſooner off, than they were lifted from the ground above two palms; when, caſting his eyes towards Catania, he with amazement ſaw nothing but a thick cloud of duſt in the air. This was the ſcene of their calamity: for of the magnificent Catania, there was not the leaſt footſtep to be ſeen. S. Bonajutus aſſures us, that of 18900 inhabitants, 18000 periſhed therein.

Phenomena of the Great Earthquake, November 1, 1755.

The great earthquake, however, which happened on the 1ſt of November 1755, affords the cleareſt example of all the phenomena above-mentioned; early in the morning, a thick fog aroſe, which was ſoon diſſipated by the heat of the ſun; no wind was ſtirring, the ſea was calm, and the weather as warm as in June or July in this country. At 35 minutes after nine, without the leaſt warning, except a rumbling noiſe not unlike the artificial thunder in our theatres, a moſt dreadful earthquake ſhook, by ſhort but quick vibrations, the foundations of all the city, ſo that many buildings inſtantly fell. Then, with a ſcarce perceptible pauſe, the nature of the motion was changed, and the houſes were toſſed from ſide to ſide, with a motion like that of a waggon violently driven over rough ſtones. This ſecond ſhock laid almoſt the whole city in ruins, with prodigious ſlaughter of the people. The earthquake laſted in all about ſix minutes. At the moment of its beginning, ſome perſons on the river, near a mile from the city, heard their boat make a noiſe as if it had run aground, though they were then in deep water; and at the ſame time they ſaw the houſes falling on both ſides of the river. The bed of the river Tagus was, in many places, raiſed to its ſurface. Ships were drove from their anchors, and joſtled together with great violence; nor did their maſters know whether they were afloat or aground. A large new quay ſunk to an unfathomable depth, with ſeveral hundreds of people who were upon it; nor was one of the dead bodies ever found. The bar was at firſt ſeen dry from ſhore to ſhore; but ſuddenly the ſea came rolling in like a mountain; and about Belem Caſtle, the water roſe 50 feet almoſt in an inſtant. About noon, there was another ſhock; when the walls of ſeveral houſes that yet remained, were ſeen to open from top to bottom more than a quarter of a yard, and afterwards cloſed again ſo exactly that ſcarce any mark of the injury was left.

This ſhock was felt the ſame day at Madrid, Seville and Oporto, Cadiz and Gibraltar; alſo, at Arzilla, Morocco, and other places on the African coaſt, and in the iſlands of Madeira, Barbadoes, and Antigua, and its effects reached Norway, Sweden, Germany, Holland, Italy and Switzerland; nor were England, Scotland, or Ireland, free from its convulſions.—In France ſhocks were perceived in ſeveral places, as at Bayonne, Bourdeaux and Lyons. Commotions of the waters were alſo obſerved at Angouleme, Beville, Havre de Grace, &c. but not attended with the remarkable circumſtances abovementioned.

Hypotheſes concerning the Cauſes of Earthquakes.

Theſe are the phenomena which attended this moſt remarkable earthquake in many parts of the world. We have accounts of its effects over the ſpace of 4,000,000 ſquare miles, and undoubtedly it would be felt in a ſmall degree much farther to the ſouthward than we can have any account of. To explain the phenomena of earthquakes, various hypotheſes have been invented. Till lately, the hypotheſis of the modern philoſophers was much the ſame with that of the ancients. Anaxagoras ſuppoſed the cauſe of earthquakes to be ſubterraneous clouds burſting out into lightning, which ſhook the vaults that confined them. Others imagined, that the arches, which had been weakened by continual ſubterraneous fires, at length fell in: Others derived theſe accidents from the rarefied ſteam of waters, heated by ſome neighbouring fires; and ſome, among whom was Epicurus, and ſeveral of the Peripatetic ſchool, aſcribed theſe terrible accidents to the ignition of certain inflammable exhalations.

This laſt hypotheſis has been adopted by many of the moſt celebrated moderns, as Gaſſendus, Kircher, Schottus, Varenius, Des Cartes, Du Hamel, Honorius Fabri, &c. The philoſopher laſt mentioned indeed ſuppoſed, that waters prodigiouſly rarefied by heat might ſometimes occaſion earthquakes. The others ſuppoſed, as their hypotheſis neceſſarily requires, that there are many vaſt cavities underground which have a communication with one another; ſome of which abound with waters; others with vapours and exhalations, ariſing from inflammable ſubſtances, as nitre, bitumen, ſulphur, &c. Theſe combuſtible exhalations they ſuppoſed to be kindled by a ſubterraneous ſpark, or by ſome active flame gliding through a narrow fiſſure from without, or by the fermentation of ſome mixture; and when this happened, they muſt neceſſarily produce pulſes, tremors, and ruptures at the ſurface, according to the number and diverſity of the cavities, and the quantity and activity of the inflammable matter. This hypotheſis is illuſtrated by a variety of experiments, ſuch as mixtures of iron-filings and brimſtone buried in the earth, gun-powder confined in pits, &c. by all which a ſhaking of the earth will be produced.

Dr. Woodward ſuggeſts another hypotheſis. He ſuppoſes that the ſubterraneous heat or fire, which is continually elevating water out of the abyſs, which, according to him, occupies the centre of the earth, to furniſh rain, dew, ſprings, and rivers, may be ſtopped in ſome particular part. When this obſtruction happens, the heat cauſes a great ſwelling and commotion in the waters of the abyſs: and at the ſame time, making the like effort againſt the ſuperincumbent earth, that agitation and concuſſion of it is occaſioned what we call an earthquake.

Mr. Amontons of the Royal Academy of Sciences, ſuggeſts an hypotheſis entirely different from any of the abovementioned ones. According to the received philoſophical principles, which ſuppoſe the atmoſphere to be about 45 miles high, and that the denſity of the air increaſes in proportion to the abſolute height of the ſuperincumbent column of fluid; it is ſhewn, that at the depth of 43,528 fathoms below the ſurface of the earth, air is but one fourth lighter than mercury. Now, this depth of 43,528 fathoms is only a 74th part of the ſemi-diameter of the earth. And the vaſt ſphere beyond this depth, in diameter 6,451,538 fathoms, may probably be only filled with air; which will be here greatly condenſed, and much heavier than the heavieſt bodies we know of in nature. But it is found by experiment, that the more air is compreſſed, the more does the ſame degree of heat increaſe its ſpring, and the more capable does it render it of a violent effect; and that, for inſtance, the degree of heat of boiling water increaſes the ſpring of the air above what it has in its natural ſtate, in our climate, by a quantity equal to a third of the weight wherewith it is preſſed.

Whence we may conclude, that a degree of heat, which on the ſurface of the earth will only have a moderate effect, may be capable of a very violent one below. And as we are aſſured, that there are in nature degrees of heat much more conſiderable than that of boiling water, it is very poſſible there may be ſome, whoſe violence, further aſſiſted by the exceeding weight of the air, may be more than ſufficient to break and overturn this ſolid orb of 43,528 fathoms; whoſe weight, compared to that of the included air, would be but a trifle.

All theſe Hypotheſes rejected by Dr. Stukely.

Though none of theſe hypotheſes were ſufficient for explaining the phenomena of earthquakes in a ſatisfactory manner, one or other of them continued to be adopted by almoſt all philoſophers, till the year 1749. In the month of March that year, an earthquake was felt at London and ſeveral other places in Britain. Dr. Stukely, who had been much engaged in electrical experiments, began to ſuſpect that phenomena of this kind ought to be attributed not to vapours or fermentations generated in the bowels of the earth, but to electricity. In a paper publiſhed by him on this ſubject, he rejects all the above-mentioned hypotheſes for the following reaſons.

1. That there is no evidence of any remarkable cavernous ſtructure of the earth; but that, on the contrary, there is rather reaſon to preſume that it is in a great meaſure ſolid, ſo as to leave little room for internal changes and fermentations within its ſubſtance; nor do coal-pits, he ſays, when on fire, ever produce any thing reſembling an earthquake.

2. In the earthquake at London, in March 1749, there was no ſuch thing as fire, vapour, ſmoke, ſmell, or an eruption of any kind obſerved, though the ſhock affected a circuit of 30 miles in diameter. This conſideration alone of the extent of ſurface ſhaken by an earthquake, he thought ſufficient to overthrow the ſuppoſition of its being owing to the expanſion of any ſubterraneous vapours. For as ſmall fire-balls burſting in the air propagate a ſulphureous ſmell to the diſtance of ſeveral miles, it cannot be ſuppoſed, that ſo immenſe a force acting inſtantaneouſly on that compaſs of ground ſhould never break the ſurface of it, nor become diſcoverable either to the ſight or the ſmell: beſides, that the operation of ſuch a fermentation would be many days in continuance, and the evaporation of ſo much inflammable matter would require a long ſpace of time. That ſuch an effect, therefore, ſhould be produced inſtantaneouſly, can be accounted for by electricity only; which acknowledges no ſenſible tranſition of time, no bounds.

3. If vapours, and ſubterraneous fermentations, exploſions, and eruptions, were the cauſe of earthquakes, they would abſolutely ruin the whole ſyſtem of ſprings and fountains, wherever they had once been; which is contrary to fact, even when they have been frequently repeated. Even in the earthquake in Aſia Minor, A. D. 17, which deſtroyed 13 great cities, and ſhook a maſs of earth 300 miles in diameter, nothing ſuffered but the cities; neither the ſprings nor the face of the country being injured, which indeed remains the ſame to this day.

4. That any ſubterraneous power ſufficient to move 30 miles in diameter, as in the earthquake which happened at London, muſt be lodged at leaſt 15 or 20 miles below the ſurface; and therefore muſt move an invented cone of ſolid earth, the baſe of which is 30 miles in diameter, and the axis 15 or 20: an effect impoſſible to any natural power whatever, except electricity. So in Aſia Minor, ſuch a cone muſt have been 300 miles in the diameter of the baſe, and 200 in the axis; which not all the gun-powder that has been made ſince the invention of it, much leſs any vapours generated ſo far below the ſurface, could poſſibly effect.

5. A ſubterraneous exploſion will not account for the manner in which ſhips, far from land, are effected during an earthquake; which ſeem as if they ſtruck upon a rock, or as if ſomething thumped againſt the bottoms. Even the fiſhes are affected. A ſubterraneous exploſion could only produce a gradual ſwell, and not give ſo quick an impulſe to the water as would make it feel like a ſtone.

His Method of Accounting for Eearthquakes.

From comparing theſe circumſtances, the Doctor ſays, he had always thought that an earthquake was a ſhock of the ſame kind as thoſe which commonly occur in electrical experiments. And this hypotheſis was confirmed by the phenomena attending earthquakes: particularly thoſe of 1749 and 1750, which gave riſe to his publication.

The weather, for five or ſix months before, had been uncommonly warm; the wind ſouth and ſouth-weſt, without rain; ſo that the earth muſt have been in a ſtate peculiarly ready for an electrical ſhock. The flat country of Lincolnſhire had been under an exceeding great drought. The uncommonneſs of the firſt of theſe circumſtances, he remarks, is the reaſon why earthquakes are leſs frequently experienced in the northern than in the ſouthern regions of the world, where the warmth and dryneſs of the air, ſo neceſſary to electricity, are more uſual; and the latter ſhows how fit the dry ſurface was for an electrical vibration; and (which is of great importance) that earthquakes reach but little below the ſurface of the earth.

Before the earthquake at London, all vegetables had been uncommonly forward. And electricity is well known to quicken vegetation. The aurora borealis had been frequent about that time; and, juſt before the earthquake, had been twice repeated in ſuch colours as had never been ſeen before. It had alſo removed ſoutherly, contrary to what is common in England; ſo that the Italians, and thoſe among whom earthquakes were frequent, actually foretold the earthquake. The year had been remarkable for fire-balls, lightning, and coruſcations; and theſe are rightly judged to be meteors of an electrical nature.

In theſe circumſtances of the earth and air, nothing, he ſays, is wanting to produce an earthquake, but the touch of ſome non-electric body; which muſt neceſſarily be had *ab extra*, from the region of the air or atmoſphere. Hence he infers, that, if a non-electric cloud diſcharge its contents upon any part of the earth, in that highly electrical ſtate, an earthquake muſt neceſſarily enſue. As the diſcharge from an excited tube produces a commotion in the human body, ſo the diſcharge of electric matter from the compaſs of many miles of ſolid earth, muſt needs be an earthquake; and the ſnap from the contact, the horrid uncouth noiſe attending it, ſufficiently point out what ſort of a motion it is: not a convulſion of the bowels of the earth; but an uniform vibration along its ſurface, like that of a muſical ſtring or a glaſs when rubbed on the edge with one's finger.

The circumſtance of earthquakes chiefly affecting the ſea-coaſt, places along rivers, (and, adds Doctor Prieſtley, eminences) is a farther argument of their being electrical phenomena. This is illuſtrated by a particular account of the direction in which the earthquake was conveyed.

The laſt argument he uſes is taken from the effects which it had on perſons of weak conſtitutions, who were, for a day or two after it happened, troubled with pains in the back, rhuematiſms, hyſterics, and nervous diſorders; juſt in the ſame manner as they would have been after an actual electrification: to ſome theſe diſorders proved fatal.

As to the manner in which the earth and atmoſphere are put into this ſtate, which prepares them to receive ſuch a ſhock, and whence the electric matter comes, the Doctor does not pretend to determine; but thinks it as difficult to be accounted for, as magnetiſm, gravitation, and many other ſecrets of nature.

Hypotheſis of Doctor Prieſtley.

Dr. Prieſtley, in his Hiſt. of Electricity, obſerves upon theſe theories, that a more probable hypotheſis may perhaps be formed out of both of them. "Suppoſe (ſays he) the electric matter to be, ſome way or other, accumulated on one part of the ſurface of the earth, and, on account of the dryneſs of the ſeaſon, not eaſily to diffuſe itſelf; it may, as Signior Beccaria ſuppoſes, force its way into the higher regions of the air, forming clouds in its paſſage, out of the vapours which float in the atmoſphere, and occaſion a ſudden ſhower, which may further promote the paſſage of the fluid. The whole ſurface, thus unloaded, will receive a concuſſion, like any other conducting ſubſtance, on parting with, or receiving, a quantity of the electric fluid. The ruſhing noiſe will likewiſe ſweep over the whole extent of the country. And, upon this ſuppoſition alſo, the fluid, in its diſcharge from the country, will naturally follow the courſe of the rivers, and alſo take the advantage of any eminences to facilitate its aſcent into the higher regions of the air."

The Doctor, making experiments with a battery on the paſſage of the electrical fluid over different conducting ſubſtances, and among theſe, over water; and remarking a reſemblance between its paſſage over the ſurface of the water, and that which Doctor Stukeley ſuppoſed to ſweep the ſurface of the earth, when a conſiderable quantity of it is diſcharged to the clouds during an earthquake; immediately ſuſpected that the water over which it paſſed, and which was viſibly thrown into a tremulous motion, muſt receive a concuſſion reſembling that which is given to the waves of the ſea on ſuch an occaſion.

To try this, he himſelf and others preſent put their hands into the water at the time that the electrical flaſh paſſed over its ſurface; and they felt a ſudden concuſſion given to them, exactly like that which is ſuppoſed to affect ſhips at ſea during an earthquake. This percuſſion was felt in various parts of the water, but was ſtrongeſt near the place where the exploſion was made. The ſame experiment, with a little variation, being afterwards made with a ſingle jar, at ſome diſtance below the ſurface of the water, produced the like effect, though in a weaker degree. "This ſimilarity in the effect," the Doctor obſerves, "is a conſiderable evidence of a ſimilarity in the cauſe."

"Pleaſed with this reſemblance of the earthquake, (ſays he) I endeavoured to imitate that great natural phenomenon in other reſpects: and, it being froſty weather, I took a plate of ice, and placed two ſticks, about three inches high, on their ends, ſo that they would juſt ſtand with eaſe; and upon another part of the ice, I placed a bottle, from the cork of which was ſuſpended a braſs ball with a fine thread. Then, making the electrical flaſh paſs over the furface of the ice, which it did with a very loud report, the nearer pillar fell down, while the more remote ſtood; and the ball, which had hung nearly ſtill, immediately began to make vibrations about an inch in length, and nearly in a right line from the place of the flaſh."

"I afterwards diverſified this apparatus, erecting more pillars, and ſuſpending more pendulums, &c. ſometimes upon bladders ſtretched on the mouth of open veſſels, and other times upon wet boards ſwimming in a veſſel of water. This laſt method ſeemed to anſwer the beſt of any: for the board repreſenting the earth, and the water the ſea, the phenomena of them both during an earthquake may be imitated at the ſame time; pillars, &c. being erected on the board, and the electric flaſh being made to paſs either over the board, over the water, or over them both."

Deficiency of all theſe Hypotheſes.

Theſe three hypotheſes concerning the cauſe of earthquakes, though ſomewhat differing from one another, yet agree in the main; but, if a particular ſolution of the phenomena is required, every one of them will be found deficient.

If, according to Dr. Stukeley's hypotheſis, the electric matter is lodged only on the ſurface of the earth, or but at a ſmall depth below; how are we to account for thoſe violent effects which often take place in the bowels of the earth. In the earthquake at Liſbon, a large quay ſunk to an unfathomable depth. We are certain, that the cauſe of the earthquake muſt have been below this depth however great it was, and have opened the earth for an immenſe way downwards. At the ſame time an hill in Barbary clave aſunder, and the two halves of it fell different ways. This ſhews, that the cauſe of the earthquake operated not on the ſurface of the hill, but on the ſolid foundation and contents of it; nor can it be explained by any ſuperficial action whatever. From what the miners at Eyam bridge in Derbyſhire obſerved, it is alſo evident, that the ſhock was felt at the depth of 396 feet below the ſurface of the ground more than at the ſurface itſelf; and conſeduently there is all the reaſon in the world to think that the cauſe lay at a depth vaſtly greater.

Again, though the earthquake at London was ſuppoſed to begin with a black cloud and ſhower; yet in that of 1755, the effects of which were incomparably greater, the air was calm and ſerene almoſt in every place where it was felt. It doth not appear that there is at any time a conſiderable difference between the electricity of the atmoſphere and that of the earth, or indeed that there can be ſo. For, if the earth is electrified *plus*, and the atmoſphere *minus*, there are innumerable points on the ſurface of the earth which muſt be imperceptibly drawing off the ſuperfluous electric matter into the air. The vapours alſo, with which the atmoſphere abounds, would always be ready in the ſame ſervice; and thus thunder and lightning might indeed ſometimes be produced, but not earthquakes. But laſtly, neither the air nor the earth does always ſhow any remarkable ſigns of electricity before earthquakes happen. For, the ſummer before the earthquake at Mancheſter in 1777, there had ſcarce been any thunder, lightning, or other ſigns of electricity in the atmoſphere, and vegetation had been extremely backward; and, according to the beſt accounts, the weather continued remarkably fine. For theſe reaſons, Dr. Stukeley's hypotheſis ſeems not to be ſatisfactory.

Dr. Prieſtley's hypotheſis is liable to the ſame objections with that of Dr. Stukeley: for any ſuperficial operation will never account for thoſe effects above mentioned, which take at great depths below the ſurface. His experiment cannot be admitted as any way concluſive with regard to the cauſe of earthquakes, becauſe no quantity of electric fire is ſeen to paſs over the earth and ſea, like the flaſh attending the exploſion of an electric battery; and the force of his earthquake, (being but juſt able to throw down a ſtick that could hardly ſtand by itſelf) ſeems by far too little. The utmoſt force of electricity which man can raiſe, is indeed very trifling, when compared with the great operations of nature: but it is certain, that the force of an electric battery, is by no means contemptible; was its whole power to be employed in producing an imitation of an earthquake, it certainly would do much more than throw down a ſmall ſtick. The bad ſucceſs of this experiment therefore ſhows, that the doctor's theory is erroneous: for, almoſt the whole of his electric power was ſpent another way; and we cannot ſuppoſe, that any conſiderable part of the force which produces earthquakes is ſpent any other way than in the very production of the earthquake itſelf.

Principles on which the Phenomena may be explained.

If it is attempted to give an explanation of the phenomena of earthquakes, which ſhall be free from the objections abovementioned, and from all others, it will be neceſſary, in the firſt place, to conſider thoſe parts of the ſyſtem of nature which ſeem to be moſt affected during the terrible phenomena we treat of. Theſe parts are, the air, the ſolid earth, and the water. Of theſe the two former are electrics *per ſe*; the latter is a conductor, though a bad on. Hence it follows:

1. That in proportion to the quantity of earth which is mixed with any quantity of water, that mixture will approach nearer to the nature of an electric *per ſe* and *vice verſa*.

2. It alſo follows, that whatever quantity of electricity is communicated to the ſolid earth, will be quickly taken off from it by the water which is mixed with it, in the ſame manner that the electric matter is carried off from an excited globe by a metallic conductor.

3. The whole earth is moiſt, and therefore in ſome degree a conductor. Nevertheleſs, as earth of all kinds, when perfectly dry, is found to be an electric, capable of receiving a charge like glaſs, it is therefore poſſible, that the electric power of the earth may be excited to ſuch a degree, that the moiſture of the ſolid parts cannot eaſily contain the quantity of electricity communicated.

4. In this caſe, the earth muſt either give undoubted ſigns of its being excited in the ſame manner that other excited electrics do, or the electricity muſt be diſcharged ſomewhere elſe.

5. To receive any ſuperfluous quantity of electric matter that may be communicated to the ſolid earth, the waters of the ocean are always ready. Theſe, being a much better conductor than earth, muſt be a principal mean of preſerving the equilibrium of electricity in the different parts of the earth; and hence we ſee a natural reaſon why the waters of the ocean ſhould cover ſo large a proportion of the globe as they are known to do.

6. It is known, that fire is alſo a conductor of electricity. Therefore, wherever a quantity of electric matter is collected in any part of the ſolid earth, if it can neither be conveniently received by the moiſture which the earth naturally contains, nor by the ocean in its neighhourhood, it will diſcharge itſelf by any volcano that happens to be in an active ſtate, near the place where that collection of electric matter is.

7. It is alſo found, that the electric fluid, being violently reſiſted by the ſuperincumbent atmoſphere, hath always a tendency to diſcharge itſelf in thoſe places where that reſiſtance is leaſt. The tops of very high mountains, therefore, where the weight of the atmoſphere is greatly diminiſhed, will alſo afford a ready paſſage for the electric fluid when it is collected in very great quantity in the bowels of the earth.

8. If, from ſome natural cauſes, the electric matter ſhall happen to be collected in the bowels of the earth in any particular place; and at the ſame time ſuch obſtacles are thrown in its way, that it can neither diſcharge itſelf into the ocean, nor into the atmoſphere, by the tops of high mountains, nor by the more open paſſages of volcanoes; the moſt terrible conſequences muſt enſue: the matter being pent up, and the cauſe by which it is collected continuing ſtill to act, its impulſe becomes at laſt irreſiſtible. It then flies againſt every obſtacle with inconceivable violence. It breaks out in all thoſe places where there is the leaſt reſiſtance, and therefore the ſhock is directed a great number of different ways at once.

The height of the mountains renders them the objects of the deſtructive force of this fluid much more than any buildings whatever. Hence they are often rent, and rocks thrown down from them. The water contained in the ſolid parts of the earth, being a conductor of electricity, becomes overloaded with it; and, when it can receive no more, is forced to yield to the impulſe of the reſt, and therefore is thrown out of the earth in great quantities. For the ſame reaſon, the waters on the ſurface of the earth are moſt violently agitated. The ſmall quantities contained in wells are thrown out at the tops of them: the rivers and lakes, which contain too great a quantity of water to be thrown off from the earth, riſe in billows: the ocean itſelf, receiving more electric matter than can immediately be diſperſed through the whole body of water, or evaporate into the atmoſphere, retreats from the land, and is raiſed in vaſt mountains. The ſolid earth itſelf, being unable either to conduct the fluid quietly to thoſe parts where it is wanted, or to retain it, is violently ſhaken, or rent in multitudes of places; and this not only on the ſurface, but to great depths. The electricity being now in ſome meaſure diſcharged from the earth, the ocean ruſhes forward with fury to diſcharge in its turn the exceſs of electric matter it juſt before received from the earth. If there are volcanoes in the neighbourhood, the violent diſcharge of electricity is ſure to manifeſt itſelf by ſetting them in a flame; and thus, till the equilibrium is reſtored, all nature ſeems to be threatened with diſſolution. Even in thoſe places where the force of the electric fluid is not able to ſhake the ſolid parts of the earth, it manifeſts its power by agitating the waters in the manner above deſcribed. Water being a much better conductor of electricity than earth, this ſubtile fluid, as ſoon as it can get out from the ſolid earth, flies to the water. The conſequence is, that the water immediately ſwells up, and is attracted by whatever part of the earth has leſs electricity than itſelf. Hence thoſe ſtrange irregular motions of the waters in different places, ſo particularly obſerved at the time of the earthquake at Liſbon; and which it ſeems impoſſible to account for from any other cauſe than an immediate diſcharge of electric matter from the earth into them.

9. As it is impoſſible that any part of the earth can be electrified without communicating a proportionable ſhare of electricity to the animals that live upon it, and have a conſtant communication with it, it thence follows, that there can be no conſiderable commotion in the electric matter lodged in the bowels of the earth, without affecting that which is contained in the bodies of the animals. Hence the brutes, who ſeem to be more ſenſible of ſuch commotions than we, run about, and ſhew ſigns of fear, before the earthquake comes on; and hence the giddineſs, ſickneſs, &c. which the human race are ſubject to during the time of the ſhock, even though they do not feel it, as was the caſe at Gibraltar.

10. As the atmoſphere hath a communication with the earth, it is ſcarce to be ſuppoſed that the earth can, for any length of time, contain a conſiderable quantity of electric matter, without communicating to the atmoſphere a proportionable quantity. Before an earthquake, therefore, we muſt ſuppoſe the electricity

of the earth and air to be in perfect equilibrio. Hence the weather is ſerene, there is no wind, nor any other ſign in the atmoſphere, of the terrible cataſtrophe that is about to enſue. But the moment the diſcharge is made from the earth, the equilibrium between the terreſtrial and atmoſpherical electricity is broken; the air either begins to receive the fluid from the earth, or the earth from the air. As there is not then time for the collection of thunder-clouds by which the electricity may be brought down in ſudden flaſhes of lightning, the fluid breaks through the ſubſtance of the air itſelf with diſmal and horrid noiſes, which always accompany an earthquake. That this is the caſe, ſeems highly probable from an experiment of M. de Romas, when, having brought down a vaſt quantity of electric matter from the clouds by means of a kite, he heard the noiſe it made in the air, like the continual blowing of a ſmall forge bellows. In general, there is a conſiderable change of weather takes place at the time of an earthquake, though not always. In the earthquake which happened in England in 1777, there was no remarkable change of weather there; but, ſoon after, there was a great deal of thunder and lightning in the ſouthern parts of Scotland: which ſeems to indicate, that the electric fluid diſcharged from the earth in England had taken its courſe northward, and produced the phenomena before mentioned in Scotland.

Ultimate Cauſe of all the Phenomena.

Having thus explained all the phenomena attending earthquakes, it remains only to ſhow by what means the equilibrium of electricity can be broken in the bowels of the earth in ſuch a manner as to produce theſe phenomena.

The ultimate cauſe of this is, that the warmth of the ſun moſt neceſſarily bring down to the earth much greater quantities of electric matter in the regions within the tropics, than in the northern and ſouthern climates. It is impoſſible, that there can be a perpetual accumulation of electricity in one part of the earth, unleſs there is a paſſage for it into the atmoſphere through ſome other. Hence, if the electric matter deſcends from the air into one place of the earth, it muſt neceſſarily aſcend from the earth into the air in ſome other place. There muſt be therefore a continual current of electricity through the bowels of the earth, beginning at the equator, and extending northward and ſouthward to both poles. While this current has a free paſſage from the earth in the northern and ſouthern regions, every thing goes on quietly; and whatever ſtorms may happen in the atmoſphere, the ſolid earth cannot be affected. Innumerable circumſtances, however, may tend to hinder this diſcharge, and conſequently to accumulate the electric matter in particular places. One very obvious cauſe of this kind, is an exceſſive froſt taking place in any part of the earth whence the electric matter was wont to be diſcharged. This renders the air itſelf ſo electric, that it cannot receive the fluid; at the ſame time that the water on the ſurface of the earth, being hard frozen, becomes electric alſo, and incapable of conducting. Very dry ſeaſons likewiſe contribute to produce the ſame effect; and thus the accumulation of electricity in the warmer climates becomes prodigiouſly great.

It muſt here be obſerved, that, with regard to the operatious of nature, we cannot always reaſon analogically from our electric experiments. If a quantity of electricity is collected in any ſubſtance by artificial means, that quantity is taken off in a moment by the touch of any metallic ſubſtance, or other good conductor. As the whole earth, therefore, is filled with a conducting ſubſtance, namely water, it may very naturally be aſked, Why does not the ſuperfluous quantity of electric matter collected in one place, immediately diſperſe itſelf through all other parts of the earth by means of water with which it abounds? To obviate this difficulty, however, it needs only be remembered, that as the earth is quite full of electric matter all round, no quantity can enter any particular part, without being reſiſted by the reſt which is diffuſed through the whole globe. This reſiſtance will be proportioned to the facility with which it can eſcape at other places; and this it never can do, unleſs the earth is in a proper condition for emitting, and the atmoſphere for receiving, it. The preſſure, therefore, upon the accumulated quantity of electric matter ſoon becomes exceedingly great, and its diſpoſition to burſt out with violence is every day increaſed. At laſt, as the ſun ſtill continues to occaſion the deſcent of more and more of the electric fluid, that particular part of the earth becomes fully charged. The conſequence of this is, that the waters of fountains become foul; the electric matter being lodged in great quantity in the water, forces it into unuſual agitations, by which the earth is mixed with it. The ocean, for the ſame reaſon, is raiſed in huge billows, &c. and theſe appearances prognoſticate the ſhock, in the ſame manner that ſlight flaſhes from the knob of an electrified bottle prognoſticate a diſcharge of all the electricity contained in it.

Beſides the earthquakes above deſcribed, whoſe cauſe ſeems to depend entirely on a collection of electric matter in the bowels of the earth, there are others frequently felt in the neighbourhood of volcanoes, which are plainly owing to the efforts of the burning matter to diſcharge itſelf. Theſe, however, are but ſlight, and ſeldom extend to any conſiderable diſtance from the burning mountain. For a particular account of them, ſee the article VOLCANO.

EARTHQUAKES, *Artificial*. Chymiſtry furniſhes us with a method of making artificial earthquakes, which ſhall have all the great effects of natural ones; and, as it may illuſtrate the proceſs of nature in the production of theſe terrible phenomena underground, we ſhall add it here.

To twenty pounds of iron filings, add as many of ſulphur; mix, work, and temper the whole together with a little water, ſo as to form a maſs of the conſiſtence of a firm paſte. This being buried three or four feet under-ground, in ſix or ſeven hours time, will have a prodigious effect; the earth will begin to tremble, crack, and ſmoke, and fire and flame will burſt through. Such is the effect even of two cold bodies, in cold ground; and there wants only a ſufficient quantity of this mixture to produce a true Ætna. If it were ſuppoſed to burſt out under the ſea, it would produce a water ſpout; and if it were in the clouds, that effect would be thunder and lightning. However, water ſpouts and lightning are, without doubt, electrical phenomena.

EASE, in the ſea language, ſignifies as much as ſlacken, or let go ſlacker. Thus we ſay, *eaſe* the bowline, *eaſe* the ſheet; that is let them go ſlacker.

EASE *the Ship*, in ſea language, is the command given by the pilot to the ſteerſman, to put the helm cloſe to the lee ſide; or *hard-alee*, when the ſhip is expected to pitch or plunge her fore-part deep in the water while cloſe hauled.

EAST, in coſmography, one of the cardinal points of the horizon; being the point wherein the prime vertical interſects that quarter of the horizon in which the ſun riſes when in the equinoctial.

EASTER, a feſtival of the Chriſtian church, obſerved in memory of our Saviour's reſurrection.

The Greeks call it *paſga*, the Latins *paſcha*, an Hebrew word ſignifying *paſſage*, applied to the Jewiſh feaſt of the paſſover. It it is called *eaſter* in Engliſh, from the goddeſs Eoſtre, worſhipped by the Saxons with peculiar ceremonies in the month of April.

The Aſiatic churches kept their eaſter upon the very ſame day the Jews obſerved their paſſover; and others, on the firſt Sunday after the firſt full moon in the new year. This controverſy was determined in the council of Nice; when it was ordained, that eaſter ſhould be kept upon one and the ſame day, which ſhould always be a Sunday, in all Chriſtian churches in the world.

EATOOAS, in modern hiſtory, a name which the inhabitants of Otaheite give to an imaginary race of deities; two of whom, they ſay, at ſome remote period of time, inhabited the earth, and were the parents of the firſt man. The term is derived from *eothe*, which ſignifies *finiſhed*.

It had been aſſerted by Monſ. Bougainville, on the teſtimony of a native, whom he took with him to France, that human ſacrifices conſtitute a part of the religious ceremonies of the people of Otaheite which are offered to the Deities, called Eatooas: Captain Cook therefore on his voyage there, deſirous of having farther information concerning ſo intereſting a matter, went to a Morai, or place of worſhip, accompanied by Captain Furneaux of the adventure, having with them a ſeaman who ſpoke the language tolerably well, and ſeveral of the natives. Obſerving in the Morai a kind of bier with a ſhed erected over it, on which lay a corpſe and ſome proviſions, enquiry was made if the plantains were for the Eatooa or divinity, and if they ſacrificed to him hogs, dogs, fowls, &c. To all this a native replied in the affirmative. On enquiry being made whether they ſacrificed men to the Eatooa, the anſwer was *taato eno*, "bad men," firſt *typarrhy*, beating them till they were dead. When the queſtion was put, if good men were put to death in this manner, the reply was in the negative. Being aſked whether Towtows, that is, men of the loweſt claſs, were ever thus ſacrificed, if good men, a native replied in the negative, repeating the words *taato eno*, or bad men. It appeared, from what could be gathered upon this occaſion, that men, for certain crimes, were condemned to be ſacrificed to the Deity, provided they did not poſſeſs any property to purchaſe their redemption. But as more certain information, as well as a view of the ceremony, was obtained, by the laſt mentioned navigators on the voyage following, we are thereby enabled to preſent our readers with ſuch an account of the ceremony of human ſacrifices to the Eatooas, or inferior Deities, as we hope will prove ſatisfactory.

Captain Cook receiving information that a man was to be ſacrificed at the great morai, at Attahooroo, where the preſence of the king (Otoo) was neceſſary, requeſted the liberty to accompany him, and be preſent at the ſolemnity. This being readily granted, he ſet out, attended by ſome officers and others, and followed by Omai, a native of Otaheite, who was brought to England, and returned to his own country by Captain Cook.

As ſoon as they landed at Attahooroo, Otoo deſired that the ſailors might be ordered to continue in the boat; and that the perſons preſent would take off their hats as they ſhould come to the Morai. To this they immediately proceeded, followed by numbers of men and ſome boys; but not one woman was preſent. They found four prieſts with their aſſiſtants waiting for them, and on their arrival the ceremonies commenced. Here Otoo placed himſelf; the European viſitors and a few others ſtanding by him while the bulk of the people were removed to a greater diſtance.

The ceremonies now commenced. One of the aſſiſtants of the prieſts brought a young plantain tree, and laid it down before the king. Another approached, bearing a ſmall tuft of red feathers, twiſted on ſome fibres of the cocoa-nut huſk, with which he touched one of Otoo's feet, and afterwards retired with it to his companions. One of the prieſts who were ſeated at the Morai then began a long prayer, and at particular times ſent down young plantain trees, which were placed upon the ſacrifice. During this prayer, one of the natives who ſtood by the officiating prieſt, held in his hands two bundles, in one of which, as was afterwards found, was the royal maro: and the other, if it may be allowed the expreſſion, the ark of the Eatooa. Then one of the prieſts ſtanding at the feet of the corpſe, pronounced a long prayer, in which he was joined occaſionally by others, each of them holding a tuft of red feathers in his hand. While this prayer was repeating, ſome hair was pulled off the head of the intended ſacrifice, and the left eye was taken out; both which being wrapped in a green leaf, were preſented to the king, who, however, did not touch them, but gave to the man, who brought them to him, the tuft of red feathers which he had received from Towha, who was related to the king and chief of the diſtrict of Tettaha. This, with the eye and hair, were taken to the prieſts. Not long after this, the king ſent them another bunch of feathers.

In the courſe of this laſt ceremony, a king-fiſher making a noiſe, Otoo ſaid to Captain Cook, "That is the Eatooa;" and he ſeemed to conſider it as a favourable prognoſtic. The corpſe was then carried a little way, and laid under a tree, near which were fixed three thin pieces of wood neatly carved in various figures. He who ſeemed to be the chief prieſt, ſpoke for about a quarter of an hour, with different tones and geſtures; ſometimes appearing to expoſtulate with the deceaſed, at other times aſking ſeveral queſtions; then making various demands, as if the dead body had power himſelf, or intereſt with the Deity, to engage him to grant ſuch requeſts; among which, he deſired him particularly to deliver Eimeo, an adjacent iſland, with the inhabitants of which they were at war, Maheine its chief, the women, hogs, and other things of the iſland, into their hands; which was, indeed, the expreſs object of the ſacrifice. He then prayed near half an hour, in a whining tone, and two other prieſts joined in the prayer, in the courſe of which one of them plucked ſome more hair from the head of the corpſe, and put it upon one of the bundles. Then all the tufts of feathers were placed upon the bundles of cloth, which concluded the ceremony at this place.

The dead body was now carried to the moſt conſpicuous part of the Morai, with the feathers, and the two bundles of cloth, while the drums beat ſlowly. The feathers and bundles were laid againſt a pile of ſtones, and the body at the foot of them. The prieſts having again ſeated themſelves round the corpſe, renewed their prayers, while ſome of their aſſiſtants dug a hole about the depth of two feet, into which they threw the victim, and covered it over with ſtones and earth. While they were depoſiting the body in the grave, a boy ſqueaked aloud, upon which Omai told the captain, it was the Eatooa. In the mean time, a fire having been made, a lean dog half ſtarved was produced, and killed by twiſting the neck. The hair was then ſinged off, and the entrails being taken out, they were thrown into the fire, and left there to be conſumed; but the kidney, heart and liver, were baked on heated ſtones.

The carcaſe, after having been rubbed over with the blood of the animal, were with the liver, &c. laid down before the prieſts, who were ſeated round the grave praying. They, for ſome time, uttered ejaculations over the dog, while two men, at intervals, beat very loud on two drums; and a boy ſcreamed in a loud ſhrill voice three times. This, they ſaid, was to invite the Eatooa to feaſt on the banquet that they had prepared for him.

When the prieſts had finiſhed their prayers, the body, heart, liver, &c. of the dog, were placed on a whatta, or ſcaffold, about ſix feet in height, on which lay the remains of two other dogs, and of two pigs, that had been lately ſacrificed. The prieſts and their attendants now gave a ſhout, and this proclaimed the ceremonies ended for the preſent.

The unfortunate victim offered on this occaſion was, to appearance, a middle aged man, and one of the loweſt claſs of the people; but it did not appear that they had fixed upon him on account of his having committed any particular crime that deſerved death. It is certain, however, that they uſually ſelect ſuch guilty perſons for ſacrifices, or elſe vagabonds, who have no viſible way of procuring an honeſt livelihood. Having examined the body of the unhappy ſufferer, now offered up as the object of theſe people's adoration, our party obſerved, that it was bloody about the head, and much bruiſed upon the right temple, which denoted the manner in which he had been killed; and they were informed, that he had been knocked on the head with a ſtone.

The wretches who are devoted on theſe occaſions are never previouſly appriſed of their fate. Whenever any one of the principal chiefs conceives a human ſacrifice neceſſary, on any great emergency, he fixes upon the victim, and then diſpatches ſome of his truſty ſervants, who fall upon him ſuddenly, and either ſtone him to death or beat out his brains with a club. The king is then acquainted with it, whoſe preſence is ſaid to be abſolutely neceſſary at the ſolemn rites that follow; and, indeed, in the late performance, Otoo bore a capital part. The ſolemnity itſelf is called Poore Eree, or the prayer of the chief: and the victim is termed Taata-taboo, or conſecrated man. The Morai, where the late ſacrifice was offered, is always appropriated for the burial of the king of the whole iſland, and likewiſe of his family, and ſome other perſons of diſtinguſhed rank. It differs little, except in extent, from the common Morais. Its principal part is a large oblong pile of ſtones, about 13 feet in height, and contracted towards the top, with a quadrangular area on each ſide, looſely paved with pebbles, under which their gods are ſuppoſed to reſide occaſionally.

Not far from the end neareſt the ſea, is the place of ſacrifice, where is a very large whatta, or ſcaffold, on which the offerings of fruits, and other vegetables are placed; but the animals are laid on a ſmaller one, and the human ſacrifices are interred under the pavement. There are ſeveral reliques ſcattered about this place; ſuch as ſmall ſtones raiſed in ſeveral parts of the pavement; ſome with bits of cloth faſtened round them; others intirely covered with it; and upon the ſide of the large pile fronting the area are a great number of pieces of carved wood, in which their gods are ſuppoſed to reſide occaſionally.

There is an heap of ſtones at one end of the large ſcaffold, with a ſort of platform on one ſide. On this are depoſited all the ſkulls of the human ſacrifices, which are taken up after they have remained under ground for ſome months. Juſt above them many of the carved pieces of wood are placed; and here the Maro, and the other bundle, ſuppoſed to contain the god Ooro, were laid during the celebration of the late ſolemn rites.

It is probable, that this barbarous cuſtom of offering human ſacrifices prevails in all, or moſt of the iſlands of the Pacific Ocean, however diſtant from each other ſome of them may be. And though it may be ſuppoſed that not more than one perſon is offered at one time, either at Otahetite, or other iſlands, yet theſe occaſions, in all probabilty occur ſo frequently, as to make a terrible havock of the human ſpecies; for no leſs than 49 ſkulls of former victims were counted lying before the Morai at Attahooroo; and as none of thoſe ſkulls appeared to have ſuffered any conſiderable change or decay from the weather, it may be inferred that a ſhort time had elapſed ſince the victims to whom they belonged had been offered.

This horrid practice, though no conſideration whatever can make it ceaſe to be deteſtable, might, perhaps, be thought to be leſs detrimental, in ſome reſpects, if it contributed to impreſs any awe for the deity, or veneration for religion, upon the minds of the ſpectators; but this was far from being the caſe on the late occaſion; for though a vaſt multitude had aſſembled at the Morai, they ſhewed very little reverence for what was tranſacting: and Omai happening to arrive after the ceremonies had begun, many of the iſlanders thronged round him, and were engaged, for the remaining part of the time, in making him recount ſome of his adventures; to which they liſtened with great eagerneſs of attention, regardleſs of the ſolemn offices which their prieſts were then performing. Indeed, the prieſts themſelves, except the one who ſuſtained the principal part, either from their being familiarized to ſuch objects, or from their repoſing no great degree of confidence in the efficacy of their religious inſtitutions, maintained very little of that ſolemnity, ſo neceſſary to give to acts of devotion their proper effect.

Their habit was but an ordinary one; they converſed together with great familiarity; and the only attempt they made to preſerve decorum, was by exerting their authority, to prevent the populace from encroaching on the ſpot, and to ſuffer our party, as ſtrangers, to come forward. They were, however, very candid in the anſwers which they gave to any interrogatories that were put to them, with regard to this inhuman inſtitution. Being aſked, what was the deſign of it? They replied, that it was an antient cuſtom, and highly pleaſing to their god, who came and fed upon the ſacrifices; in conſequence of which, he granted their petitions. It was then objected, that he certainly did not feed on theſe, as he was neither ſeen to do it, nor were the bodies of the ſacrificed animals ſoon conſumed; and that as to the corpſe of a human victim, they prevented his feeding on that by interring it. In anſwer to theſe objections, they obſerved, that he came in the night, inviſibly, and fed only on the ſoul, or immaterial part, which (as theſe people ſay) remains about the place of ſacrifice, till the carcaſe of the victim is wholly waſted by putrefaction.

Human ſacrifices are not the only ſtrange cuſtoms that ſtill prevail among the inhabitants of Otaheite, though, in many reſpects, they have emerged from the brutal manners of ſavage life. Beſides cutting out the jaw bones of their enemies ſlain in battle, which they carry about with them as trophies, they, in ſome meaſure, offer up their bodies to the Eatooa: for after an engagement, in which they have come off victorious, they collect all the dead, and bring them to the Morai, where, with great form and ceremony, they dig a large hole and bury them all in it, as ſo many offerings to their divinities.

The ſame religious ceremonies, and the ſame horrid practices of human ſacrifices to the deities, called Eatooha, prevail through the whole of Sandwich iſlands, where they hold the Morais or

Burial places, in which theſe deities are ſuppoſed to reſide, in the moſt profound veneration. Although the voyagers, who laſt viſited theſe iſlands, had ſuch repeated proofs of the ſacred regard the natives had for theſe Morais; yet ſuch was the wantonneſs of the common crew, that, unknown to their officers, they removed their gods, and diſturbed the aſhes of the dead. The compiler of the narrative of the voyage, deſirous of concealing a circumſtance ſo reproachful to this country, cautiouſly omitted it; and to obviate enquiry into the reaſon of the very different reception with which our people met on their ſpeedy return, to repair ſome damages which the ſhip had received; affected the utmoſt ſurpriſe at the hoſtilities offered them, unwilling to ſtate the real cauſe.

To this event may be imputed the fatal loſs of that ſkilful, intrepid, and enterpriſing navigator Captain Cook, who was ſo much eſteemed by his country; and revered by all nations.

For the particulars of the death and tranſactions of that immortal man, during his three voyages round the world, together with thoſe of all the navigators from his time, down to the laſt account of the New Settlement at Port Jackſon in Botany Bay, we refer our readers to the TEN *firſt numbers of Bankes's Geography*, which may be purchaſed ſeparate from the work.

EAU *de Luce*, is a kind of volatile liquid ſoap, of a ſtrong, penetrating ſmell. The following inſtructions will ſerve for making it: take four ounces of rectified ſpirit of wine, and in it diſſolve ten or twelve grains of white ſoap; filtrate this ſolution; then diſſolve in it a dram of rectified oil of amber, and filtrate again: mix as much of this ſolution with the ſtrongeſt volatile ſpirit of ſal ammoniac, in a cryſtal glaſs bottle, as when ſufficiently ſhook, ſhall produce a beautiful milky liquor. If upon its ſurface be formed a cream, ſome more of the oily ſpirit of wine ought to be added.

EBBING *and* **Flowing** *of the Sea*. See Tides.

EBENUS, the ebony tree, a genus of the decandria order, belonging to the diadelphia claſs of plants. There is but one ſpecies, a native of Crete and ſome other iſlands of the Archipelago.

Ebony wood, is brought from the Indies, exceedingly hard and heavy, ſuſceptible of a very fine poliſh, and on that account uſed in Moſaic and inlaid works, toys, &c. There are divers kinds of ebony: the moſt uſual among us are black, red, and green, all of them the product of the iſland of Madagaſcar, where the natives call them, indifferently, *hazon mainthi*, q. d. *black wood*. The iſland of St. Maurice, belonging to the Dutch, likewiſe furniſhes part of the ebonies uſed in Europe.

The cabinet-makers, inlayers, &c. make pear-tree, and other woods, paſs for ebony, by giving them the black colour thereof. This ſome do by a few waſhes of a hot decoction of galls; and when dry, adding writing ink thereon, and poliſhing it with a ſtiff bruſh, and a little hot wax; and others heat or burn their wood black. See the article, Dyeing or Staining Wood in the Treatiſe on Dyeing.

EBULLITION, in phyſics, the act of emitting bubbles, by a vehement agitation of the parts of a fluid, produced by fire, or otherwiſe. Philoſophers are diſagreed about the cauſe and manner of ebullition. See Boiling.

Ebullition, in chymiſtry, is uſed for a violent inteſtine motion, or colluctation of parts, occaſioned by the mixtures of ſalts of different natures.

ECARTELE, in heraldry, a French term for quartering.

ECCE-HOMO, among painters, a name given to a picture, wherein our Saviour is repreſented in a purple robe, with a crown on his head, and a reed in his hand, ſuch as he was preſented before Pilate by the Jews. The phraſe is Latin, borrowed from the words of the Jews themſelves: q. d. this is the man.

ECCHYMOSIS, Εϰχυμωσις, the effuſion of blood from a rupture in ſome of the ſmall veins near the ſkin, cauſing a lividity or blueneſs thereof. This is alſo called *echymoma*, εϰχυμωμα, and ſtands diſtinguiſhed from *enchymoſis*, where there is no extravaſation.

ECCLESIASTES, a canonical book of the Old Teſtament, the deſign of which is to ſhew the vanity of all ſublunary things.

It was compoſed by Solomon; who enumerates the ſeveral objects on which men place their happineſs, and then ſhews the inſufficiency of all worldly enjoyments.

The Talmudiſts make king Hezekiah to be the author of it; Grotius aſcribes it to Zorobabel, and others to Iſaiah; but the generality of commentators believe this book to be the produce of Solomon's repentance, after having experienced all the follies and pleaſures of life.

ECCLESIASTIC, or **Eccleſiastical**, ſomething belonging to, or ſet apart for the church, in contradiſtinction to *civil* or *ſecular*, which regard the world. There are *eccleſiaſtical* things and perſons; *eccleſiaſtical law, juriſdiction, hiſtory, ceremonies, diſcipline, preferments*, &c. *Eccleſiaſtical* perſons are either regular or ſecular. See Regular and Secular. In the empire there are three *eccleſiaſtical* electors, viz. the archbiſhops of Mentz, Treves, and Cologne. In France, they have *eccleſiaſtical peers*, &c.

Eccleſiaſtic *Courts*. See Court.

ECCLESIASTICAL *State*, in geography, the pope's dominions in Italy. Theſe dominions are differently divided by geographers. The pope may be conſidered in two reſpects, as the ſpiritual head and monarch of the Roman church, and as a conſiderable temporal prince in Italy. In the firſt character, his ſubjects may be divided into two claſſes, viz. clergy and laity; the former may not unfitly be compared to a ſpiritual ſtanding army, whoſe buſineſs is to maintain his rights and conqueſts; and the reſt, the laity, as his tributary ſubjects, who are obliged to maintain thoſe forces at their own charge; and if one may judge of the greatneſs of their number, by what pope Paul IV. uſed to boaſt, that he had 228,000 pariſhes under his juriſdiction (all of whom have at leaſt one or more prieſts,) and 4400 monaſteries, it will appear no inconſiderable army. But their number has been much leſſened ſince the Reformation.

Indeed the power of the pope has been gradually declining for ſome time, and more eſpecially ſo within theſe few years, as appears from his reception by the preſent emperor of Germany.

ECCLESIASTICUS, an apocryphal book, generally bound up with the ſcriptures, ſo called, from its being read in the church, *eccleſia*, as a book of piety and inſtruction, but not of infallible authority. The author of this book was a Jew, called *Jeſus the ſon of Sirach*. The Greeks call it the *Wiſdom of the ſon of Sirach*.

ECCOPE, Εϰϰοπη, in ſurgery, the ſame with exciſion or amputation. The word is formed from the Greek, εϰϰοπλειν, *exſcindere, to cut off*. Eccope is likewiſe uſed for a kind of fracture, or ſolution of continuity, of the ſkull, by a ſimple inciſion.

ECCOPROTICS, Εϰϰοπρωτιϰα, in medicine. See Cathartics.

ECHINITES, or Echinitæ, in natural hiſtory, a name given to the foſſil ſhells of the ſeveral ſpecies of *echini marini*, and to the ſtones formed in them. See Centronia.

ECHINUS, in vermeology, a genus of inſects belonging to the order of vermes molluſca. The body is roundiſh, covered with a bony cruſt, and often beſet with moveable prickles; and the mouth is below, and conſiſts of five valves. The eſculentus, or eatable echinus, is of a hemiſpherical form, covered with ſharp ſtrong ſpines, above half an inch long; commonly of a violet colour; moveable; adherent to ſmall tubercles elegantly diſpoſed in rows. Theſe are their inſtruments of motion by which they change their place. This ſpecies is taken in dredging, and often lodges in cavities of rocks juſt within low water mark. They are eaten by the poor in many parts of England, and by the better ſort abroad. In old times they were a favourite diſh. They were dreſſed with vinegar, honied wine or mead, parſley or mint; and thought to agree with the ſtomach. They were the firſt diſh in the famous ſupper of Lentulus, when he was made *flamen Martialis*, or prieſt of mars. By ſome of the concomitant diſhes, they ſeem deſigned as a whet for the ſecond courſe, to the holy perſonages, prieſts and veſtals, invited on that occaſion. Many ſpecies of ſhell fiſh made part of that entertainment. The lacunoſus, or oval echinus, is of on oval depreſſed form; on the top it is of a purple colour, marked with a quadrefoil, and the ſpaces between tuberculated in waved rows; the lower ſide, ſtudded, and divided by two ſmooth ſpaces. Length, four inches. When clothed, it is covered with ſhort thickſet briſtles mixed with very long ones. There are 15 other ſpecies, all natives of the ſea. For the claſſification, ſee Syſtem of Vermeology.

ECHIUM, viper's bugloſs; a genus of the monogynia order, belonging to the pentandria claſs of plants. There are ſeven ſpecies, three of which are natives of Britain. None of them have any remarkable property except that the flowers of one ſpecies (the vulgare) are very grateful to bees.

ECHO, or Eccho, a ſound reflexed, or reverberated from a ſolid, concave body, and ſo repeated to the ear. The word is formed of the Greek ηχος, *ſound*, of the verb ηχεω, *ſono, I ſound*. See Syſtem of Acouſtics, Definition III.

Echo is alſo uſed for the place where the repetition of the ſound is produced, or heard. This is either natural or artificial. In echoes, the place where the ſpeaker ſtands, is called the *centrum phonicum*; and the object, or place, that returns the voice, the *centrum phonocampticum*.

Echo, in architecture, is applied to certain vaults, and arches, moſt commonly of elliptical, or parabolical figures; uſed to redouble ſounds, and produce artificial echoes.

Echo, in muſic, pieces compoſed in imitation of echoes. Organs and harpſichords have what they call an echo ſtop.

Echo, in poetry, a kind of compoſition wherein the laſt words or ſyllables of each verſe contain ſome meaning, which, being repeated apart, anſwers to ſome queſtion or other matter contained in the verſe; as in this beautiful one from Virgil.

Crudelis mater magis, an puer improbus ille?
Improbus ille puer, crudelis tu quoque mater.

The elegance of an echo conſiſts in giving a new ſenſe to the laſt words; which reverberate, as it were, the motions of the mind, and by that means affect it with ſurpriſe and admiration.

ECHOMETER, in muſic, a kind of ſcale, or rule, with ſeveral lines divided thereon, ſerving to meaſure the duration, or length, of ſounds, and to find their intervals and ratios. The word is formed of the Greek ηχος, *ſound*, and μετρον, *meaſure*.

ECHOS, Ηχος, a ſound, in phyſic. In Hippocrates, this frequently imports what the Latins call *tinnitus aurium*, and the Engliſh a ringing of the ears; a ſymptom very frequent in acute diſtempers.

ECLECTICS, ancient philoſophers, who, without attaching themſelves to any particular ſect, ſelected whatever appeared to them the be ſtand moſt rational, from each. Hence their denomination: which, in the original Greek, ſignifies, *that may be choſen*, or, *that chooſes*; of the verb εκλεγω, *I chooſe*.

ECLIPSE, from εκλειψις, of εκλειπω, *deficio*, *I fail*, in aſtronomy, a privation of the light of one of the luminaries, by the interpoſition of ſome opaque body, either between it and the eye, or between it and the ſun. See Syſtem of ASTRONOMY, Sect. XIV.

ECLIPTIC, in aſtronomy, a great circle of the ſphere, ſuppoſed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about 23° 30′, which is the ſun's greateſt declination; or, more ſtrictly ſpeaking, it is that path or way among the fixed ſtars, that the earth appears to deſcribe to an eye placed in the ſun.

Some call it *via Solis*, "the way of the ſun;" becauſe the ſun in his apparent annual motion never deviates from it, as all the other planets do more or leſs. It is called *ecliptic*, by reaſon all eclipſes happen when the planets are in, or near its node. See Syſtem of ASTRONOMY, Sect. IX.

ECLIPTIC, in geography, a great circle on the terreſtrial globe, not only anſwering to, but falling within, the plane of the celeſtial ecliptic. See Syſtem of GEOGRAPHY.

ECLOGUE, in poetry, a kind of paſtoral compoſition, wherein ſhepherds are introduced converſing together. The word is formed from the Greek εκλογη, *choice*; ſo that, according to the etymology, *eclogue* ſhould be no more than a ſelect or choice piece; but cuſtom has determined it to a farther ſignification, viz. a little elegant compoſition in a ſimple, natural ſtyle and manner. Idyllion and eclogue, in their primary intention, are the ſame thing: thus, the idyllia, ειδυλλια of Theocritus, are pieces wrote perfectly in the ſame vein with the *eclogæ* of Virgil. But cuſtom has made a difference between them, and appropriated the name *eclogue*, to pieces wherein ſhepherds are introduced ſpeaking; idyllion, to thoſe wrote like the *eclogue*, in a ſimple natural ſtyle, but without any ſhepherds in them.

ECTHLIPSIS, in the Latin proſody, a figure whereby an *m* is retrenched, or cut off, chiefly at the end of a word, when the following word begins with a vowel, or an *h*. The word is Greek, εκθλιψις, which ſignifies *eliſion*. Thus, in *multum ille*, *&* *terris jactatus & alto*. Virg. In ſcanning the verſe, we drop the *m* at the end of *multum*, and only make three ſyllables in the two firſt words, *mult-il-le*.

ECTHYMA, from εκθυω, *I break out*, a name given by Hippocrates to any puſtule, or cutaneous eruption.

ECTHYMOSIS, of εκ, *ex*, and θυμος, *animus*, *mind*, in medicine, a vehement agitation and dilatation of the blood and ſpirits; ſuch as happens in extraordinary emotions of joy.

ECTOMIAS, from εκτεμνω, *I cut off*, a name uſed by the ancient phyſicians, to expreſs a caſtrated animal.

ECU, or ESCU, the French crown. See CROWN.

ECUSSON, in heraldry, an ineſcutcheon, or little eſcutcheon. See ESCUTCHEON.

EDDA, in antiquities, is a ſyſtem of the ancient Icelandic, or Runic mythology, containing many curious particulars of theology, philoſophy, and manners, of the northern nations of Europe; or of the Scandinavians, who had migrated from Aſia, and from whom our Saxon anceſtors were deſcended. Mr. Mallet apprehends that it was originally compiled, ſoon after the Pagan religion was aboliſhed, as a courſe of poetical lectures, for the uſe of ſuch young Icelanders as devoted themſelves to the profeſſion of a ſcald or poet. It conſiſts of two principal parts; the firſt containing a brief ſyſtem of mythology, properly called the Edda; and the ſecond being a kind of art of poetry, and called Scalda or Poetics.

EDDISH, or EADISH, the latter paſture, or graſs, which comes after mowing or reaping; otherwiſe called *eargraſs*, *earſh*, and *etch*.

EDDY, Sax. of *ed*, *backward*, and *ea*, *water*, in ſea language, is when the water, at any place, runs back, contrary to the tide, or ſtream, and ſo falls into the current again. The ſeamen call that *eddy water* which falls back, as it were, on the rudder of a ſhip under ſail, the *dead water*. An *eddy wind* is that which returns, or is beat back, from any ſail, &c.

EDGE *in with a Ship*, in the ſea language, is ſaid of a chace, that is making up to it.

EDGE *away*, is to decline gradually from the ſhore, or from the line of the courſe which the ſhip formerly ſteered, when ſhe ſails nearer the direction of the wind, or larger before the wind.

EDGINGS, in gardening, rows of ſhrubs, herbs, or flowers, placed by way of borders around beds, compartiments, &c. For the edgings of compartiments, box ſeems the moſt proper. See Treatiſe on GARDENING.

EDICT, an inſtrument, ſigned and ſealed by a prince, to ſerve as a law to his ſubjects. Edicts have no room in England, where the enacting of laws is not lodged in the king, but in the parliament. In the Roman law we find frequent mention of the *edict of the prætor*, *quod prætor edixit*, which was a phraſe appropriated to the ordinances of the prætor; though it was ſometimes alſo uſed on other occaſions. In the French law, *edicts*, *edits*, make a great figure; they are of various kinds; ſome importing a new law, or regulation, as the edict of duels, that of ſecond marriages, &c. Others the erection of new offices, eſtabliſhment of duties, rents, &c. Sometimes articles of pacification, as the edict of Nantz, paſſed by Henry IV. in 1598, and revoked by Louis XIV. in 1685, &c. Edicts are all ſealed with green wax, to ſhew that they are perpetual and irrevocable. Edicts with them are much the ſame as proclamations with us; but with this difference, that the former have the authority of a law, in themſelves, from the power which iſſues forth; whereas the latter are only declarations of a law, to which they refer, and have no power in themſelves.

EDIFICE, ÆDIFICIUM, a building. The word is formed of the Latin, *ædes* and *facio*, *I make*. See Syſtem of ARCHITECTURE, on the principles of the art.

EDILE, or rather ÆDILE. See ÆDILE.

EDITOR, of *edo*, *I publiſh*, in the commonwealth of learning, a perſon who takes care of publiſhing the work of another author. Eraſmus was a great editor of ancient writings; the Louvain doctors, Scaliger, Petavius, Fa. Sirmond, biſhop Walton, Mr. Hearn, &c. are learned editors; the Benedictines of the fathers; the Dauphins, of the claſſics; Hardouin, of the councils, &c.

EDUCATION, the art of bringing up, forming, and inſtructing children. The follies of a too delicate education are well expreſſed in that device of an ape; which, by over careſſing and hugging its young ones, ſtrangles them; with this motto, *complectando necat*. Octavius Ferrarius has a very good Latin treatiſe on the ſubject of education, intitled *Chiron*; the name of the centaur who was Achilles's tutor.

Mr. Lock's excellent treatiſe of education is known to every body. Quintillian employs the ſecond chapter of his firſt book in enquiring whether a domeſtic, or a college, education, be preferable, i. e. whether it be better to bring up one's children at home, or ſend them to the colleges and public ſchools. After urging all that can be ſaid on either ſide, he concludes for a college or ſchool education.

The plan of education, whether it be domeſtic or collegiate, ſhould be ſuited to the ſtation and views of parents, and to the genius of their children; and it is alſo right to conſult their conſtitution and inclination. It is of great importance, that thoſe who are deſtined to occupy ſuperior ſtations in ſociety, ſhould enjoy the benefits of an enlarged and liberal education; that they ſhould be furniſhed with every ſubſtantial and ornamental accompliſhment; and thoſe that are intended for any particular profeſſion or employment ſhould be principally directed to thoſe ſtudies which are appropriated to their reſpective views; and in every rank of life, an attention to the morals of youth ſhould be a primary object. Though the municipal laws of moſt countries have made no proviſion for conſtraining a parent to beſtow a proper education on his children; yet in the caſe of religion they are under peculiar reſtrictions in our own country. Some of theſe reſtrictions, as they affect proteſtants who diſſent from the religion of the ſtate, may be thought both impolitic and injurious, and have, therefore, lately been conſiderably relaxed; but thoſe who are deſigned to prevent the progreſs of popery are prudent and neceſſary. Thus, if any perſon ſends a child under his care beyond the ſeas, to be inſtructed in any popiſh college, &c. in the principles of the popiſh religion, or ſhall contribute towards his maintenance, he ſhall forfeit one hundred pounds, beſides the diſabilities incurred by the child ſo ſent. 1 Jac. I. cap. 4. and 3 Jac. I. cap. 5. 11 and 12 W. III. cap. 4. and both ſhall be incapable of ſuing in law or equity, of being executor or adminiſtrator, of enjoying any legacy or deed of gift, or of bearing any office in the realm; and he ſhall forfeit all his goods and chattels, and likewiſe all his real eſtate for life. 3 Car. I. cap. II.

EDULCORATION, of *edulco*, *I ſweeten*, in pharmacy, is the dulcifying or ſweetening of any food, or remedy, by means of honey, ſugar, or ſyrups.

EDULCORATION, in chymiſtry, denotes the freſhening or purging of any thing of its ſalts, by repeated lotions, or waſhings in cold water. Such is the dulcifying of the precipitates of mercury, metals, &c. by waſhing away thoſe ſharp ſalts, by whoſe means they had been diſſolved, or which had been mingled with them, to effect a diſſolution.

EDULCORATION, in metallurgy, is the ſeparating, by a ſolution of water, of the ſalts that have been left adhering to a body after any operation. This is properly a kind of moiſt ſolution, the ſaline parts adhering to bodies, not ſoluble in water, being by that menſtruum taken up and eaten off from the body, and the ſolution afterwards ſeparated from the remaining ſolid, either by ſubſidence or filtration.

EDYSTONE *Light-houſe*, lying off Plymouth harbour, was firſt erected by the corporation of the Trinity houſe, in 1696; in conſideration of which, the maſters, &c. of Engliſh ſhipping agreed to pay one penny a ton outwards and inwards. It was demoliſhed by the ſtorm of 1703, and re-erected by act of parliament in the 4th of queen Anne, and the ſame duty on tonnage of ſhips granted for its ſupport, which law was enforced in the 8th of Anne. It has been ſince deſtroyed and rebuilt.

EEL, *Anguilla*, in ichthyology, a ſpecies of the muræna. See MURÆNA.

EELS, *Microſcopic*, in ſour paſte. The long-bodied animalcules, diſcovered by the microſcope in vinegar, ſour paſte, and many other ſubjects, have, from their figure, been generally diſtinguiſhed from the reſt of the microſcopic animalcules, by the name of eels. See ANIMALCULES, and MICROSCOPICAL OBJECTS.

EELS *in Vinegar*, are ſimilar to thoſe in ſour paſte. The taſte of vinegar was formerly thought to be occaſioned by the biting of theſe little animals, but that opinion has been long ago exploded. Mentzelius ſays, he has obſerved the actual transformation of theſe little creatures into flies: but as this hath never been obſerved by any other perſon, nor is there an inſtance of ſuch a transformation in any other animalcule, it ſeems probable that Mentzelius hath been miſtaken in his obſervations.

EEL *Spear*, a forked inſtrument with three or four jagged teeth, uſed for catching eels; that with four teeth is the beſt. This is ſtruck into the mud at the bottom of the river; where, if it ſtrikes againſt eels, it is ſure to bring them up.

EFFEARE', in heraldry, a French term for a beaſt reared on its hind legs as if frighted, and reſembling ſalient.

EFFECT, the reſult or conſequence of the application of a cauſe, or agent, on ſome ſubject. It is one of the great axioms of philoſophy, that full or adequate effects are always proportionable to the powers of their cauſes.

EFFECT is alſo of ſome farther import in the arts; as when we ſay in painting and architecture, that ſuch a contraſt, or ſuch a drapery, or ſuch an attitude, have a fine or an ill effect, i. e. are beautiful, noble, or the contrary. Too many breaks, and little enrichments, in a building, have a poor effect, i. e. they give it a mean aſpect. See Treatiſe on PAINTING, and Syſtem of ARCHITECTURE, on the principles of the Art.

EFFECTS, in commerce, &c. the goods poſſeſſed by any perſon, whether moveables or immoveable; particularly thoſe which merchants and dealers acquire by trade. See CHATTELS.

EFFECTIVE *Men*, in military language, are ſoldiers fit for ſervice.

EFFEMINATE, void of the qualities which diſtinguiſh and adorn the male ſex; acting or behaving like a woman: voluptuous or luxurious.

EFFEMINATE, *effeminati*, according to the Vulgate, are mentioned in ſeveral places of Scripture. The word is there uſed to ſignify ſuch as were conſecrated to ſome profane god, and proſtituted themſelves in honour of him.

The Hebrew word, *kadeſh*, tranſlated *effeminatus*, properly ſignifies *conſecrated*, and hence was attributed to thoſe of either ſex, who publicly proſtituted themſelves in honour of Baal and Aſtarte. Moſes expreſly forbids theſe irregularities among the Iſraelites; but the hiſtory of the Jews ſhews that they were notwithſtanding frequently practiſed. Levit. xxiii. 18. Calmet. Dict. Bibl. in voc.

EFFENDI, in the Turkiſh language, ſignifies maſter: and accordingly it is a title very extenſively applied; as to the mufti and emirs: to the prieſts of moſques, to men of learning, and of the law. The grand chancellor of the empire is called *reieffendi*.

EFFERVESCENCE, is commonly uſed for a light ebullition, or a briſk inteſtine motion produced in a liquor by the firſt action of heat, without any notable ſeparation of its parts.

EFFERVESCENCE, in chymiſtry, is not applied to all ebullitions or motions produced by fire, but only to thoſe reſulting from the mixture of bodies of different natures, which, by their acting on one another, occaſion a heat, reſembling the ebullition or boiling produced by fire.

EFFERVESCENCE, in vintage, a term appropriated by Portzius and others, to ſignify that working of wine, which is by ſome, though improperly, called fermentation.

EFFICACIOUS, EFFECTUAL, in theology. Within theſe 150 years there have been great diſputes on the ſubject of *efficacious* grace. Grace is uſually divided into ſufficient and *efficacious*; though the Janſeniſts hold, that there is no grace ſufficient but what is *efficacious*, i. e. but what effectually determines the will to act. *Efficacious* grace is that which enlightens the mind, and touches the heart, in ſuch a manner, as always to produce its effect, however it be oppoſed or reſiſted by the will.

EFFICIENT, in philoſophy. An EFFICIENT *cauſe* is that which produces an effect. See CAUSE and EFFECT. Philoſophers uſually diſtinguiſh four kinds of cauſes in nature; the *efficient*, *final*, *formal*, and *material*.

EFFIGY, EFFIGIES, a portrait, or repreſentation of a perſon to the life.

EFFIGY is alſo uſed for the print or impreſſion of a coin, repreſenting the prince's head who ſtruck it.

EFFIGY, *to execute or degrade in*, denotes the execution or degradation of a condemned, contumacious criminal, who cannot be apprehended or ſeized. In France they hang a picture on a gallows, or gibbet, wherein is repreſented the criminal, with the quality or manner of the puniſhment: at the bottom is written the ſentence of condemnation. Such perſons as are ſentenced to death are executed in *effigy*.

EFFLORESCENCE, of *ex*, *out*, and *flos*, *flower*, in botany, denotes the blooming of a flower.

EFFLORESCENCE, in chymiſtry, denotes an operation which certain bodies undergo, when a kind of metal or powder is formed on their ſurfaces; and this may happen either by decompoſition or drying; as to cobalt in the firſt caſe, and to the cryſtals of marine alkali, Glauber's ſalt, alum, &c. in the ſecond.

EFEFORESCENCF, in medicine, a breaking out of humours in the ſkin; as in the meaſles, or the like. See EXANTHEMA.

EFFLORESCENTIA, in botany, (from *effloreſco*, to bloom); the preciſe time of the year and month in which every plant ſhews its firſt flowers. Some plants flower twice a year, as is common between the tropics; others oftener, as the monthly roſe. The former are called by botaniſts *biferæ*; the latter, *multiferæ*. Linnæus and Adanſon have given a ſketch of the different times in which plants flower at Upſal and Paris.

EFFLUVIUM, in phyſiology, a term much uſed by philoſophers and phyſicians, to expreſs the minute particles which exhale from moſt, if not all, terreſtrial bodies, in form of inſenſible vapours. See PERSPIRATION.

EFFLUVIA, in medicine, are aſſigned as the cauſe of various diſorders, eſpecially of the contagious kind. Thus, when a conſiderable quantity of putrid *effluvia* has been admitted into the blood, beſides acting thereupon ſlowly, by way of inquinamentum, or ferment, they ſeem immediately to affect the nerves, and thereby to bring on ſome extraordinary diſorder of the whole frame. Hence ariſe ſpaſms, obſtructions, palpitation, a high degree of fever, or a languid circulation, chilneſs, or intenſe heat, and a variety of contrary ſymptoms, according to the different affection of the nerves. To putrid *effluvia* is likewiſe owing the jaii diſtemper, which is the ſame with the hoſpital fever.

Effluvia iſſuing from corrupted ſubſtances chiefly conſiſt of the phlogiſton or ſulphur principle, ſince they ſo readily unite with, and volatilize acids, as appears from the increaſe and particular change of the ſmell. But it is proper to remark, that from a ſimple putrid ſubſtance the phlogiſton does not ariſe alone, but combined with the ſaline parts of the body: for this principle, when ſingle, is perhaps imperceptible to the ſmell; and, when diveſted of theſe ſalts, is never, ſo far as is known, peſtilential; ſo that the deleterious particles of rotten ſubſtances ſeem to conſiſt of a certain combination of the ſuphureous with the ſaline principle, which united, not only become the moſt irritating ſtimuli to the nerves, but act upon the humours as a putrid ferment in promoting their corruption. Pringle's Obſ. on Diſeaſes of the Army, p. 186, 385, &c. Dr. White, availing himſelf of the diſcoveries of Dr. Prieſtley, has applied *nitrous air*, in the manner propoſed by him, for aſcertaining the ſalubrity of different ſpecimens of air, and the effects of various kinds of *effluvia* upon it.

The earth ſends forth effluvia and ſteams in great abundance, and many things attributed to other agents, are really performed by them. Dr. Woodward has very juſtly attributed great effects to them on foſſils of many kinds; and it is poſſible many more of the preſent appearances of ſubterranean bodies may be owing to them than are at preſent imagined. The figures and delineations on ſtones, in form of trees and ſhrubs, have often their origin from theſe effluvia, getting into the cracks of them; and it is poſſible, that the ſtalactitæ, which we find on the roofs of caverns, may be in great part alſo formed by their means. Phil. Tranſ. N° 169. p. 920.

EFFLUXION, a flowing out, from *ex*, *out of*, and *fluere*, *to flow*.

EFFUSION, the pouring out of any liquid thing with ſome degree of force. In the ancient heathen ſacrifices there were divers effuſions of wine, and other liquors, called libations.

EFFUSION, or FUSION, in aſtronomy, denotes that part of the ſign Aquarius, repreſented on celeſtial globes and planiſpheres, by the water iſſuing out of the urn of the water bearer. See AQUARIUS.

EFFUSION *of Blood*, *effuſio ſanguinis*, in our old writers, is uſed for the mulct, fine, or penalty, impoſed for the ſhedding of blood. This the king uſed frequently to grant to lords of manors. Among others it was granted to the abbot of Glaſtonbury.

EFT, in amphibiology, the Engliſh name of the common lizard, a ſpecies of the genus lacerta. See LACERTA.

EGG, in natural hiſtory, a part formed in the females of certain animals; which under a ſhell or cortex, includes an embryo, or fœtus of the ſame ſpecies; the parts whereof are afterwards diſplayed and dilated; either by incubation, or by the acceſſion of a nutritious juice. The ſpecies of animals that lay eggs are particularly denominated *oviparous*; and the part wherein the egg is formed, the *ovary*. Of the various kinds of eggs thoſe of hens or pullets being the moſt uſual, and which have been the moſt obſerved, we ſhall ſay ſomething of the ſtructure thereof, and the generation of the chick therein.

The chick in the egg is firſt nouriſhed by the albumen; and when this is conſumed, by the vitellus, as with milk. If we compare the chalazæ to the extremities of an axis paſſing through the vitellus, which is of a ſpherical form, this ſphere will be compoſed of two unequal portions, its axis not paſſing through its centre; conſequently, ſince it is heavier than the white, its ſmaller portion muſt always be uppermoſt in all poſitions of the egg.

The yellowiſh white round ſpot, called *cicatricula*, is placed on the middle of the ſmaller portion of the yolk; and therefore, from what has been ſaid in the laſt paragraph, muſt always appear on the ſuperior part of the vitellus.

Not long before the excluſion of the chick, the whole yolk is taken into its abdomen; and the ſhell, at the obtuſe end of the egg, frequently appears cracked ſome time before the excluſion of the chick. The chick is ſometimes obſerved to perforate the ſhell with its beak. After excluſion, the yolk is gradually waſted, being conveyed into the ſmall guts by a ſmall duct.

Eggs, *Preſervation of.* Mr. de Reaumur, of the Paris academy, thinking nothing that could be a public benefit beneath the cognizance of a philoſopher, beſtowed conſiderable pains on finding a method of preſerving eggs for a long time, and ſucceeded at length ſo far in it, as to be able to produce eggs of months, nay years old, which taſted as freſh and well as if they had been laid but the day before. The egg always is quite full, when it is firſt laid by the hen, but from that time it gradually becomes leſs and leſs to its decay; and however compact and cloſe its ſhell may appear, it is nevertheleſs perforated with a multitude of ſmall holes, though too minute for the diſcernment of our eyes. The effect of theſe, however, is evident, by the daily decreaſe of matter within the egg, from the time of its being laid, a fluid matter is continually perſpiring through theſe perforations of the ſhell, which occaſions the decay; and this is carried on in a much quicker manner in hot weather than in cold. To preſerve the egg freſh, there needs no more to be done than to preſerve it full, and ſtop its tranſpiration; and the plain and rational method of doing this, is by ſtopping up thoſe pores through which the matter tranſpires, with a matter which is not ſoluble in watery fluids, and therefore cannot be waſhed away by the matter perſpired by the egg; and on this principle, all kinds of varniſh, prepared with ſpirit of wine, will preſerve eggs freſh for a long time, if they are carefully rubbed all over the ſhell. This might ſeem to moſt people a very common and cheap ſubſtance for this purpoſe: but the misfortune is, that in country places, where it ſhould be put in practice, no ſuch thing is to be had; and the poorer ſort of country people are not eaſily brought into the uſe of any thing to which they are not accuſtomed.

To obviate the difficulty ariſing from this, Mr. Reaumur thought of ſubſtituting in the place of varniſh ſome other ſubſtance more common; and ſoon found, that another ſubſtance, which is very cheap, and every where to be had, would very well ſupply the office of varniſh; for experiments proved, that any hard fat would have the ſame effect. The beſt of all fat for this purpoſe, is found to be a mixture of that of mutton and of beef; theſe ſhould be melted together over the fire, and ſtrained through a linen cloth into an earthen pan: and when thoroughly melted, an egg is to be dipped into it, and immediately taken out again; and it is then in a ſtate to keep perfectly freſh more than a twelvemonth. Memoirs Acad. Scienc. Par. 1735.

The only difficulty attending this method is, that the eggs cannot be ſo eaſily plunged into the fat, as that all their ſurfaces ſhall be covered by it; for if they are held in a pair of pincers, the parts of the egg where the pincers touch will be bare; but the eggs may be ſuſpended by a loop at the end of a thread, and by that means plunged in; and the thread being then coated over with the fat, as well as the ſurface of the egg, will preſerve that part which it covers as well as the coat of fat will the reſt. The great care is to uſe this means while the eggs are perfectly freſh; it ought indeed to be done on the very day when they are laid: for if the evaporation is begun, and the empty ſpace once made, there is room for a fermentation, which never terminates but in the deſtruction of the egg.

In Egypt they hatch their eggs by the heat of a furnace, or oven, and frequently have ſeven or eight thouſand chickens come forth at a time. An account of the method hereof we have in the Philoſophical Tranſactions. See Hatching.

Eggs *of Flies.* See Syſtem of Entomology.

EGYPTIANS, or *Gypſies*, in our ſtatutes, a kind of impoſters and jugglers, who diſguiſe themſelves in uncouth habits, ſmearing their faces and bodies, and framing to themſelves a canting language, wander up and down, and under pretence of telling fortunes, curing diſeaſes, &c. abuſe the common people, trick them of their money, and ſteal all that they can come at. There are ſeveral ſtatutes made againſt them. See Gypsies.

EJACULATOR, in anatomy, a name applied to two muſcles of the genitals, from their office in the ejaculation of the ſeed. The ejaculatores ariſe from the ſphincter of the anus, and advance along the urethra as far as the middle thereof, where they are inſerted laterally. The ſame denomination is likewiſe given to two muſcles of the clitoris, which ariſing from the ſphincter ani, advance laterally along the labia, and are inſerted aſide of the clitoris.

EJACULATORY, in anatomy, is a term applied to two little ducts, or canals, ariſing from the veſiculæ ſeminales. The ejaculatory ducts are about an inch in length: towards the veſiculæ, they are pretty wide; but they contract themſelves as they approach towards the urethra, which they penetrate together. Some authors alſo apply the name ejaculatory to the vaſa deferentia.

EJECTION, the act of throwing out, or diſcharging any thing at ſome of the emunctories, as by ſtool, vomiting, or the like.

Ejectione *Firmæ*, a writ that lies for the leſſee for years, who is ejected before the expiration of his term, either by the leſſor or a ſtranger.

EJECTMENT may be brought by a leſſor againſt the leſſee, for rent in arrears, or holding over his term, &c. Reg. Orig. 227. But ejectment is now become an action in the place of many real actions, as writs of right, formedons, &c. which are very difficult, as well as tedious and chargeable; and this is the common action for trying of titles, and recovering of lands, &c. illegally kept from the right owner. Though, where entry is taken away by deſcents, fines, and recoveries, diſſeiſins, &c. ejectments may not be brought; ſo that all titles cannot be tried by this action.

The method of proceeding in the action of ejectment is, to draw a declaration, and therein feign a leaſe, for three, five, or ſeven years, to him that would try the title; and alſo feign a caſual ejector or defendant; and then deliver the declaration to the ejector, who ſerves a copy of it on the tenant in poſſeſſion, and gives notice in writing at the bottom, for him to appear and defend his title; or that he, the feigned defendant, will ſuffer judgment by default, whereby the true tenant will be turned out of poſſeſſion; to this declaration the tenant is to appear, at the beginning of next term, by his attorney, and conſent to a rule to be made defendant, inſtead of the caſual ejector, and take upon him the defence; in which, he muſt confeſs leaſe, judgment, entry, and ouſter, and at the trial ſtand upon the title only: but in caſe the tenant in poſſeſſion does not appear, and enter into the ſaid rule in time, after the declaration ſerved, then, on affidavit being made of the ſervice of the declaration, with the notice to appear, the court will order judgment to be entered againſt the caſual ejector by default; and thereupon the tenant in poſſeſſion by writ *habere facias poſſeſſionem*, is turned out of his poſſeſſion. On the trial in ejectment, the plaintiff's title is to ſet forth from the perſon laſt ſeiſed in fee of the lands in queſtion, under whom the leſſor claims down to the plaintiff, proving the deeds, &c. and the plaintiff ſhall recover only according to the right which he has at the time of bringing his action. And here, another who had title to the land, upon a motion made for that purpoſe, may be defendant in the action, with the tenant in poſſeſſion, to defend his title; for the poſſeſſion of the lands is primarily in queſtion, and to be recovered, which concerns the tenant, and the title thereto is tried collaterally, which may concern ſome other.

By a late ſtatute, in all caſes between landlord and tenant, where half a year's rent ſhall be in arrear, the landlord, having lawful right to re-enter for non-payment, may ſerve a declaration in ejectment on the tenant, without a formal demand or reentry; or he may affix ſuch declaration on the door of the demiſed meſſuage, or notorious place of the lands, which ſhall be deemed a legal ſervice; and upon proof that half a year's rent was due before the declaration was ſerved, and no ſufficient diſtreſs on the premiſſes, the leſſor ſhall have judgment and execution; which if the leſſee ſuffer without paying the arrears and coſts, and without filing a bill in equity to be relieved within ſix months, he ſhall be barred from all relief, except by writ of error; and the leſſor ſhall hold the premiſſes diſcharged from the leaſe; but if the tenant or leſſee tender to the leſſor, or bring into court the rent in arrear, together with coſts, all farther proceedings ſhall ceaſe, and if the leſſee be relieved in equity, he ſhall enjoy the demiſed premiſſes according to his leaſe, without obtaining a new one. Stat. 4 Geo. II. cap. 28. and 11 Geo. II. cap. 19.

ELABORATION, the act of finiſhing or perfecting any thing with labour and time. The term is chiefly uſed in medicine, where the chyle, blood, and ſemen, are ſaid to be well elaborated, when they are well conditioned, have undergone all the ſecretions, mixtions, impregnations, and circulations, neceſſary to bring them to perfection. If the chyle went directly from its receptaculum to the breaſts, it would not be ſufficiently elaborated to afford good milk.

ELABORATORY. See Laboratory.

ELÆOCARPUS, in botany, oleaſter or wild olive. A genus of the monogynia order, belonging to the tetrandria claſs of plants.

ELASMIS, in foſſiology, the name of a genus of foſſil bodies, of the talc claſs, the diſtinguiſhing characters of which are, that they are compoſed of ſmall plates, in form of ſpangles, each of which is either ſingle, and not farther fiſſile; or, if complex, only to a certain degree, and that into ſomewhat thick laminæ. The word is derived from the Greek ἐλασμος, *a lamina*, or *plate*: the ſeveral component parts of theſe maſſes being ſo many ſmall plates. See Syſtem of Fossilogy.

ELASTICITY, or Elastic *Force*, that property of bodies wherewith they reſtore themſelves to their former figure, after any external preſſure. The cauſe or principle of this important property elaſticity, or ſpringineſs, is variouſly aſſigned. The Carteſians account for it from the materia ſubtilis making an effort to paſs through pores that are too narrow for it. Thus, ſay they, in bending, or compreſſing, a hard elaſtic body, e. gr. a bow, its parts recede from each other on the convex ſide, and approach on the concave; conſequently the pores are contracted or ſtraitened on the concave ſide: and if they were before round, are now, for inſtance, oval; ſo that the materia ſubtilis, or matter of the ſecond element, endeavouring to paſs out of thoſe pores thus ſtraitened, muſt make an effort, at the ſame time, to reſtore the body to the ſtate it was in when the pores were more patent and round, i. e. before the bow was bent: and in this conſiſts its elaſticity.

Other later and more wary philoſophers account for elaſticity much after the ſame manner as the Carteſians; with this only difference, that in lieu of the ſubtile matter of the Carteſians, theſe ſubſtitute ether, or a fine etherial medium that pervades all bodies. Others, ſetting aſide the precarious notion of a materia ſubtilis, account for elaſticity from the great law of nature attraction, or the cauſe of the coheſion of the parts of ſolid and firm bodies. Thus, ſay they, when a hard body is ſtruck or bent, ſo that the component parts are moved a little from each other, but not quite disjoined or broke off, or ſeparated ſo far as to be out of the power of that attracting force whereby they cohere; they muſt certainly, on the ceſſation of the external violence, ſpring back to their former natural ſtate.

Others reſolve elaſticity into the preſſure of the atmoſphere: for a violent tenſion, or compreſſion, though not ſo great as to ſeparate the conſtituent particles of bodies far enough to let in any foreign matter, muſt yet occaſion many little vacuola between the ſeparated ſurfaces; ſo that upon the removal of the force they will cloſe again, by the preſſure of the aerial fluid upon the external parts.

Laſtly, others attribute the elaſticity of all hard bodies to the power of reſilition in the air included within them; and ſo make the elaſtic force of the air the principle of elaſticity in all other bodies.

The **Elasticity** *of Fluids* is accounted for from their particles being all endowed with a centrifugal force; when Sir Iſaac Newton, prop. 23. lib. 2. demonſtrates, that particles, which mutually avoid or fly off from one another by ſuch forces as are reciprocally proportioned to the diſtances of their centre, will compoſe an elaſtic fluid, whoſe denſity ſhall be proportional to its compreſſion; and *vice verſa*, if any fluid be compoſed of particles that fly off and avoid one another, and hath its denſity proportional to its compreſſion, then the centrifugal forces of thoſe particles will be reciprocally as the diſtances of their centres.

Elasticity *of the Air* is the force wherewith that element dilates itſelf, upon removing the force whereby it was before compreſſed. The elaſticity or ſpring of the air was firſt diſcovered by Galileo. Its exiſtence is proved by this experiment of that philoſopher: an extraordinary quantity of air being intruded by means of a ſyringe into a glaſs or metal ball, till ſuch time as the ball, with this acceſſion of air, weigh conſiderably more in the balance than it did before; upon opening the mouth thereof, the air ruſhes out, till the ball ſinks to its former weight. From hence we argue, that there is juſt as much air gone out, as compreſſed air had been crowded in. Air, therefore, returns to its former degree of expanſion, upon removing the force that compreſſed or reſiſted its expanſion; conſequently it is endowed with an elaſtic force. It muſt be added, that as the air is found to ruſh out in every ſituation or direction of the orifice, the elaſtic force acts every way, or in every direction. The elaſticity of the air makes a conſiderable article in Pneumatics.

The cauſe of the elaſticity of the atmoſphere hath been commonly aſcribed to a repulſion between its particles; but this can give us only a very ſlight idea of the nature of its elaſticity. The term repulſion, like that of attraction, requires to be defined, and in all probability will be found in moſt caſes to be the effect of the action of ſome other fluid. Thus, we find, that the elaſticity of the atmoſphere is very conſiderably affected by heat. Thus, ſuppoſing a quantity of air heated to ſuch a degree as is ſufficient to raiſe Fahrenheit's thermometer to 212, it will then occupy a conſiderable ſpace. If it is cooled to ſuch a degree as to ſink the thermometeter to 0, it will ſhrink up into leſs than half the former bulk. The quantity of repulſive power therefore acquired by the air, while paſſing from one of theſe ſtates to the other, is evidently owing to the heat added to or taken away from it. Nor have we any reaſon to ſuppoſe, that the quantity of elaſticity or repulſive power it ſtill poſſeſſes is owing to any other thing than the fire contained in it. The ſuppoſing repulſion to be a primary cauſe independent of all others, hath given riſe to many erroncous theories, and been one very great means of embarraſſing philoſophers in their accounting for the phenomena of Electricity.

ELATER, in entomology, a genus of inſects, belonging to the order of coleoptera. The feelers are ſetaceous. There are 38 ſpecies, diſtinguiſhed by their colour, &c. See Syſtem of Entomology.

ELATINE, in the Linnæan ſyſtem of botany, a genus of plants of the octandria tetragynia claſs.

ELBOW, the outer angle made by the flexure, or bend of the arm. That eminence whereon the arm reſts, called by us *elbow*, by the Latins called *cubitus*, and the Greeks *αγκων*, and by others *ολεκρανον*.

Elbow is alſo uſed by architects, maſons, &c. for an obtuſe angle of a wall, building, or road, which diverts it from its ſtraight line.

ELDER, a word uſed in ſome parts of the kingdom for fuel. Dict. Buſt.

Elder or **Alder** *Tree*, the Engliſh name of the genus, ſambucus, in botany. See Sambucus.

ELDERS, *Seniors*, in the Jewiſh hiſtory, were the moſt conſiderable perſons, for age, experience, and virtue, among the antient people. Moſes, we read, aſſembled the *elders* of the people together, and acquainted them with what the Lord had commanded.

Long afterwards, thoſe who held the firſt rank in the ſynagogues were uſually called זקנים, *zekenim*, *elders*, in imitation of the ſeventy *elders* whom Moſes eſtabliſhed for the judges of the ſanhedrim. Numbers xi. 16, 17, 24, 25. Exod. xxiv. 1, 9, 14. See Sanhedrim.

The preſident, or chief had, in a particular manner, the appellation of *elder*; being, as it were the *decanus ſeniorum*, *dean of the elders*.

In the aſſemblies of the primitive Chriſtians, thoſe who held the firſt place, or rank, aſſumed the denomination of preſbyters, or *elders*; for the word *preſbyters*, which occurs ſo frequently in the Old Teſtament, and which includes alike both biſhops and prieſts, does properly ſignify *elders*. See M. Simon's obſervation thereon, in his Supplement aux Ceremonies des Juifs.

The preſident, or biſhop, as being the chief of the *elders*, did likewiſe aſſume the denomination of *elder*; whence it is, that in the New Teſtament the name *biſhop* is frequently confounded with that of *preſbyter*. See Bishop, and Presbyter.

For the like reaſon, the council of the firſt churches was called *preſbyterium*, or council of the *elders*, where the biſhop precided in quality of firſt *elder* being ſeated in the middle of the other *elders*. The prieſts, or *elders*, who ſat by him, had each his judge's chair; for which reaſon they are called, by the fathers, *aſſeſſores epiſcoporum*. Nothing of any importance was done till it had firſt been examined, and reſolved, in this aſſembly, where the biſhop only made one body with the other *elders*, or prieſts; the juriſdiction which we now call epiſcopal, not being then dependent on the biſhop alone, but on all the *elders*, over whom he was only the preſident.

Elders is alſo a denomination ſtill retained in the preſbyterian diſcipline.

The *elders* are officers, who, in conjunction with the paſtors, or miniſters, and deacons, compoſe the conſiſtories, or kirk ſeſſions, meeting to conſider, inſpect, and regulate matters of religion and diſcipline. They are choſen from among the people, and are received publicly with ſome degree of ceremony. In Scotland, there is an indefinite number of *elders* in each pariſh; generally about twelve. See Presbytery.

ELECT, from *eligo*, *I chuſe*, *choſen*, in the *Scripture*, is applied to the primitive Chriſtians. In which ſenſe, the *elect* are thoſe choſen and admitted to the favour and bleſſing of Chriſtianity.

Elect, in ſome ſyſtems of theology, is a term appropriated to the ſaints, or the predeſtinated. In which ſenſe, the *elect* are thoſe perſons who are ſaid to be predeſtinated to glory as the end, and to ſanctification as the means.

Elect is likewiſe applied to archbiſhops, biſhops, and others officers, who are choſen, but not yet conſecrated, or actually inveſted with their office, or juriſdiction. The emperor is ſaid to be *elect*, before he is inaugurated and crowned; a lord mayor is *elect* before his predeceſſor's mayoralty is expired, or the ſword is put in his hands.

ELECTION, a choice made of any thing, or perſon, whereby it is preferred to ſome other. There ſeems this difference, however, between choice and election, that election has uſually regard to a company or community, which makes the choice; whereas choice is ſeldom uſed, but when a ſingle perſon makes it.

Election is alſo the ſtate of a perſon who is left to his own free will, to take or do either one thing, or another, which he pleaſes.

Election, in theology, ſignifies the choice which God, of his good pleaſure, makes of angels or men, for the objects of mercy and grace. The election of the Jews, was the choice God made of that people to be more immediately attached to his worſhip and ſervice, and for the Meſſiah to be born of them. And thus particular nations were elected to the participation of the outward bleſſings of Chriſtianity.

Election alſo, in the language of ſome divines, ſignifies a predeſtination to grace and glory, and ſometimes to glory only. And it has been enjoined as an article of faith, that predeſtination to grace is gratuitous, merely and ſimply ſo; *gratia, quia gratis data*. But the divines are much divided as to the point, whether election to glory be gratuitous, or whether it ſuppoſes obedience and goods works, i. e. whether it be before, or after, the previſion of our obedience.

Election, in Britiſh polity, is the people's choice of their repreſentatives in parliament. In this conſiſts the exerciſe of the democratical part of our conſtitution: for in a democracy there can be no exerciſe of ſovereignty but by ſuffrage, which is the declaration of the people's will. In all democracies, therefore, it is of the utmoſt importance to regulate by whom, aud in what manner, the ſuffrages are to be given. And the Athenians were ſo juſtly jealous of this prerogative, that a ſtranger, who interfered in the aſſemblies of the people, was puniſhed by their laws with death; becauſe ſuch a man was eſteemed guilty of high treaſon, by uſurping thoſe rights of ſovereignty to which he had no title. In Britain, where the people do not debate in a collective body, but by a repreſentation, the exerciſe of this ſovereignty conſiſts in the choice of repreſentatives. The laws have therefore very ſtrictly guarded againſt uſurpation or abuſe of this power, by many ſalutary proviſions; which may be reduced to theſe three points. The qualifications of the electors. The qualifications of the elected; and the proceedings at elections.

The reaſon of requiring any qualification, with regard to property, in voters, is to exclude ſuch perſons as are in ſo mean a ſituation, that they are eſteemed to have no will of their own. If theſe perſons had votes, they would be tempted to diſpoſe of them under ſome undue influence or other. This would give a great, an artful, or a wealthy man, a larger ſhare in elections than is conſiſtent with general liberty. If it were probable that every man would give his vote freely, and without influence of any kind; then, upon the true theory and genuine principles of liberty, every member of the community, however poor, ſhould have a vote in electing thoſe delegates, to whoſe charge is committed the diſpoſal of his property, his liberty, and his life. But, ſince that can hardly be expected, in perſons of indigent fortunes, or ſuch as are under the immediate dominion of others, all popular ſtates have been obliged to eſtabliſh certain qualifications; whereby ſome, who are ſupected to have no will of their own, are excluded from voting, in order to ſet other individuals, whoſe wills may be ſuppoſed independent, more thoroughly upon a level with each other.

This conſtitution of ſuffrages is framed upon a wiſer principle, with us, than either of the methods of voting, by centuries or by tribes, among the Romans. In the method by centuries, inſtituted by Servius Tullius, it was principally property, and not numbers, that turned the ſcale: in the method by tribes, gradually introduced by the tribunes of the people, numbers only were regarded, and property entirely overlooked. Hence the laws paſſed by the former method had uſually too great a tendency to aggrandize the Patricians or rich nobles; and thoſe by the latter had too much of a levelling principle. Our conſtitution ſteers between the two extremes. Only ſuch are intirely excluded, as can have no will of their own: there is hardly a free agent to be found, but what is entitled to a vote in ſome place or other in the kingdom. Nor is comparative wealth, or property, entirely diſregarded in elections; for though the richeſt man has only one vote at one place, yet, if his property be at all diffuſed, he has probably a right to vote at more places than one, and therefore has many repreſentatives. This is the ſpirit of our conſtitution: not that we aſſert it is in fact quite ſo perfect as we have here endeavoured to deſcribe it; for, if any alteration might be wiſhed or ſuggeſted in the preſent frame of parliaments, it ſhould be in favour of a more complete repreſentation of the people.

As it is eſſential to the very being of parliament that elections ſhould be abſolutely free, therefore all undue influences upon the electors are illegal, and ſtrongly prohibited. For Mr. Locke ranks it among thoſe breaches of truſt in the executive magiſtrate, which, according to his notions, amount to a diſſolution of the government, "if he employs the force, treaſure, and offices of the "ſociety to corrupt the repreſentatives, or openly to pre-engage "the electors, and preſcribe what manner of perſons ſhall be "choſen: for thus to regulate candidates and electors, and new "model the way of election, what is it, (ſays he,) but to cut up "the government by the roots, and poiſon the very fountain of "public ſecurity?" As ſoon, therefore, as the time and place of election, either in counties or boroughs, are fixed, all ſoldiers quartered in the place are to remove, at leaſt one day before the election, to the diſtance of two miles or more; and not to return till one day after the pole is ended. Riots likewiſe have been frequently determined to make an election void. By vote alſo of the houſe of commons to whom alone belongs the power of determining conteſted elections, no lord of parliment, or lord lieutenant of a county, hath any right to interfere in the election of commoners; and, by ſtatute, the lord warden of the cinque ports ſhall not recommend any members there. If any officer of the exciſe, cuſtoms, ſtamps, or certain other branch of the revenue, preſumes to intermeddle in elections, by perſuading any voter, or diſſuading him, he forfeits 100l. and is diſabled to hold any office.

The firſt inſtance that occurs, of election bribery, was ſo early as 13 Eliz. when one Thomas Longe (being a ſimple man, and of ſmall capacity, to ſerve in parliament) acknowledged that he had given the returning officer and others of the borough for which he was choſen, four pounds to be returned member, and was for that premium elected. But for this offence the borough was amerced, the member was removed, and the officer fined and impriſoned. But as this practice hath ſince taken much deeper and more univerſal root, it hath occaſioned the making many ſtatutes; to complete the efficacy of which, there is nothing wanting but reſolution and integrity to put them in ſtrict execution.

Undue influence being thus guarded againſt, the election is to be proceeded to on the day appointed; the ſheriff or other returning officer firſt taking an oath againſt bribery, and for the due execution of his office. The candidates likewiſe, if required, muſt ſwear to their qualification, and the electors in counties to theirs; and the electors both in counties and boroughs are alſo compellable to take the oath of abjuration, and that againſt bribery and corruption. And it might not be amiſs, if the members elected were bound to take the latter oath, as well as the former; which, in all probability, would be much more effectual, than adminiſtring it only to the electors.

The election being cloſed, the returning officer in boroughs return his precept to the ſheriff, with the perſons elected by the majority: and the ſheriff returns the whole, together with the writ for the county and the knights elected thereupon, to the clerk of the crown in chancery; before the day of meeting, if it be a new parliament, or within 14 days after the election, if it be an occaſional vacancy; and this under penalty of 500l. If the ſheriff does not return ſuch knights only as are duly elected, he forfeits, by the old ſtatutes of Henry VI. 100l. and the returning officer in boroughs for a like falſe return, 40l. and they are beſides liable to an action, in which double damages ſhall be recovered, by the later ſtatutes of king William: and any perſon bribing the returning officer ſhall alſo forfeit 300l. But the members returned by him are the ſitting members, until the houſe of commons, upon petition, ſhall adjudge the return to be falſe and illegal. The form and manner of proceeding upon ſuch petition are now regulated by ſtatute 10 Geo. III. c. 16. (amended by 11 Geo. III. c. 42. and made perpetual by 14 Geo. III. c. 15.) which directs the method of chuſing by lot a ſelect committee of 15 members, who are ſworn well and truly to try the ſame, and a true judgment to give, according to the evidence. See PARLIAMENT.

Some benefices are elective, others collative. Municipal offices in England are generally elective; in Spain, venal. Poland is an elective kingdom. All prelatures in France are elective, ſince the Concordat.

ELECTOR, a perſon who has a right to elect, or chooſe another to an office, honour, &c. The word is formed of the Latin *eligere, to chooſe*. We ſay the electors of a burgeſs, a knight of the ſhire, a grand-maſter of an order, &c.

ELECTOR is particularly, and by way of eminence, applied to certain princes of Germany, in whom lies the right of electing the emperor, being all ſovereigns, and the principal members of the empire.

The firſt author who mentions the ſeven electors is Martinus Polonus, and this reſtrictive privilege was propably obtained by degrees. The princes of greater authority were firſt allowed to name the perſon whom they wiſhed to be choſen emperor, and the people retained the right of approving or diſapproving the nomination; and when they had ſecured the right of voting firſt, or of prætaxation, as it was called, it became needleſs for the inferior eccleſiaſtics or barons to attend, merely to confirm their choice; more eſpecially as their attendance would become troubleſome and expenſive. Beſides, the aſſumed privilege of the ſeven electors, who poſſeſſed the moſt extenſive terretories, was ſtrongly ſupported by their numerous dependants and allies; and they were conſidered as the repreſentatives of all the orders which compoſed the higheſt claſs of German nobility. See Robertſon's Hiſt. chap. v. vol. i. p. 458, &c. 8vo. edit.

The electors have not only the power of chuſing the emperor, but they have actually exerciſed that of depoſing him. Thus they depoſed Adolphus of Naſſau in 1298, and Wenceſlaus in 1401. The ſeveral functions of the electors are as follow: the election of Mentz is chancellor of Germany; he convokes the ſtates, and gives his vote before any of the reſt. The elector of Cologne is grand chancellor of Italy, and conſecrates the emperor. The elector of Treves is grand chancellor of the Gauls, and confers the impoſition of hands on the emperor. The count palatine of the Rhine is grand maſter of the imperial palace, and preſents the emperor with a globe at his coronation. The marquis of Brandenburgh is grand chamberlain, and puts the ring on the emperor's finger. The duke of Saxony is grand marſhal, and gives the ſword to the emperor. The king of Bohemia, who was anciently only duke, is grand butler, and puts Charlemagne's crown on the emperor's head. Laſtly the elector of Hanover, now king of Great Britain, is arch-treaſurer; though firſt elected under the title of ſtandard bearer of the empire.

The electoral prince is the eldeſt ſon of an elector, and the preſumptive heir of his dignity. Electors are always addreſſed under the title of electoral highneſſes. The electoral college, conſiſting of all the electors of the empire, is the moſt illuſtrious and auguſt body in Europe.

ELECTORAL *Crown* or *Coronet*. See Syſtem of HERALDRY, Plate V.

ELECTORATE, the dignity of an elector, with the territory, or dominions, to which that quality is annexed.

Though the cuſtom ordinarily be, in Germany, for the ſons of princes to ſhare their fathers lands and territories among them, thoſe whereto the electorate is annexed are not uſed to be divided, but paſs entire to the eldeſt ſon who ſucceeds to the electorate.

ELECTRICITY, in general, ſignifies the operations of a very ſubtile fluid, in moſt caſes inviſible, but which ſometimes becomes the object of our ſight and other ſenſes, diſcovering itſelf to be one of the chief agents employed in producing the phenomena of nature.

SYSTEM OF ELECTRICITY.

INTRODUCTION.

THE ſcience of electricity is now generally acknowledged to be uſeful and important; and there is great reaſon to think, that at a future period it will be looked up to as the ſource from whence the principles and properties of natural philoſophy muſt be derived. It's utility to man will not be inferior to it's dignity as a ſcience.

It has been our endeavour, in the following Syſtem, to collect and arrange, in a methodical and conciſe manner, the eſſential parts of electricity, by theſe means to render its application eaſy, pleaſant, and obvious to the practitioner; and by bringing together experiments of the ſame kind, make them mutually illuſtrate each other, and thus point out the ſtrength, or diſcover the weakneſs, of the theories that have been deduced from them. Though the nature and confined limits of our plan do not admit of a formal enumeration of every particular, yet, we truſt, we have not omitted any article that can convey important information, or facilitate improvement, in the knowledge of the ſcience.

Arts and ſciences, like kingdoms and nations, have each in their turn ſome happy period of glory and ſplendor, in which they more than ever attract the human attention, and, by caſting a ſtronger light than at other times, become the favourite object and purſuit of the age; but theſe periods are ſoon over, and a few years of luſtre and fame are often overbalanced by centuries of oblivion. From undergoing this fate, ſome ſciences are, however, excepted, which, owing to the vaſt and neceſſary extent of their uſe, and to the fruitfulneſs of their productions, are ever flouriſhing; and although once unknown, yet when fame had proclaimed their birth, or publiſhed their advancement, they never afterwards declined. Of this kind is Electricity, one of the moſt pleaſing and ſurpriſing among all the branches of natural philoſophy that ever were cultivated by man. This ſcience, after it began to ſhew the extent and generality of its power; after it was known to be one of the greateſt agents of nature; remained always in vogue, was profitably cultivated, irremittedly advanced, and is now brought to a ſtate, in which, inſtead of becoming ſterile, it ſeems further to engage the general attention, and to promiſe to its followers more munificent rewards. Optics, indeed, ſhews many enchanting and uſeful properties, but concerning viſion only; Magnetiſm exhibits the force of attraction, repulſion, and polarity in that ſubſtance called a Magnet: but Electricity, containing, as it were, all within its power, alone exhibits the effects of many ſciences, combines together different powers, and, by ſtriking the ſenſes in a particular and ſurpriſing manner, affords pleaſure, and is of uſe to the ignorant as well as the philoſopher, the rich as well as the poor. In Electricity, we are pleaſed with beholding its penetrating light, exhibited in numberleſs different forms; we admire its attraction and repulſion, acting upon every kind of body; we are ſurpriſed by the ſhock, terrified by the exploſion and force of its battery; but when we conſider and examine it as the cauſe of thunder, lightning, aurora borealis, and other appearances of nature, whoſe direful effects we can in part imitate, explain, and even avert, we are then involved in a maze, that leaves nothing to contemplate but the inexpreſſible and permanent idea of admiration and wonder.

It muſt appear ſurpriſing to every ſearcher after truth, that electricity, which is now allowed to be one of the principal agents employed in producing the phænomena of nature, ſhould have remained ſo long in obſcurity; for, comparatively ſpeaking, its exiſtence was not known to the ancients. They were not, indeed, altogether ignorant of the peculiar properties of thoſe bodies that we now term electrics *per ſe*; nevertheleſs their knowledge was circumſcribed, being confined to the obſervation only of thoſe phænomena which nature preſented to their ſenſes, in the ordinary courſe of her operations; hence near two thouſand years elapſed, before any addition was made to the little which was known to Theophraſtus, and this branch of natural hiſtory remained uncultivated, till the happy period arrived, when the philoſopher was emancipated from the chains of hypothetic reaſoning, and the uncertainties of vague conjecture.

The exiſtence of this ſubtle, and in moſt caſes inviſible, power, was then traced, and many of its properties developed; its agency was diſcovered to be univerſal, and its extent unlimited.

Electricity has been dignified in a peculiar manner, by engaging the attention of the philoſophic hiſtorian; who by delineating the gradual progreſs of its diſcoveries, deſcribing the different theories which have been invented to account for its effects, and pointing out the *deſiderata* which ſtill remain to be explored, has contributed, in a high degree, to enlarge the boundaries of electricity, and to increaſe the number of thoſe who cultivate it.

Since the publication of Dr. Prieſtley's hiſtory, the electrical apparatus has been conſiderably augmented, and many new experiments have been made. To deſcribe the one, and to arrange the other, under ſuch heads as will point out the connection between the experiments and the received theory of electricity, is the principle deſign of this Syſtem.

As electricity is in its infancy, when conſidered as a ſcience, its definitions and axioms cannot be ſtated with geometric accuracy. We ſhall endeavour to avoid, as much as poſſible, the uſe of poſitive expreſſion, in order to invite the reader to examine the experiments himſelf, to compare them one with another, and then draw his own concluſions; beginning with thoſe experiments which were the foundation of the preſent ſtate of electricity, and which gave riſe to the principal technical terms made uſe of in this ſcience.

In this Syſtem we ſhall firſt give a brief hiſtory of the ſcience, afterwards an account of its uſes, and then divide it into three parts, in each of which are contained ſuch particulars, as had leſs connection with the reſt; and the diſtinct view of which, it was thought, might be a means of preventing a confuſion of ideas in the minds of thoſe readers, who before have not been much converſant with the ſubject.

The firſt part treats of the laws of electricity only; i. e. of ſuch natural laws concerning electricity, as by innumerable experiments, have been found uniformly true, and are independent on any hypotheſis. In this part, we have not deſcended to particulars, which were not clearly aſcertained, or which were inconſiderable; but we have, at the ſame time, taken care not to omit any thing material, or which ſeemed to promiſe future diſcoveries.

The ſecond part contains the practical branch of electricity. Here we have taken care to inſert a deſcription of all the new improvements in the apparatus; which ſerve to leſſen the expence of it, and at the ſame time, to facilitate the performance of the experiments. As to the experiments themſelves, we have chiefly inſiſted on a few principal ones, which ſeemed moſt neceſſary to illuſtrate and confirm the laws of electricity.

The third part contains the practice of medical electricity, on which we have been rather copious in conſideration of its great importance and utility. To render the ſyſtem more intelligible and uſeful we have added two plates, the firſt repreſenting the machines, as made by Mr. Adams, of Fleet Street, in which are united all the late improvements of modern profeſſors; the ſecond contains a variety of apparatus neceſſary for philoſophical and entertaining experiments.

HISTORY OF ELECTRICITY.

The earlieſt account we have of any known electrical effect, is by the famous antient naturaliſt Theophraſtus, who flouriſhed about 300 years before the preſent era. He tells us that *amber* (whoſe Greek name is ηλεκτρον, and from whence the name *Electricity* is derived) as well as the *lyncurium*, has the property of attracting light bodies. This was all that was known of the ſubject, for about fifteen centuries after Theophraſtus; in which long period we find no mention in hiſtory of any perſon having made any diſcoveries, nor even any experiments in this branch of philoſophy; the ſcience remaining quite in the dark till the time of Wm. Gilbert, an Engliſh phyſician, whoſe work *de magnete*, which contains ſeveral electrical experiments, was publiſhed in the year 1600; and who, for his diſcoveries in this new and uncultivated field, may be juſtly deemed the father of Electricity. He obſerved, that the property of attracting light bodies, after rubbing,, was not peculiar to amber, or the *lyncurium*; but that many other bodies poſſeſſed it as well as amber. He mentions a great number of thoſe, together with many particulars, which, conſidering the ſtate of the ſcience at that time, may be deemed truly great and intereſting.

After Gilbert, the ſcience advancing, although by ſmall degrees, paſſed, as it were, from infancy to puerility; many an excellent philoſopher undertaking to examine nature in this walk: ſuch was Sir Francis Bacon, Mr. Boyle, Otto Guericke, Sir Iſaac Newton, and moſt of all Mr. Hawkeſbee, a perſon to whom we are much indebted for many important diſcoveries, and a real advancement of Electricity. Mr. Hawkeſbee was the firſt who obſerved the great electric power of glaſs; a ſubſtance, that, ſince his time, has been generally uſed by all Electricians, in preference to any other electric. He firſt remarked various appearances of the electric light, and the noiſe accompanied with it, together with a variety of phenomena relating to electric attraction and repulſion.

After Mr. Hawkeſbee, the ſcience of Electricity, however hitherto advanced, remained for above 20 years in a ſtate of quieſcence, the attention of philoſophers being at that time engaged in other philoſophical ſubjects, which, on account of the new diſcoveries of the incomparable Sir Iſaac Newton, were then greatly in repute. Mr. Grey was the firſt, after this period of oblivion, to bring the ſcience again to light. He, by his great diſcoveries, re-introduced it to the acquaintance of philoſophers, and from him the true flouriſhing era of Electricity may be ſaid to take date.

The number of Electricians that hath been daily multiplying ſince Mr. Grey, the diſcoveries made, and the uſe derived from thoſe, till the preſent time, are matters really worthy of attention, and deſerve to be admired by every lover of the ſciences, and well-wiſher to the human race.

Whoever would make himſelf acquainted with the particular tranſactions concerning thoſe advances, ſhould read the elaborate Hiſtory of Electricity compiled by the learned Dr. Prieſtley; we forebear making any long hiſtorical detail; this treatiſe being intended to give an account of the preſent ſtate of Electricity, in a methodical manner, and not an hiſtory of the ſame. We ſhall in general only obſerve, that although the ſcience had through the Indefatigable attention of ſo many ingenious perſons, and by the diſcoveries that were daily produced, excited the curioſity of philoſophers, and engaged their attention; yet, as the cauſes of any thing, whether ſmall or great, known or unknown, are ſeldom much attended to, if their effects are not ſtriking and ſingular; ſo Electricity had, till the year 1746, been ſtudied by none but Philoſophers. Its attraction could in part be imitated by a loadſtone; its light by a phoſphorus; and, in ſhort, nothing contributed to make Electricity the ſubject of the public attention, and excite a general curioſity, until the capital diſcovery of the vaſt accumulation of its power, in what is commonly called the *Leyden phial*, which was accidentally made in the memorable year 1745. This great diſcovery was made by Mr. Von Kleiſt, Dean of the Cathedral in Comin. See the third edition of Dr. Prieſtley's Hiſt. of Elect. Per. VIII. Sect. I. Then, and not till then, the ſtudy of Electricity became general, ſurpriſed every beholder, and invited to the houſes of Electricians a greater number of ſpectators, than were before aſſembled together to obſerve any philoſophical experiments whatſoever.

Since the time of this diſcovery, the prodigious number of Electricians, experiments, and new facts that have been daily produced from every corner of Europe, and other parts of the world, is almoſt incredible. Diſcoveries crouded upon diſcoveries; improvements upon improvements: and the ſcience ever ſince that time went on with ſo rapid a courſe, and is now ſpreading ſo amazingly faſt, that it ſeems as if the ſubject would be ſoon exhauſted, and Electricians arrive at an end of their reſearches; but, however, the *ne plus ultra* is, in all probability, as yet at a great diſtance, and the young Electrician has a vaſt field before him, highly deſerving his attention, and promiſing further diſcoveries, perhaps equally, or more important than thoſe already made.

USES OF ELECTRICITY.

Nature, ever wiſe and admirable in her actions, ſeems to follow a certain ſimilarity in her works with a conformity of operations, and, from the ſimpleſt to the moſt complicated of her objects, an analogy is obſervable, which, as it is wonderful to be conſidered, ſo it is inſtructive and uſeful. It is on account of this analogy, that whenever a diſcovery is made in any part of natural philoſophy; whenever a ſcience is advanced, we not only attain to the knowledge of that ſingle law, or particular ſcience, but at the ſame time acquire means in general of inveſtigating the operations of nature with ſomewhat more certainty and accuracy; and by purſuing that analogy we are enabled to make further diſcoveries, and to improve every branch of knowledge. How far electricity has contributed towards this purpoſe, we think is unneceſſary to be further proved, when its action has been ſhown to be ſo general, and ſo powerful, as to perform what no art can operate. But, beſides the field that electricity has opened for further diſcoveries, and the ſatisfaction of that curioſity, which before attended the contemplation of ſo many wonderful phenomena as have been explained by this ſcience, there are two great advantages derived from electricity; the one is a defence againſt the direful effects of lightning, and the other a remedy for many diſorders incident to the human body.

In order to guard edifices or ſhips from being damaged by lightning, it was judiciouſly propoſed, by Dr. Franklin, to raiſe a metallic conductor ſome feet above the higheſt part of the building, and continue it down the wall till it penetrated ſome feet into the ground; by this means the houſe could never receive any damage; for whenever the lightning ſhould happen to fall upon it, it is evident that the conductor, being of metal, and higher than any part of the building, would certainly attract it, and, by conducting it to the ground, hinder that building from receiving any damage; for it is known that electricity always ſtrikes the neareſt and beſt conductors that it meets with in its way.

The reaſonableneſs and truth of this aſſertion has been confirmed by numberleſs facts, and the practice of raiſing ſuch conductors has been found exceedingly uſeful, particularly in hot climates, where thunder ſtorms are very frequent, and the damages occaſioned by the ſame too often experienced.

In regard to the conſtruction of ſuch conductors, there have been ſome controverſies among electricians; and the moſt advantageous manner of uſing them has not, without a great many experiments, and but very lately, been aſcertained. Some philoſophers have aſſerted that ſuch conductors ſhould terminate in a blunt end, that they might the leſs invite the lightning from the cloud; for a blunt end will not attract electricity from ſo great diſtance as a ſharp point. But ſome other philoſophers have thought a pointed termination to be much preferable to a blunt one; and their aſſertion is founded on much better reaſoning.

On board ſhips a chain has often been uſed for this purpoſe, which, on account of its pliableneſs, has been found very convenient, and eaſy to be managed among the rigging of the veſſel; but as the electricity finds a great obſtruction in going through the ſeveral links, for which reaſon chains have been actually broken by the lightning, ſo their uſe has now been almoſt entirely laid aſide; and, in their ſtead, copper wires a little thicker than a gooſe-quill have been ſubſtituted, and found to anſwer very well. One of theſe wires ſhould be elevated two or three feet above the higheſt maſt in the veſſel; this ſhould be continued down the maſt, as far as the deck, where, by bending, it ſhould be adapted to the ſurface of ſuch parts, over which it may moſt conveniently be placed, and, by continuing it down the ſide of the veſſel, it ſhould be always made to communicate with the water of the ſea.

In regard to perſonal ſecurity, in caſe a thunder-ſtorm were to happen while a perſon is in a houſe not furniſhed with a proper conductor, it is adviſable not to ſtand near places where there is any metal, as chimnies, gilt frames, iron caſements, or the like; but to go into the middle of a room, and endeavour to ſtand or ſit upon the beſt non-conductor that can be found at hand, as an old chair, a ſtool, &c. "It is ſtill ſafer (ſays Dr. Franklin) to bring two or three mattraſſes or beds into the middle of the room, and, folding them up double, put the chair upon them; for, they not being ſo good conductors as the walls, the lightning will not chooſe an interrupted courſe through the air of the room and the bedding, when it can go through a continued better conductor, the wall. But where it can be had, a hammock or ſwinging bed, ſuſpended by ſilk cords, equally diſtant from the walls on every ſide, and from the cieling and floor above and below, affords the ſafeſt ſituation a perſon can have in any room whatever, and what indeed may be deemed quite free from danger of any ſtroke by lightning."

If a ſtorm was to happen whilſt a perſon is in the open fields, and far from any building, the beſt thing he can do is to retire within a ſmall diſtance of the higheſt tree or trees he can get at; he muſt by no means go quite near them, but ſhould ſtop at about fifteen or twenty feet from their outermoſt branches; for if the lightning ſhould fall thereabout, it will very probably ſtrike the trees; and in caſe a tree was to be ſplit, he is ſafe enough at that diſtance from it.

In regard to the other great uſe of electricity, viz. its application as a medicine, there have been many opinions *pro* and *contra*, and the reputation of medical electricity has been very dubious and fluctuating; owing to the exaggerations, the miſtakes, the prejudices, and the intereſt of thoſe who have adminiſtered it in phyſical caſes. But after many experiments, and after overcoming the rooted prejudice of ſeveral phyſicians againſt medical electricity, it has been clearly obſerved, that, when properly managed, it is an harmleſs remedy, which ſometimes inſtantaneouſly removes divers complaints, generally relieves and often perfectly cures various diſorders, ſome of which could not be removed by the utmoſt endeavours of phyſicians and ſurgeons. Electricity when properly managed, if it does not effect a cure, at leaſt it produces no bad effect; the few caſes in which it ſeems to have produced any harm, are of a doubtful nature.

PART I. THEORY.

SECT. I.

EXPLANATION OF TERMS PRINCIPALLY USED IN ELECTRICITY.

If a perſon, holding with one of his hands a clean and dry glaſs tube, rubs it with his other hand, alſo clean and dry, ſtroking it alternately upwards and downwards; and after a few ſtrokes, preſents to it ſmall light bits of paper, thread, metal, or any other ſubſtance, the rubbed tube will immediately attract them, and after a little time will repel them—preſently, attract them again; and ſo alternately contribute this attraction, and repulſion, for a conſiderable time. If this tube be rubbed in the dark, and, after having been rubbed, a finger be preſented to it at the diſtance of about half an inch, a lucid ſpark will be ſeen between the finger and the tube, accompanied with a ſnapping noiſe; the finger at the ſame time receiving a puſh, as if it was from air iſſuing with violence out of a ſmall pipe.

In this experiment, the attraction, repulſion, ſparklings, &c. are the effects of that unknown cauſe called electricity; and hence they are called electrical appearances. The glaſs tube itſelf is called the electric, and all thoſe bodies which are capable by any means to produce ſuch effects, are called electrics; and as the rubbing awakes, as it were, in them the power of producing electrical appearances, they are therefore ſaid to be excited by the rubbing. The hand, or any other body that rubs an electric, is called the rubber; and if, inſtead of the perſon rubbing the glaſs tube, a machine be conſtructed capable by any means to excite an electric, this will be an electrical machine.

If at the end of the tube oppoſite to that held by the hand, a wire of any length be tied, ſuſpending a metallic ball at its end, and the tube be excited as before, the metallic ball will, in this caſe, acquire all the properties of the excited tube, i. e. it will attract, ſparkle, &c. like the tube itſelf, the electric virtue paſſing through the wire to the ball; hence, the wire is ſaid to be a conductor of electricity; and all ſuch bodies as are capable to tranſmit the electric virtue, like the above-mentioned wire, are called conductors.

But if, inſtead of the wire, a ſilk ſtring be uſed in the above experiment, and the tube be excited as before, the ball in this caſe will not ſhew any ſigns of electricity; the ſilk ſtring not permitting the electric virtue to paſs from the tube to the ball: hence the ſilk ſtring in this caſe, and all thoſe ſubſtances through which the electric virtue cannot be tranſmitted, are called non-conductors.

A body reſting intirely upon non-conductors is ſaid to be inſulated;

lated; ſo in the laſt experiment, the metallic ball was inſulated; ſince it was ſuſpended intirely by the ſilk ſtring, which is a non-conductor. The bodies which are conductors, and thoſe which are non-conductors of electricity, together with their peculiar properties, as far as they are known, will be plainly laid down in the following ſection.

SECT. II.

ELECTRICS AND CONDUCTORS.

The firſt and principal maxim in electricity is, that all the known bodies in nature are divided into two claſſes, viz. electrics, and conductors; experiments ſhewing, that whatever ſubſtance is a conductor of electricity, cannot be excited, (hence conductors are alſo called non-electrics); and that whatever ſubſtance can be excited, is not a conductor, (hence electrics and non-conductors become ſynonymous terms; electrics are often alſo called *electrics per ſe*. This maxim, however, is not to be conſidered as ſtrictly true and general; for in reality we know of no ſubſtance that may be called a perfect electric, nor of any, that may be called a perfect conductor: the electric virtue finding ſome reſiſtance in going through the beſt conductors, and being in part tranſmitted through, or over the ſurface of moſt, and perhaps all the electrics. The leſs perfect conductor any ſubſtance is, the nearer it comes to the nature of an electric; and, on the other hand, the leſs perfect electrics come neareſt to the nature of conductors. The limits of thoſe two claſſes come ſo far one within the other, that there are many ſubſtances which may be actually excited, and at the ſame time are pretty good conductors. If the reader deſires to know thoſe ambiguous ſubſtances, he muſt ſeek for the worſt electrics among the electrics, and for the worſt conductors among the conductors, excepting ſuch on which the experiment cannot be tried, as fluids, powders, &c.

The two following liſts contain, in general, all the electrics and conductors, diſpoſed in the order of their perfection, beginning in each liſt with the moſt perfect of their claſs. In this order, however, the reader muſt not expect a great exactneſs; that being impracticable, when ſubſtances are ſet under general articles.

Electrics.

Glaſs, and all vitrifications, even thoſe of metals. All precious ſtones of which the moſt tranſparent are generally the beſt.

All reſins *, and reſinous compounds. — [* Under the name of reſins, we would be underſtood to mean all ſuch conſiſtent, oily, vegetable productions, as are inflammable, and not ſoluble in water; gum-lac, therefore, and all ſuch ſubſtances, improperly called gums, are alſo meant under this article. See MACQUER's Chymiſtry, vol. i. chap. 11.] —Amber. Sulphur. Baked wood. All bituminous ſubſtances. Wax. Silk. Cotton. All dry animal ſubſtances, as feathers, wool, hair, &c. Paper. White ſugar, and ſugar candy. Air. Oils. Calces of metals and ſemi-metals. The aſhes of animal and vegetable ſubſtances. All dry vegetable ſubſtances. All hard ſtones, of which the hardeſt are the beſt.

Many of the above mentioned ſubſtances, and perhaps all thoſe upon which the experiment can be made, when very hot, loſe their electric property, and become quite, though not equally good, conductors; ſo red hot glaſs, melted reſin, hot air, baked wood made very hot, &c. become conductors of electricity. But it is very remarkable, that the focus of a burning glaſs is not a conductor of electricity. It has been obſerved, that glaſs, eſpecially the hardeſt and beſt vitrified, is often a very bad electric, ſometimes being quite a conductor. The Abbé Nollet and others have made various experiments relative to this property of glaſs, but without determining intirely the cauſes which occaſion the difference. Glaſs veſſels, made for electrical purpoſes, are often rendered very good electrics by uſe and time, though they might be very bad ones when new. On the other hand, ſome glaſs veſſels, which had been long uſed for excitation, have ſometimes loſt their power almoſt intirely.

A glaſs veſſel, out of which the air has been exhauſted, on being rubbed, ſhews no ſigns of electricity upon its external ſurface, but all the electric power appears within the veſſel; and a glaſs tube, or globe, with the air condenſed in it, or full of ſome conducting ſubſtance, is incapable of being excited. But a ſolid ſtick of glaſs, of ſealing-wax, &c. may be excited.

Conductors.

Gold. Silver. Copper. Braſs. Iron. Tin. Quickſilver. Lead. Semi-metals. Ores, of which the beſt are thoſe that contain the metallic part in the greateſt quantity, and come neareſt to a metalline ſtate. Charcoal, made either of animal or of vegetable ſubſtances. The fluids of an animal body. All fluids, excepting air and oils. The effluvia of flaming bodies. Ice. Snow. Moſt ſaline ſubſtances, of which the metallic ſalts are the beſt. Stony ſubſtances, of which the hardeſt are the worſt. Smoke. The vapour of hot water. Electricity pervades alſo vacuum, or the abſence of air cauſed by an air pump, almoſt as freely as the ſubſtance of a good conductor.

Beſides theſe, all bodies, in which more or leſs of ſome of the above mentioned conductors are contained, are alſo proportionably conductors; thus, green vegetables, raw meat, &c. are conductors, on account of the fluids they contain.

From this principle it follows, that all electrics, before excitation, ſhould be well cleaned, dried, and ſome made even very hot, in order to free them from every humidity; otherwiſe they are ſo far from the nature of electrics, that they become actually conductors, on account of the moiſture which they contain within their pores, or upon their ſurfaces.

In regard to the conducting power of charcoal, it muſt be obſerved, that all charcoal will not conduct equally well, there being ſome that will hardly conduct at all; and ſometimes is in ſuch a ſtate, that it will aſſiſt the paſſage of a large quantity of electric fluid along its ſurface, when it will not conduct it any other way. This difference, however, is not occaſioned by the difference of the wood from which the coals are made, but by the degree of deat that is applied in the proceſs of making them; the beſt conhuctors being ſuch as have been expoſed to the greateſt heat. See Dr. Prieſtley's ſecond volume of Obſervations on different Kinds of Air, Sect. XIV.

Whether the piece of wood in the proceſs of coaling is ſuffered to flame, or not, is quite immaterial; and the continuance of the ſame degree of heat has no apparent effect with reſpect to the conducting power of the charcoal.

It will not be improper to obſerve in this place, the different changes from conductor to non-conductor, occaſioned in the ſame ſubſtance by different preparations. A piece of wood juſt cut from a tree is a good conductor; let it be baked, and it becomes an electric; burn it to a coal, and it is a good conductor again; laſtly, let this coal be redneed to aſhes, and theſe will be impervious to electricity. Such changes are alſo obſervable in many other bodies; and very likely in all ſubſtances there is a gradation from the beſt conductors to the beſt non-conductors of electricity.

SECT. III.

POSITIVE AND NEGATIVE ELECTRICITY..

The firſt of theſe two electricities, i. e. that poſſeſſed by the glaſs tube in two experiments, mentioned in the above Section, as it was thought to be the conſtant production of rubbed glaſs, was called the vitreous electricity; and the other, as it was firſt obſerved to be produced by reſinous ſubſtances was called the reſinous electricity. The vitreous electricity is alſo called poſitive or plus electricity, for a reaſon that will be conſidered in the courſe of this Syſtem; and the reſinous is called alſo negative or minus electricity. A body, therefore, poſſeſſed of the vitreous, poſitive, or plus electricity, is that which ſhews ſuch ſigns as the tube was ſaid to exhibit; and a body poſſeſſed of the reſinous, negative, or minus electricity, that is which ſhews ſuch ſigns as the inſulated perſon was ſaid to exhibit in the above-mentioned experiment.

In the following table may be ſeen what electricity will be excited in different bodies, when rubbed with different ſubſtances. Smooth glaſs, for inſtance, will be found by this table to acquire a poſitive electricity, when rubbed with any ſubſtance hitherto tried, except the back of a cat (by which we mean the ſkin of a cat while on the animal alive); rough glaſs, viz. glaſs, the poliſh of which has been deſtroyed by emery or otherwiſe, will be found to acquire the poſitive electricity, when rubbed with dry oiled ſilk, ſulphur, &c. and the negative, when rubbed with woollen cloth, the hand, &c. and ſo of the reſt.

The back of a cat	Poſitive	Every ſubſtance with which it has been hitherto tried.
Smooth glaſs	Poſitive	Every ſubſtance hitherto tried, except the back of a cat.
Rough glaſs*	Poſitive	Dry oiled ſilk, ſulphur, metals.
	Negative	Woolen cloth, quills, wood, paper, ſealing wax, white wax, the human hand.
Tourmalin	Poſitive	Amber, air †.
	Negative	Diamond, the human hand.
Hare's ſkin	Poſitive	Metals, ſilk, loadſtone, leather, hand, paper, baked wood.
	Negative	Other fine furs.
White ſilk	Poſitive	Black ſilk, metals, black cloth.
	Negative	Paper, hand, hares, weaſel's ſkin.
Black ſilk	Poſitive	Sealing wax.
	Negative	Hare's, weaſel's, and ferret's ſkin, loadſtone, braſs, ſilver, iron, hand.
Sealing wax	Poſitive	Metals.
	Negative	Hare's, weaſel's, and ferret's ſkin, hand, leather, woolen cloth, paper.
Baked wood	Poſitive	Silk.
	Negative	Flannel

* Glaſs may be made rough by rubbing it with ſand, or emery.

† i. e. By blowing with a pair of bellows upon it. By this means many Electrics may be ſenſibly excited, and ſome better if the air blown is hot; although, in both caſes, very little Electricity can be obtained.

The preceding table might have been much extended, had we choſen to bring into it all the minutiæ attending this matter as far as is known; but this we think unneceſſary, becauſe experiments of this kind are of ſo nice a nature, that they require the moſt ſcrupulous attention in making them; and their effects depend upon ſuch ſmall and variable circumſtances, that often the very ſame electric, rubbed with the ſame rubber, gives at one time ſigns of one electricity, and at another time ſigns of the contrary. A very little alteration in the ſurface, a different degree of dryneſs, and even a different application of the ſame ſubſtances, often occaſions a difference in the electricity. We ſhall only obſerve in general, that as far as may be deduced from the greateſt number of experiments, it appears, that when different ſubſtances are rubbed together, that whoſe electric power is the ſtrongeſt, in general, acquires the poſitive, and the other the negative electricity; and when two bodies, differing in the ſmoothneſs or roughneſs of their ſurfaces, are rubbed together, the ſmootheſt acquires the poſitive, and the rougheſt the negative electricity. Theſe two qualities are often to be conſidered both together; for, except the two bodies are of the ſame ſubſtance, as ſmooth and rough glaſs, white and black ſilk, &c. they generally differ in both, viz. they have not the ſame electric power, and at the ſame time their ſurfaces differ in ſmoothneſs. This rule, however, is not to be conſidered as a conſtant and general one: for, according to this principle, it ſhould ſeem that a piece of ſealing-wax, when rubbed with the hand, or paper, would acquire the poſitive electricity; but this is contrary to experience.

SECT. IV.

OF THE DIFFERENT METHODS OF EXCITING ELECTRICS.

Rubbing, as we obſerved before, is the general mean by which all electric ſubſtances that are at all excitable, may be excited. Whether they be rubbed with electrics of a different ſort, or conductors, they always ſhew ſigns of electricity, and in general ſtronger when rubbed with conductors, and weaker when rubbed with electrics. But beſides friction, there are other means by which ſome electrics may be cauſed to ſhew electric appearances: theſe are, by melting, or pouring a melted electric into another ſubſtance; by heating or cooling; and by evaporating or effervſcing. The particulars obſerved by uſing the firſt of theſe two methods are the following:

If ſulphur be melted in an earthen veſſel, and left to cool upon conductors: if taken out of the veſſel, when cold, it will be found ſtrongly electrical: but not all ſo, if it be left to cool upon electrics.

If melted ſulphur be poured into a veſſel of baked wood, it acquires a negative, and the wood a poſitive electricity; but if it be poured into ſulphur, or rough glaſs, it acquires no ſenſible electricity.

Melted wax, poured into glaſs, or wood, acquires a negative electricity, and leaves the glaſs or wood poſitive. But ſealing-wax poured into ſulphur, acquires a poſitive electricity, and leaves the ſulphur negative.

Chocolate, freſh from the mill, as it cools in the tin pans in which it is received, becomes ſtrongly electrical; when turned out of the pans, it retains for ſome time this property, but ſoon loſes it by handling. Melting it again in an iron ladle, and pouring it into the tin pans as at firſt, will for once, or twice, renew the power; but, when the maſs becomes very dry and powdery in the ladle, the electricity is revived no more by ſimple melting; but if then a little olive oil be added, and mixed well with the chocolate in the ladle, on pouring it into the tin pan, as at firſt, it will be found to have completely recovered its electric power. The above remark on chocolate, together with the method of reſtoring its power by means of olive oil, is a diſcovery of the late Mr. W. Henly, F. R. S.

Now that we are ſpeaking of melted electrics, it will not be improper to obſerve, that it ſometimes happens, that ſome electric ſubſtances, by being melted and left to cool, acquire an electrical power, which they retain for a conſiderable time, often for months together, eſpecially if they are preſerved free from dampneſs and duſt. Such effects have ſometimes induced electricians to think, that ſome bodies are poſſeſſed of a permanent or perpetual electricity, which is as inherent in their ſubſtance as the magnetic power of a loadſtone: in truth, however, no ſuch ſubſtance has yet been found; and although roſin, ſulphur, amber, ſilk, and ſome other electrics, ſhew ſigns of electricity for a conſiderable time after they have been rendered electrical, yet their power is continually diminiſhing till it quite vaniſhes. It is remarkable, however, that ſulphur, reſinous, bituminous ſubſtances, and ſilk, retain in general the electric power much longer than glaſs, or any other electrics; the reaſon may be, that they do not attract moiſture like glaſs and other ſubſtances, or perhaps becauſe they are more porous.

If a ſtick of ſealing-wax be broken into two pieces, the extremities that were contiguous will be found electrified, one poſitively, and the other negatively.

The property of exhibiting electrical phenomena, by means of heating and cooling, was firſt obſerved in a hard ſemi-pellucid foſſil, known under the name of Tourmalin. This ſtone is called *aſchentrickker* by the Dutch, from its property of attracting the aſhes, when laid near the fire. Linnæus calls it *lapis electricus*. See his Flora Zeylonica. The Tourmalin, which is generally of a deep red or purple colour, and ſeldom exceeds the ſize of a ſmall walnut, is common in ſeveral parts of the Eaſt Indies, and eſpecially in the iſland of Ceylon.

While kept in the ſame degree of heat, it ſhews no ſigns of Electricity, but it will become electrical by increaſing or diminiſhing its heat, and ſtronger in the latter than in the former circumſtance. An exceedingly ſmall variation of temperature is often ſufficient to render the Tourmalin ſenſibly electrical.

Its Electricity does not appear all over its ſurface, but only on two oppoſite ſides, which may be called its poles, and they are always in one right line with the center of the ſtone, and in the direction of its ſtrata; in which direction the ſtone is abſolutely opaque, though on the other, ſemitranſparent.

Mr. William Canton hath lately obſerved a very vivid light to appear upon the Tourmalin, while heating in the dark: he can by this determine, which end of the ſtone will be poſitive, and which negative. Further, when the ſtone is ſtrongly excited, it emits very ſtrong flaſhes from the poſitive to the negative end, in the dark. The Brazilian emerald, Mr. Canton has obſerved to have alſo this property of emitting light, whilſt heating in the dark: but we imagine that every other precious ſtone will ſhew it, if its electric power is ſufficiently ſtrong; ſince the light is a conſequence of the paſſage of a ſufficient quantity of electricity through the air, or other partly reſiſting medium.

Moſt of the above properties, which were firſt obſerved, and thought peculiar to the Tourmalin, have been found to belong to ſeveral hard precious ſtones; they being alſo made electrical by heating and cooling, and have their poſitive and negative ſides laying in the direction of their ſtrata or cryſtals; and, in ſhort, as far as has been obſerved, they have been found to act exactly like tourmalins; though ſome poſſeſs this property in a much higher degree than others.

The other method of producing electricity, namely, by evaporation, &c. was lately diſcovered by Mr. Volta; and it ſeems to open the way to an ample field of ſpeculation. This ingenious philoſopher diſcovered that the evaporation of water, and of ſome other fluids, and likewiſe that ſeveral effervſcences, generated electricity. His experiments ſeem to ſhew the generality of the following law, viz. that fluids, or bodies in general, when reduced in the form of vapour, become electrified poſitively, and leave the bodies, with which they were laſt in contact, electrified negatively; but, on the contrary, when the vapours are condenſed in the form of a fluid, then they become electrified negatively, and leave thoſe bodies, with which they were laſtly in contact, poſitively electrified. Farther explanations and exemplifications of this principle will be found in the practical part of this Syſtem.

We ſhall laſtly obſerve, in this ſection of excitation, that whenever an electric is rubbed with another inſulated ſubſtance, although it acquires an electric power, and ſhews electrical appearances, yet that power is very weak; aud in order to obtain a conſiderable electricity, it is neceſſary that the rubber ſhould have a regular communication with the earth, by means of good conductors.

SECT. V.

OF COMMUNICATING ELECTRICITY.

In the preceding ſections we have conſidered electricity no further than in reſpect to its quality; we have remarked the differences between the poſitive and the negative, and have noted which bodies, and by what means, they could acquire this property. But now a vaſt proſpect is opening to our view, full of extraordinary appearances; and we are to conſider in this ſection, not the mere kind of electricity, but its numerous effects. Under the title of Communicated Electricity, falls almoſt all that is known of the ſubject; the paſſage of this virtue from one body to another is what cauſes its light; by being communicated to other bodies, we ſee its attraction; by its quick tranſition it is that it melts meltals, deſtroys animal and vegetable life; and, in ſhort, it is by this communication that the ſcience is at all known and cultivated.

Whenever electricity is by any means ſuperinduced on a body, it is there confined only by electrics, and remains with that body a longer or a ſhorter time, according as the electrics that confine it are more or leſs perfect. A glaſs tube, for inſtance, when rubbed, acquires a quantity of that power, whatever it is, which we call electricity. That electricity remains, and is perceivable upon the glaſs, inſomuch as it is ſurrounded by the air, which is an electric; and as the air is in a more or leſs perfect electric ſtate, ſo that virtue is retained upon the glaſs longer or ſhorter. An excited glaſs tube, if kept in a dry and rather warm place, for inſtance, at ſome diſtance from a good fire, will continue electrified above twenty hours. And becauſe the air is never a perfect electric, therefore the excited tube can never preſerve the acquired electricity perpetually, but is continually imparting ſome of it to the contiguous air, or to the conducting particles that float in that element, till at laſt it quite loſes its power. If a finger, or any other conductor, be preſented towards an excited electric, it will receive a ſpark, and in that ſpark part only of the electricity of the electric; but why not all? Becauſe the excited electric, being a non-conductor, cannot convey the electricity of all its ſurface to that ſide, to which the conductor has been preſented. Hence, if a conducting ſubſtance be ſucceſſively preſented to different parts of an excited electric, it will receive at every approach a ſpark, without repeating the excitation, till all the power of that electric is exhauſted, and then a new excitation is neceſſary in order to revive it.

An inſulated conductor having received the electricity from an excited electric (in which ſtate it is ſaid to be electrified by communication) will act in every reſpect like the excited electric itſelf, except that, when it is touched by another conductor communicating with the earth, the former gives one ſpark to the latter, and by that diſcharges all its electricity. The reaſon why an electrified conductor loſeth its electricity all at once, when touched with another conductor communicating with the earth, and not part of it only, like the excited electric, is, becauſe the electricity belonging to the whole of the conductor is eaſily conducted through its own ſubſtance, to that ſide, to which the other conductor is preſented. This propoſition muſt be conſidered under ſome limitations, ariſing from various circumſtances; for inſtance, if the electrified conductor is very much extended, and is touched with an imperfect conductor, or for a very ſhort time, then it is not unlikely that ſome electricity will remain in it even after the ſpark. Hence it appears that, in general, the electricity diſcharged from an electrified conductor, is much more powerful, than when diſcharged from an electric; for the conductor may acquire a great quantity of electricity from an electric, by receiving ſpark after ſpark, and afterwards, if touched, will diſcharge it all at once, and not by little and little as it was received.

It is remarkable, in the caſe of points throwing off or receiving electricity, that a current of air is ſenſible at an electrified point, which is always in the direction of the point, whether the electricity is poſitive or negative. The electric ſpark, taken upon any part of a living animal body, cauſeth a diſagreeable ſenſation, which is more or leſs troubleſome, as the ſpark is ſtronger or weaker, and the part, upon which it is taken, is more or leſs delicate; and alſo according to the particular conſtitution of individuals. A pretty large quantity of electricity pervades the ſubſtance of a conductor of a conſiderable length, with a ſurpriſing and imperceptible velocity; but a ſmall quantity of it has been found to take ſome little time in paſſing through a long, and leſs perfect, conductor. Bodies poſſeſſed of the ſame electricity, whether poſitive or negative, repel each other. But bodies poſſeſſed of different electricities, attract each other; and there is no electric repulſion, but between bodies poſſeſſed of the ſame electricity; nor electric attraction, but between bodies poſſeſſed of different electricities, i. e. between bodies poſitively and bodies negatively electrified. This law, i. e. that there is no electric attraction, except between bodies poſſeſſed of different electricities, will, perhaps, appear paradoxical, upon obſerving, that an excited electric attracts ſmall bodies, which never were by any means made electrical before; but the paradox will ſoon vaniſh, if what has been ſaid above be conſidered, i. e. that when conductors, and indeed electrics too, come near an electrified body, they become actually poſſeſſed of a different electricity. But this will appear much clearer from the experiments that are to be mentioned hereafter.

Electricity, ſtrongly communicated to inſulated animal bodies, quickens their pulſe, and promotes their perſpiration. If it is communicated to inſulated fruits, fluids, and in general to every kind of bodies that are actually in a ſtate of evaporation, it alſo increaſeth that evaporation; and that in a greater or leſs degree, as thoſe bodies are more or leſs ſubject to evaporate of themſelves; as the veſſels, that contain the ſame, are conductors or electrics; and as they have a greater or leſs ſurface expoſed to the open air. Although it has been by ſome pretended, that electricity cauſed ſeveral ſubſtances to evaporate through the pores of glaſs and metals, yet that could never be obſerved, though many accurate experiments were made for that purpoſe; beſides, this pretended evaporation ſeems on all accounts exceedingly improbable.

By increaſing the perſpiration of vegetables, electricity promotes their growth; it having been found, after ſeveral accurate experiments, that ſuch plants, which have been often and long electrified, have ſhewed a more lively and forward appearance, than others of the ſame kind that were not electrified. It is ſaid by Mr. Koeſtlin to have been found, that negative electrization retards both animal and vegetable life. See his Latin Diſſertation on the effects of electricity upon ſome organic bodies.

We ſhall conclude this ſection with remarking, that if the face, or any part of the body, is preſented to an excited electric, or to a conductor ſtrongly electrified, it will feel as if a wind was blowing, or rather as if a ſpider's web was drawn over it; alſo, if the noſtrils are preſented to an excited electric, they will be affected by a ſmell, much reſembling that of phoſphorous; but communicated electricity does not occaſion any ſuch ſenſation, except when a large quantity of it does ſuddenly paſs from one body to another. If bodies are kept for ſome time within the electric effluvia when ſtrong, they will retain the ſmell that they acquire for a conſiderable time after.

SECT. VI.

OF CHARGED ELECTRICS, OR THE LEYDEN PHIAL.

That glaſs is an electric ſubſtance, was firſt diſcovered by Dr. Gilbert. It was for a long time, however, thought to poſſeſs but a very weak electric virtue; though now it is found to be one of the beſt, if not the very beſt electric as yet known. Notwithſtanding the many experiments made upon this ſubſtance, it is not yet aſcertained what kind of glaſs is moſt proper for electrical purpoſes. It has been obſerved, that the hardeſt and moſt completely vitrified glaſs is often a very bad electric, being ſometimes quite a conductor. Glaſs veſſels made for electrical purpoſes are often rendered fit for them by uſe and time, though very bad electrics when new. Mr. Bergman of Upſal ſays, that very often, when his glaſs globes could not be excited to a ſufficient degree of ſtrength, he lined them with a thin coating of ſulphur, and that then they gave a much ſtronger poſitive electricity than before. In Italy, and other places, according to Mr. Nollet, it is the cuſtom of electricians to put a coating of pitch or other reſinous matter on the inſide of their globes, which they ſay always makes them work well. He gives the preference to the cryſtal glaſs of England, Bohemia, &c. It ſeems doubtful, however, whether the common bottle glaſs does not anſwer equally well, or even better.

The moſt remarkable phenomenon producible by excited glaſs is that of the Leyden phial. It depends entirely upon the following property of glaſs, viz. that it is impoſſible to electrify the outſide of a glaſs poſitively, at leaſt, to any conſiderable degree, without at the ſame time electrifying the inſide of it negatively: in like manner, it is impoſſible to electrify the outſide negatively; without at the ſame time electrifying the inſide poſitively. It is alſo the nature of glaſs and all other electric ſubſtances, when once electrified either by excitation or communication, to part with their electricity very ſlowly and gradually. Thus, ſuppoſing a tube, cylinder, or plate of glaſs, to be highly electrified; if a finger is brought near any part of it, a ſpark will be felt to ſtrike the finger with a ſnapping noiſe. Part of the electricity will then be diſcharged from the glaſs, but not all. If the finger is brought near another part of the glaſs, a ſimilar ſpark will be again produced; and ſo on, by moving the finger to different parts of the glaſs, till all its electricity is exhauſted. It is the nature of conducting ſubſtances to diſcharge all their electricity at once, by a ſingle ſpark, if another conducting ſubſtance is brought near them. This being the caſe, therefore, it follows, that if every part of one ſide of a glaſs plate is covered over with a conducting ſubſtance, every point of the glaſs will give out its electricity to the conductor; and conſequently, if another conducting ſubſtance is brought near to that by which the glaſs is covered, the whole electric power in the glaſs ought to be diſcharged in one ſingle flaſh or large ſpark.

This would no doubt be the caſe, if it was poſſible to electrify the glaſs only on one ſide. But this is found to be impoſſible. No method hath yet been found of electrifying one ſide of a peice of glaſs poſitively, without electrifying the other negatively at the ſame time. There is therefore a neceſſity for taking off the electricity from both ſides of the glaſs at the ſame time. This can only be done by covering both ſides of the glaſs with a conducting ſubſtance, and, preſenting other conductors to both ſides at the ſame time. Then the electricity of both is diſcharged in an inſtant. A ſtrong ſpark is perceived between both ſides of the coated glaſs and the conducting ſubſtances; and if a perſon holds one in each hand, he will, at the inſtant of the diſcharge, feel a very diſagreeable ſenſation, which cannot well be deſcribed, in his arms and breaſt: and this is ſaid to be receiving the electric ſhock.

If, inſtead of preſenting a conducting ſubſtance to both ſides of the plate at once, a finger is preſented to one ſide, ſuppoſe that which is poſitively electrified, and another ſubſtance very highly electrified poſitively is preſented to the negative ſide of the glaſs, a like diſcharge will enſue, but the ſhock will be much gentler than in the former caſe, and probably the electricity of the glaſs will not be all diſcharged. If two conducting ſubſtances, inſulated, ſuppoſe two cylinders of metal fixed upon ſticks of ſealing wax, or ſuſpended by ſilk threads, are brought to the ſides of the coated glaſs at the ſame time; each of them will receive a ſpark of poſitive or negative electricity, according as the ſide to which it was applied is poſitively or negatively electrified. When the metallic cylinders are taken away, they will communicate the electricity they have received to other bodies; and if again applied to the coated glaſs, they will receive ſparks as before; and thus; the electricity of both ſides will be gradually diſcharged.

After the diſcharge has been once made, the glaſs is found in a ſhort time to recover its electricity, though in a ſmall degree. The ſide which was originally electrified poſitively, becomes electrified in the ſame manner the ſecond time, and ſo of the negative ſide. This ſecond electrification is called the *reſiduum* of a charge; and, where there is a large ſurface of coating glaſs, hath a very conſiderable degree of power. The ſame thing, which we have juſt now obſerved with regard to a flat ſurface of glaſs, takes place with tubes and phials, or glaſs veſſels of any kind; and it is always obſerved, that the thinneſt glaſs anſwers beſt for this purpoſe. The Leyden phial conſiſts of a glaſs phial, jar, or bottle, covered on the outſide and inſide with tin foil, yet leaving an interval of two or three inches at top, without any metallic covering, that the electricity of the one ſide may not be communicated to the other as faſt as it is collected. A more particular deſcription of it will be given when we ſpeak of the electric apparatus.

SECT. VII.

OF ATMOSPHERICAL ELECTRICITY.

Whoever has remarked the numerous properties of electricity already mentioned, and has conſidered their extenſive power, will, we doubt not, be greatly ſurprized, when he compares the ſtate, in which the ſcience remained half a century ago, with that in which it is at preſent; but his wonder will ſtill increaſe, when he is told that electricity is not only to be obſerved by rubbing an electric, or warming a tourmalin, but that it has been found to exiſt in the air, rain, and clouds: that thunder and lightning have been diſcovered to be its effects; and that, in ſhort, whatever has the appearance of fire, or of any thing extraordinary in the atmoſphere, and upon the earth, has been attributed to electricity.

That the effects of electricity bore a great reſemblance to thunder and lightning, had been ſeveral times remarked by philoſophers, and eſpecially by the Abbé Nollet; but that they ſhould actually be found to be effects of the ſame cauſe, and that the phenomena of electricity ſhould be imitated by lightning, or thoſe of lightning by electricity, was neither thought poſſible, nor ſuſpected, till the celebrated Dr. Franklin made the bold aſſertion; and the French philoſophers firſt, and afterwards Dr. Franklin, proved the fact by undeniable arguments in the year 1752.

The ſimilarity of lightning and electricity is not to be remarked in a few appearances only, but it is obſervable throughout all their numerous effects, and there is not a ſingle phenomenon of the one, but may be imitated by the other. Lightning deſtroys edifices, animals, trees, &c. lightning goes through the beſt conductors which it meets in its way, and, if its paſſage is obſtructed by electrics, or leſs perfect conductors, it rends them, and diſperſes them in every direction: lightning burns, and melts metals and other ſubſtances; a ſtroke of lightning often diſturbs the virtue of a magnet, and gives polarity to ferruginous ſubſtances; and all theſe effects, as has been obſerved above, may be produced by electricity. But, independent of the great ſimilarity exiſting between lightning and electricity, what fully proves their identity is, that the matter of lightning may be actually brought down from the clouds by mean of inſulated and pointed metallic rods, or by electrical kites, and with it any known electrical experiment may be performed.

Clouds, as well as rain, ſnow, and hail, that fall from them, are almoſt always electrified, but oftener negatively than poſitively; and the lightning, accompanied with the thunder, is the effect of the electricity, which, darting from a cloud, or a number of clouds, highly electrified, ſtrikes into another cloud, or elſe upon the earth; in which caſe it prefers the moſt lofty and pointed places, and by this ſtroke produces all thoſe dreadful effects, that are known to be occaſioned by lightning.

The air, at ſome diſtance from houſes, trees, maſts of ſhips, &c. is generally electrified poſitively, particularly in froſty, clear, or foggy weather; but how the air, the fogs, and the clouds become electrified, has not yet been clearly aſcertained, although ſeveral conjectures have been offered; excepting however the principle of the electricity produced by evaporation and condenſation.

After that electricity and the matter of lightning were found to be the ſame thing, philoſophers began to ſuſpect the action of electricity to be where it had before been leſs imagined, and not without reaſon endeavoured to reconcile to it ſeveral other natural appearances. The aurora borealis, or northern light, was ſoon attributed to electricity, on obſerving that by this that flaming light may be imitated, and that the aurora borealis, when very ſtrong, has been known to diſturb the magnetic needle, which is alſo an effect of electricity. The late Mr. Canton frequently collected electricity in a conſiderable degree, during the time of an aurora borealis. His apparatus for that purpoſe conſiſted of an inſulated fiſhing rod, erected on the top of his houſe, having a wire twiſted round. See Phil. Tranſ. vol. LIX. page 88.

The accentions, that are often ſeen in the atmoſphere (commonly called ſtfalling ſtars) are thought to be electrical appearances. The ſame is alſo ſuppoſed to be the cauſe of ſuch other meteors, like white clouds, that often appear by night-time, particularly in hot climates. Beſides thoſe phenomena, water-ſpouts, hurricanes, whirl-winds, and even earthquakes, have been attributed to electricity. But now, perhaps, the reader will think philoſophers too extravagant, in going ſo far with electricity. Such thoughts ſeem at firſt ſight to be extravagancies; but if it be conſidered, that they do not appear to contradict the known laws of nature, that they are not aſſertions abſolutely void of proofs, add that they are the thoughts of great philoſophers, we think, they may be admitted, at leaſt ſo far as to be tried on proper occaſions, and to be conſidered as the moſt plauſible conjectures yet offered in explanation of the moſt ſurpriſing phenomena of nature. For further conjectures, ſee Dr. Franklin's letters and Dr. Prieſtley's Hiſt. of Electricity.

PART II.

PRACTICAL ELECTRICITY.

Hitherto we have treated of electricity only theoretically, having noted what has been found uniformly certain relative to this ſubject, and having exhibited a view of the moſt propable conjectures offered in explanation of electrical appearances; but electricity being a ſcience, that requires a more practical management, than perhaps any other branch of natural philoſophy, it is neceſſary that we ſhould now treat of it practically, and give the beſt directions we are able, both in regard to the conſtruction of the neceſſary apparatus, and to the performance of the experiments, not only requiſite in proving the foregoing propoſitions, but ſuch alſo as are pleaſing and entertaining.

In this part of the ſyſtem the reader will perhaps find more novelty than he expects; for, conſidering the number of books that have been publiſhed on this ſubject, one would imagine that all the experiments poſſible to be exhibited with an electrical machine, and its appendages, have already been deſcribed. The caſe, however is much the contrary; for not only the old experiments have been diverſified, but a variety of new ones have been invented, and even the principal part of the apparatus has undergone ſeveral changes and improvements.

In order the more regularly to proceed in the deſcription of the electrical apparatus, it will not be improper to divide its parts into three claſſes; conſidering in the firſt, the inſtruments neceſſary to produce electricity; in the ſecond, thoſe proper to accumulate, retain, and employ it; and laſtly, thoſe neceſſary to meaſure its quantity, and aſcertain its quality.

The principal inſtrument to produce electricity, is the electrical machine, i. e. a machine capable by any means of exciting an electric, ſo as to produce electrical appearances. The conſtruction of thoſe machines, from their firſt invention to the preſent time, has undergone ſo many changes, and their forms have been ſo much varied, that it would be very difficult, and even tedious, to deſcribe thoſe only which are moſt frequently in uſe. Every maker, and almoſt every electrician, conſtructs his own machines in a manner different from the reſt; and, as new facts or long practice points out ſome imperfections, the electrician is ready to contrive a new method to correct the preceding errors. Indeed the rapid advance of the ſcience is moſtly owing to this change, and variety of conſtructions; for whether caſual, or deſigned, a new conſtruction has generally either produced ſome diſcovery of importance, or expoſed ſome defect in the apparatus, and management of the ſame.

That the reader may be left at the liberty of chooſing the form of his machine, we ſhall in the next Section, give a particular deſcription of ſome machines, that are the moſt uſeful, and which contain all the improvements hitherto made.

The principal parts of the machine are the electric, the moving engine, the rubber, and the prime conductor, i. e. an inſulated conductor, which immediately receives the electricity from the excited electric.

SECT. I.

ELECTRICAL MACHINES, WITH DIRECTIONS FOR EXCITING THEM AND KEEPING THEM IN ORDER.

As ſoon as the properties of electricity were in ſome meaſure developed, the philoſopher and the artiſt concurred in contriving and executing a variety of machines to excite and accumulate this extraordinary agent. The greater part of theſe have been laid aſide, in proportion as the ſcience advanced, and its boundaries were extended. We ſhall, therefore, only deſcribe that electrical machine which is now in general uſe, whoſe conſtruction is ſimple, and well adapted to produce the electric fluid in great quantities, and tranſmit it in full and continued ſtreams to the prime conductor.

That the operator may ſucceed in producing this effect, we ſhall firſt enumerate thoſe parts of the machine which acquire moſt attention; then deſcribe the machine itſelf, and afterwards give inſtructions to enable him to excite it powerfully.

The following are the parts of an electrical machine, which fall more immediately under the care of the electrician.

1. The electric, which is to be excited, as the glaſs cylinder.
2. The mechanical contrivances by which the electric is put in motion.
3. The cuſhion and its appendages.
4. The conductor or conductors.

Explanation of Plate I.

Fig. 1. repreſents an electrical machine made on the moſt approved conſtruction. It is mounted and uſed in the ſame manner as *Fig.* 5. and differs only in the mechaniſm by which the cylinder is put in motion.

The cylinder of the machine, *Fig.* 5. is turned round by means of the two wheels, which act on each other by a catgut band, as in *Fig.* 5.

The cylinder of the machine, which is repreſented in *Fig.* 1, is put in motion by a ſimple winch, which is leſs complicated than the multiplying wheel, and therefore not ſo liable to be out of order. Mr. Adams lately improved the machines made with a multiplying wheel, rendered them more durable, and not more liable to be put out of order than thoſe which turn only with a winch. Moſt practical electricians, however, prefer a machine which is moved by a multiplying wheel, as it fatigues the operator leſs than that which is moved by a ſimple winch; while at the ſame time a moderate

ate increaſe of velocity in the cylinder, augments the momentum of the electric fluid, and produces a greater quantity of it in the ſame time, and thus prevents its being abſorbed by the cuſhion. And further, when the machine is fixed to a table, the poſition of the lower multiplying wheel is more advantageous to the operator, giving him a greater power over the cylinder and fatiguing him leſs; it may alſo be turned with the right hand, which cannot be done conveniently with the other. It may be proper to remark, that thoſe with a ſimple winch are cheaper than thoſe with a multiplying wheel.

Fig. 1 and 5. ABC repreſent the bottom board of the machine. D and E, the two perpendicular ſupports, which ſuſtain or carry the glaſs cylinder FGHI.

The axis of the cap K paſſes through the ſupport D; on the extremity of this axis either a ſimple winch is fitted, as in *fig.* 1, or a pulley, as in *fig.* 5.

The axis of the other cap runs in a ſmall hole which is made in the top of the ſupport E.

OP is the glaſs pillar to which the cuſhion is fixed, T a braſs ſcrew at the bottom of this pillar, which is to regulate the preſſure of the cuſhion againſt the cylinder. This adjuſting ſcrew is peculiarly advantageous. By it the operator is enabled to leſſen or increaſe gradually the preſſure of the cuſhion, which it effects in a much neater manner than it is poſſible to do when the inſulating pillar is fixed on a ſliding-board, a method that diſgraces the maker.

On the top of the pillar OP is a conductor, which is connected with the cuſhion, which is called the negative conductor. In this figure the conductor is ſuppoſed to be fixed cloſe to the cuſhion, and to lie parallel to the glaſs cylinder. In *fig.* 1, it is brought forwards, or placed too near the handle, in order that more of it may be in ſight as at RS.

Q, *Fig.* 1, repreſents the poſitive prime conductor, or that which takes the electric fluid immediately from the cylinder, R the glaſs pillar by which it is ſupported and inſulated, and S a wooden foot or baſe for the glaſs pillar. In *fig.* 1. this conductor is placed in a direction parallel (which is the beſt poſition) to the glaſs cylinder; it may be placed in any poſition occaſionally, as is moſt convenient to the operator. In general, electrical machines are ſold with a ſingle conductor; though there are many experiments where two are convenient, and from ſome improvements lately made in the apparatus, they are rendered exceeding proper for experimental inquiries.

A DESCRIPTION OF AN INSTRUMENT WHICH, BY THE TURNING OF A WINCH, PRODUCES THE TWO STATES OF ELECTRICITY WITHOUT FRICTION OR COMMUNICATION WITH THE EARTH.

By Mr. WILLIAM NICHOLSON.

From the PHILOSOPHICAL TRANSACTIONS.

Read at the ROYAL SOCIETY, June 5, 1788.

TO SIR JOSEPH BANKS, BART. P. R. S.

SIR,

THE following account of the inſtrument I had the honour to ſhew to yourſelf and other philoſophical friends, in the month of March laſt, will, I hope, appear ſufficiently intereſting to be communicated to the learned ſociety, over which you ſo worthily preſide.

Plate I. *fig.* 2. repreſents the apparatus ſupported on a glaſs pillar 6½ inches long. It conſiſts of the following parts. Two fixed plates of braſs, A and C, are ſeparately inſulated and diſpoſed in the ſame plane, ſo that a revolving plate B may paſs very near them, without touching. Each of theſe plates is two inches in diameter; and they have adjuſting pieces behind, which ſerve to place them accurately in the required poſition. D is a braſs ball, likewiſe of two inches diameter, fixed on the extremity of an axis that carries the plate B. Beſides the more eſſential purpoſe this ball is intended to anſwer, it is ſo loaded within on one ſide, that it ſerves as counterpoiſe to the revolving plate, and enables the axis to remain at reſt in any poſition. The other parts may be diſtinctly ſeen in *fig.* 3. The ſhaded parts repreſent metal and the white repreſent varniſhed glaſs. ON is a braſs axis, paſſing through the piece M, which laſt ſuſtains the plates A and C. At one extremity is the ball D already mentioned; and the other is prolonged by the addition of a glaſs ſtick, which ſuſtains the handle L and the piece GH ſeparately inſulted. E, F, are pins riſing out of the fixed plates A and C, at unequal diſtances from the axis. The croſs-piece GH, and the piece K, lie in one plane, and have their ends armed with ſmall pieces of harpſichord-wire, that they may perfectly touch the pins EF in certain points of the revolution. There is likewiſe a pin I, in the piece M, which intercepts a ſmall wire proceeding from the revolving plate B.

The touching wires are ſo adjuſted, by bending, that when the revolving plate B is immediately oppoſite the fixed plate A, the croſs-piece GH connects the two fixed plates, at the ſame time that the wire and pin at I, form a communication between the revolving plate and the ball. On the other hand, when the revolving plate is immediately oppoſite the fixed plate C, the ball becomes connected with this laſt plate, by the touching of the piece K againſt F; the two plates, A and B, having then no connection with any part of the apparatus. In every other poſition the three plates and the ball will be perfectly unconnected with each other.

Mr. Cavallo's diſcovery, ſo well explained in the laſt Bakerian Lecture, that the minute differences of electrization in bodies, whether occaſioned by art or nature, cannot be completely deſtroyed in any definite time, may be applied to explain the action of the preſent inſtrument. When the plates A and B are oppoſite each other, the two fixed plates A and C may be conſidered as one maſs; and the revolving plate B, together with the ball D, will conſtitute another maſs. All the experiments yet made concur to prove, that theſe two maſſes will not poſſeſs the ſame electric ſtate; but that, with reſpect to each other, their electricities will be plus and minus. Theſe ſtates would be ſimple and without any compenſation, if the maſſes were remote from each other; but as that is not the caſe, a part of the redundant electricity will take the form of a charge in the oppoſed plates A and B. From other experiments I find that the effect of the compenſation on plates oppoſed to each other, at the diſtance of one-fortieth part of an inch, is ſuch that they require, to produce a given intenſity, at leaſt one hundred times the quantity of electricity that would have produced it in either, ſingly and apart. The redundant electricities in the maſſes under conſideration will therefore be unequally diſtributed: the plate A will have about ninety-nine parts, and the plate C one; and, for the ſame reaſon, the revolving plate B will have ninety-nine parts of the oppoſite electricity, and the ball D one. The rotation, by deſtroying the contacts, preſerves this unequal diſtribution, and carries B from A to C, at the ſame time that the tail K connects the ball with the plate C. In this ſituation, the electricity in B acts upon that in C, and produces the contrary ſtate, by virtue of the communication between C and the ball; which laſt muſt therefore acquire an electricity of the ſame kind with that of the revolving plate. But the rotation again deſtroys the contact, and reſtores B to its firſt ſituation oppoſite A. Here, if we attend to the effect of the whole revolution, we ſhall find that the electric ſtates of the reſpective maſſes have been greatly increaſed: for the ninety-nine parts in A and in B remain, and the one part of electricity in C has been increaſed ſo as nearly to compenſate ninety-nine parts of the oppoſite electricity in the revolving plate B, while the communication produced an equal mutation in the electricity of the ball. A ſecond rotation will, of courſe, produce a proportional augmentation of theſe encreated quantities; and a continuance of turning will ſoon bring the intenſities to their maximum, which is limited by an exploſion between the plates.

If one of the parts be connected with an electrometer, more eſpecially that of Bennet, theſe effects will be very clearly ſeen. The ſpark is uſually produced by a number of turns between eleven and twenty; and the electrometer is ſenſibly acted upon by ſtill fewer. When one of the parts is occaſionally connected with the earth, or when the adjuſtment of the plates is altered, there are ſome variations in the effects, not difficult to be reduced to the general principles, but ſufficiently curious to excite the meditations of perſons the moſt experienced in this branch of natural philoſophy. An attention to brevity, however, renders it neceſſary to forbear enlarging upon them.

If the ball be connected with the lower part of Bennet's electrometer, and the plate A with the upper part, and any weak electricity be communicated to the electrometer, while the poſition of the apparatus is ſuch that the croſs-piece GH touches the two pins; a very few turns will render it perceptible. But here, as well as in the common doubler, the effect is rendered uncertain by the condition, the communicated electricity muſt be ſtrong enough to deſtroy and predominate over any other electricity the plates may poſſeſs. I ſcarcely need obſerve, that if this difficulty ſhould hereafter be removed, the inſtrument will have great advantages as a multiplier of electricity in the facility of its uſe, the very ſpeedy manner of its operation, and the unequivocal nature of its reſults.

I have the honour to be, &c.

W. NICHOLSON.

It is with great pleaſure, that we acquaint our readers, that they will find a further and full illuſtration of the Doubler, *Fig.* 2 and 3, Plate I. and of the electrometer, in a work that is preparing for the preſs, and will ſhortly be publiſhed, by the Rev. Mr. *Bennet*, F. R. S. entitled "New Experiments on Electricity;" and we are happy in having an opportunity of informing the lovers of this ſcience, that they will find a great variety of new, important and pleaſing experiments; and more ſo, that we have ſelected in our apparatus, inſtruments that will probably throw much new light on this intereſting branch of natural philoſophy.

LANE'S ELECTRICAL MACHINE, *Fig.* 4.

A, the cylinder; it is moved by means of a pulley, at the lower end of the axis, and a wheel B, which lies parallel to the table and revolves four times for every ſingle revolution of the wheel. The conductor C is finiſhed with points to collect the fire, and it is ſcrewed to the wire of a coated jar D, which ſtands in a ſocket between the cylinder and the wheel.

The electrometer applied to this machine conſiſts of braſs work, G, the lower parts of which is incloſed in the pillar F, made of wood, baked, and boiled in linced oil, and bored cylindrically about two thirds of its length; the braſs work is fixed to the pillar by the ſcrew H, moveable in the grove I, ſo that it may be raiſed higher or lower as the height of the jar, D, requires. Through the braſs work is made to paſs a ſteel ſcrew, L, the diſtance of whoſe threads is about one twenty fourth of an inch; to the end of which, and oppoſite to K, a poliſhed hemiſpherical piece of braſs fixed to the prime conductor, is fixed a well poliſhed ball of braſs, M. To this ſcrew is annexed a circular plate, O, divided into twelve equal parts, and in every revolution of this ſcrew, pointing to the diviſions of the ſcale N, each of which diviſion is equal to each turn of the ſcrew. The uſe of this electrometer is to diſcharge a jar, D, or any battery connected with the prime conductor, without a diſcharging rod; and to give ſhocks ſucceſſively of the ſame degree of ſtrength; and on this account it is particularly adapted for medical purpoſes. If a perſon holds a wire faſtened to the ſcrew H in one hand, and another wire fixed to E, a loop of braſs wire paſſing from the frame of the machine to a tin plate, on which the phial D, ſtands, he will perceive no ſhock when K and M are in contact; and the degree of exploſion, as well as the quantity of electricity decumulated in the phial, will be regulated by the diſtance of K and M from each other.

Fig. 5. Mr. Adams's Medical Electrical Machine, with the electrometer and bottle; *a b*, the electrometer; *c d*, the leyden bottle ſuſpended at a ſmall diſtance from it; a glaſs tube, *e f*, is fixed in this bottle.

It has been found more convenient, to ſeparate the electrometer from the bottle, and apply it to the conductor as in this figure. Where *a b*, repreſent the electrometer, *c d*, the leyden bottle, ſuſpended at a ſmall diſtance from it; a glaſs tube, *e f*, is fixed in this bottle, a ſmall part of the lower end of which is coated; two wires paſs through the ball C on the top of this tube, one of which goes down to the bottom of the exterior bottle, and touches its internal coating, the other only goes to the coating of the tube; theſe wires may be removed at pleaſure. The bottle is to be ſuſpended to the conductor by the ring, and a chain or wire to be fixed to the hook *d*, at the bottom.

We have not been ſo copious in our deſcription of the other parts of this machine as of *fig.* 1, it being nearly ſimilar, excepting the two wheels by which the cylinder is put in motion. This difference of the multiplying wheel is to be preferred as it excites more electric fluid and is leſs fatiguing to the operator.

Directions for Keeping Machines in Order.

Before the electrical machine is put in motion, examine thoſe parts which are liable to wear either from the friction of one ſurface againſt another, or to be injured by the dirt, that may inſinuate itſelf between the rubbing ſurfaces: ſuch as the axes which work in the wooden ſupports D E.

If any grating or diſagreeable noiſe is heard, the place from whence it proceeds muſt be diſcovered, wiped clean, and rubbed over with a ſmall quantity of tallow; a little ſweet oil or tallow ſhould alſo be occaſionally applied to the axis of the cylinder.

The ſcrews that belong to the frame ſhould be examined, and if they are looſe, they ſhould be tightened.

The different working parts of the machine having been looked into, and put in order, the glaſs cylinder, and the pillars which ſupport the cuſhion and conductor, ſhould be carefully wiped, to free them from the moiſture which glaſs attracts from the air, being particularly attentive to leave no moiſture on the ends of the cylinder, as any damp on theſe parts carries off the electric fluid, and leſſens the force of the machine.

Glaſs pillars have been ſometimes uſed to ſupport the cylinder, but they can be of no uſe, unleſs the foregoing circumſtance is conſtantly attended to; and if that is obſerved, they are ſuperfluous.

Take care that no duſt, looſe threads, or filaments adhere to the cylinder, its frame, the conductors, or their inſulating pillars; becauſe theſe will gradually diſſipate the electric fluid, and prevent the machine from acting powerfully.

Rub the glaſs cylinder firſt with a clean, coarſe, dry, warm cloth, or piece of waſh leather, and then with a piece of dry, warm, ſoft ſilk; do the ſame to all the glaſs inſulating pillars of the machine and apparatus; theſe pillars muſt be rubbed more lightly than the cylinder, becauſe they are varniſhed.

A hot iron may in ſome caſes be placed on the foot of the conductor, to evaporate the moiſture which would otherwiſe injure the experiments.

Before the machine be uſed, the cylinder ſhould be firſt wiped very clean with a ſoft linen cloth, that is dry, clean, and warm; and afterwards with a clean hot flannel, or an old ſilk handkerchief; this done, if the winch be turned, when the prime conductor, and other inſtruments, are removed from the electrical machine, and the knuckle be held at a little diſtance from the ſurface of the cylinder, it will be ſoon perceived that the electric fluid comes like a wind from the cylinder to the knuckle, and, if the motion be a little continued, ſparks, and crackling will ſoon follow. This indicates that the machine is in good order, and the electrician may proceed to perform his experiments. But if, when the winch is turned for ſome time, no wind is felt upon the knuckle, then the fault is, very likely, in the rubber.

Having thus fully deſcribed the electrical machines, we ſhall ſubjoin an account of the conſtruction of the conductors. When the conductor is of a moderate ſize, it is uſual to make it of hollow braſs; but when it is very large, then, on account of the price of the materials, it is made of paſteboard, covered with tin foil, or gilt paper. The conductor is generally made cylindrical; but let the form be what it will, it ſhould always be made perfectly free from points, or ſharp edges; and if holes are to be made in it, which on many accounts are very convenient, they ſhould be well rounded, and made perfectly ſmooth.

It has been conſtantly obſerved, that the larger the prime conductor is, the longer, and denſer ſpark can be drawn from it; and the reaſon of this is, that the quantity of electricity, diſcharged in a ſpark, is nearly proportional to the ſize of the conductor; on this account the prime conductor is now made much larger, than what was formely uſed. Its ſize, however, may be ſo large, that the diſſipation of the electricity from its ſurface, may be greater than what the electric can ſupply; in which caſe ſo large a conductor would be nothing more than an unwieldy, and diſagreeable incumbrance.

Beſides the electrical machine, the electrician ſhould be provided with glaſs tubes of different ſizes, a pretty large ſtick of ſealing wax, or a glaſs tube covered with ſealing wax, for the negative electricity. He ſhould at leaſt not be without a glaſs tube about three feet long, and one inch and a half in diameter. This tube ſhould be cloſed at one end, and at the other end ſhould have fixed a braſs cap with a ſtop cock, which is uſeful in caſe it ſhould be required to condenſe or rarify the air within the tube.

The beſt rubber for a tube of ſmooth glaſs is the rough ſide of black oiled ſilk, eſpecially when it has ſome amalgam rubbed upon it; but the beſt rubber for a rough glaſs tube, is a ſtick of baked wood, ſealing wax, or ſulphur.

Practical Method of exciting the Machines ſo as to produce a large Quantity of Electric Fluid.

On this ſubject we ſhall introduce the methods laid down by Mr. Adams, in his eſſay on electricity, page 34, &c.

In order to find out an effectual mode of exciting powerfully an electrical machine, it is neceſſary to frame ſome idea of the mechaniſm by which the cylinder extracts the electric fluid from the cuſhion, and thoſe bodies that are connected with it; I have, therefore, ſubjoined thoſe conjectures on which I have worked, and by which I have been able to excite, in the moſt powerful manner, the machines which have paſſed through my hands.

It appears to me, that the reſiſtance of the air is leſſened, or a kind of vacuum is produced, where the cuſhion is in cloſe contact with the cylinder; that the electric matter, agreeable to the law obſerved by all other elaſtic fluids, is preſſed towards that part where it finds leaſt reſiſtance; the ſame inſtant, therefore, that the cylinder is ſeparated from the cuſhion, the fire iſſues forth in abundance, becauſe the reſiſtance made to it by the action of the atmoſphere is leſſened at that part; a further circumſtance is alſo to be taken into this hypotheſis, namely, the effect which ariſes from the deſtruction of the attraction or coheſion between the cylinder and cuſhion. The more perfect the continuity is made, and the quicker the ſolution of it, the greater is the quantity which will proceed from the cuſhion. But as the fluid in this ſituation will enter with avidity every conducting ſubſtance that is near it, if any amalgam lies above that part of the cuſhion or rubber which is in contact with the cylinder, it will abſorb and carry back part of the electric fire to the reſervoir from whence it was extracted.

If theſe conjectures be true, to excite an electrical machine effectually, we muſt 1ſt, Find out thoſe parts of the cuſhion which are preſſed by the glaſs cylinder. 2d, Apply the amalgam only to thoſe parts. 3d, Make the line of contact between the cylinder and cuſhions as perfect as poſſible and 4th, Prevent the fire that is collected from eſcaping.

" About the year 1782, I applied a looſe flap of leather to the front of the cuſhion; the amalgam was ſpread over the whole of the flap; the cuſhion was then put in its place, and the looſe flap of leather doubled down, or rather turned in, more or leſs, till by ſucceſſive experiments that ſituation was diſcovered which produced the greateſt effect; for, by this means, the quantity of amalgam acting againſt the cylinder was leſſened, and the true line of contact in ſome meaſure aſcertained. Hence I was naturally led to contract the breadth of the cuſhion, and afterwards to place it in ſuch a manner that it might be eaſily raiſed or lowered.

" To find the line of contact formed between the cylinder and cuſhion, place a line of whiting, which has been previouſly diſſolved in ſpirits of wine, on the cylinder; on turning this round, the whiting is depoſited on the cuſhion, and marks thoſe parts of it which bear or rub againſt the cylinder. The amalgam is to be put only on thoſe parts, which are thus marked by the whiting; this line may alſo be aſcertained, by obſerving the parts of the cuſhion which gather the duſt from the cylinder, and laying the amalgam only on thoſe parts.

" The line of contact being found, and the amalgam placed on it, the cylinder is to be rubbed with a piece of leather which is covered with amalgam, which will render the contact between the cylinder and cuſhion more perfect, becauſe it fills the ſmaller pores of glaſs with amalgam, and depoſits the ſuperfluous particles on the cuſhion: it is alſo probable that the amalgam, thus depoſited on the ſurface of the glaſs, forms a continued ſeries of conducting particles, which carry the fire to the prime conductor, and will conſequently, under certain circumſtances, carry it back again to the cuſhion. When the cylinder is rubbed with the amalgamated leather, that part of the oil, or black ſilk, which lies above the cuſhion, is to be turned back, and if, by accident, any particles of amalgam ſtick to it, they muſt be wiped off carefully. If the machine has not been uſed for ſome time, it will be proper to place it for a few minutes, before a fire, and to take off the cuſhion and dry the ſilk thereof.

"If the electricity of the cylinder grows leſs powerful, it is eaſily renewed by turning back the ſilk which lies over it, and then rubbing the cylinder with the amalgamated leather, or by occaſionally altering the preſſure of the adjuſting ſcrew.

"A very ſmall quantity of tallow placed over the amalgam, is obſerved to give more force to the electric powers of the cylinder; the ſame end is anſwered by rubbing the cylinder with a coarſe cloth that has been greaſed a little, and afterwards wiping the cylinder with a clean cloth.

"When the cylinder is put into good action, a number of circular lines of fire will iſſue from the cuſhion; preſent a row of metallic points towards theſe, and they will diſappear. This ſhews, the conducting ſubſtance collects the electric fluid before it can take thoſe appearances, or be diſſipated into the air.

"Hence we learn, that to prevent a loſs of the electric fluid which his excited, we muſt prevent the air from acting on the fluid, which is put in motion by the excitation; becauſe the air not only reſiſts the emiſſion of the fluid, but alſo diſſipates what is collected on account of the conducting ſubſtances, which are continually floating in it.

"Theſe ends are effectually anſwered by letting a non-conducting ſubſtance, as a piece of black or oiled ſilk, proceed from the line or contact to the collecting points of the prime conductor, and placing theſe points within its atmoſphere. The ſtreams of fire, which proceed from the cuſhion over the cylinder, ſhew whether the cuſhion bears uniformly againſt the cylinder; for they are moſt copious and denſe at thoſe parts where the preſſure is greateſt, but are uniformly denſe, when the preſſure is equable.

"When the zinc amalgam is uſed, the ſilk will ſometimes adſo ſtrongly to the cylinder as to render it very difficult to turn; to obviate this, wipe the ſilk perfectly clean, and then rub it over with a very ſmall quantity of aurum muſivum, or a little whiting. The operator ought not to think his machine in good order till it pours forth the fire in great abundance, and ſtrong denſe ſparks are obtained in quick ſucceſſion from the conductor. When the conductor is removed, the fire ſhould ſparkle round the cylinder, and throw out many beautiful bruſhes of light.

"Two kinds of amalgam are much in requeſt at preſent. One is made of quickſilver five parts, zinc one part, which are melted together with a ſmall quantity of bees wax: the other is the aurum muſivum of the ſhops. I find it difficult, after many trials, to ſay which of theſe act the beſt. To make the amalgam adhere cloſely to the ſilk, it is neceſſary to greaſe it, wipe off the ſuperfluous greaſe, and then ſpread the amalgam."

Apparatus neceſſary to accumulate, retain, and employ Electricity.

The inſtruments neceſſary for the accumulation of electricity, are coated electrics, among which, glaſs coated with conductors obtains the principal place; on account of its ſtrength it may be formed into any ſhape, and it will receive a very great charge. The form of the glaſs is immaterial with reſpect to the charge it will contain; its thickneſs only is to be conſidered, for the thinner it is, the higher charge it is capable of receiving; but it is at the ſame time more ſubject to be broken by the force of electric attraction; for this reaſon, therefore, a thin coated jar or plate may be uſed very well by itſelf, and it is very convenient for many experiments; but when large batteries are to be conſtructed, then it is neceſſary to uſe glaſs a little thicker, and care ſhould be taken to have them perfectly well annealed. If a battery is required of no very great power, as containing about eight or nine ſquare feet of coated glaſs, we recommend the uſe of common pint, or half-pint phials, ſuch as apothecaries uſe. They may be eaſily coated with tin-foil, ſheet-lead, or gilt-paper on the outſide, and braſs-filings on the inſide; they occupy a ſmall ſpace, and, on account of their thinneſs, hold a very good charge. But when a large battery is required, then theſe phials cannot be uſed, for they break very eaſily; and for that purpoſe cylindrical glaſs jars, of about fifteen inches high, and four or five inches in diameter, are the moſt convenient. One large jar anſwers better than ſeveral ſmall ones, becauſe the diſſipation of the electric fluid over the uncoated part is not ſo conſiderable in the former as in the latter caſe. But then, if a large jar breaks, the loſs is much more conſiderable.

When glaſs plates or jars, having a ſufficient large opening, are to be coated, the beſt method is to coat them with tin-foil on both ſides, which may be fixed upon the glaſs with varniſh, gum-water, bees-wax, &c.; but in caſe the jars have not an aperture large enough to admit the tin-foil, and an inſtrument to adapt it to the ſurface of the glaſs, then braſs filings, ſuch as are ſold by the pin-makers, may be advantageouſly uſed, and they may be ſtuck with gum-water, bees-wax, &c. but not with varniſh, for this is apt to be ſet on fire by the diſcharge. Care muſt be taken that the coatings do not come very near the mouth of the jar, for that will cauſe the jar to diſcharge itſelf. If the coating is about two inches below the top, it will in general do very well: but there are ſome kinds of glaſs, eſpecially tinged glaſs, that, when coated and charged, have the property of diſcharging themſelves more eaſily than others, even when the coating is five or ſix inches below the edge. There is another ſort of glaſs, like that of which Florence flaſks are made, which, on account of ſome unvitrified particles in its ſubſtance, is not capable of holding the leaſt charge; on theſe accounts, therefore, whenever a great number of jars are to be choſen for a large battery, it is adviſeable to try ſome of them firſt, ſo that their quality and power may be aſcertained.

Electricians have often endeavoured to find ſome other electric, which might anſwer better than glaſs for this purpoſe, but we do not find that any remarkable diſcovery has been made relating to this point.

When a jar, a battery, or in general a coated electric, is to be diſcharged, the operator ſhould be provided with an inſtrument called the diſcharging rod, which conſiſts of a metal rod ſometimes ſtraight, but more commonly bended in the form of a C: they are made alſo of two joints, ſo as to open like a kind of compaſſes, as in *fig.* 25, Plate II. This rod is furniſhed with metal knobs at its extremities, and has a non-conducting handle, generally of glaſs or baked wood, faſtened to its middle. When the operator is to uſe this inſtrument, he holds it by the handle, and, touching one of the coated ſides of the charged electric with one knob, and approaching the other knob to the other coated ſide, or ſome conducting ſubſtance communicating with it, he completes the communication between the two ſides, and diſcharges the electric.

Apparatus to meaſure the Quantity, and aſcertain the Quality of Electricity.

They are commonly called electrometers; and are of four ſorts, 1ſt, the ſingle thread, 2d. the cork, or pith balls, 3d. the quadrant, and 4th. the diſcharging electrometer. The ſecond ſort of electrometer, i. e. the corkballs electrometer, was invented by Mr. Canton: the diſcharging electrometer was invented by Mr. Lane; See *Fig.* 4, Plate I. and another, on a different principle, by Mr. Kinnerſley: and the quadrant electrometer, which is of lateſt invention, is a contrivance of Mr. Henly. See *fig.* 14. A particular deſcription of this improved electrometer, will be found in other parts of the Syſtem.

Beſides the apparatus above deſcribed, there are ſeveral other inſtruments uſeful for various experiments, but theſe will be deſcribed occaſionally. The electrician however, ought to have by him not only a ſingle coated jar, a ſingle diſcharging rod, or in ſhort, only what is neceſſary to perform the common experiments; but he ſhould provide himſelf with ſeveral plates of glaſs, with jars of different ſizes, with a variety of different inſtruments of every kind, and even tools for conſtructing them; in order that he may readily make ſuch new experiments, as his curioſity may induce him to try, or that may be publiſhed by other ingenious perſons, who are purſuing their reſearches in this branch of philoſophy.

Practical Rules neceſſary to be obſerved by young Practitioners.

It often happens that young electricians are at a loſs to aſſign the reaſon, why ſome experiments do not ſucceed as deſcribed in the Syſtem on Electricity. Sometimes they are in poſſeſſion of very good inſtruments, but, by reaſon of ſome circumſtance or other unattended to, they are quite uſeleſs in their hands. This indeed cannot be remedied by nothing but practice, and it is by long uſe, that the electrician, as well as the practitioner in any art or ſcience, becomes ſo good an operator, as to uſe his inſtruments to the beſt advantage. A few rules are however very neceſſary, to guide him in his operations; and although theſe alone are inſufficient to make a perſon a complete practical electrician; yet, when accompanied with the actual management of the apparatus, they facilitate the uſe of it, and render the performance of the experiments more accurate and expeditious.

The firſt thing that the young electrician ſhould obſerve, is, the preſervation, and care, of his inſtruments. The electrical machine, the coated jars, and in ſhort every part of the electrical apparatus, ſhould be kept clean, and as free as poſſible from duſt, and moiſture. When the weather is clear, and the air dry, eſpecially in clear and froſty weather, the electrical machine will always work well. But when the weather is very hot, the electrical machine is not ſo powerful; nor in damp weather, except it be brought into a warm room; and the cylinder, the ſtands, the jars, &c. be made thoroughly dry.

If ſeveral jars are connected together, among which there is one that is apt to diſcharge itſelf very ſoon, then the other jars will alſo ſoon be diſcharged with that; although they may be capable of holding a very great charge by themſelves. The electrician muſt be cautious leſt, by ſome circumſtance not adverted to, the ſhock ſhould paſs through any part of his body; for an unexpected ſhock, though not very ſtrong, may occaſion ſeveral diſagreeable accidents. In making the diſcharge, care muſt be taken that the diſcharging rod be not placed on the thinneſt part of the glaſs, for that may cauſe the burſting of the jar.

When large batteries are diſcharged, jars will be often found broken in it, which burſt at the time of the diſcharge. To remedy this inconvenience, Mr. Nairne ſays he has found a very effectual method; which is, never to diſcharge the battery through a good conductor, except the circuit be at leaſt five feet long. Mr. Nairne adds, that ever ſince he made uſe of this precaution, he has diſcharged a very large battery near a hundred times, without ever breaking a ſingle jar, whereas before he was continually breaking them. But here it muſt be conſidered, that the length of the circuit weakens the force of the ſhock proportionably; the higheſt degree of which is in many experiments required.

"When a coated phial is cracked, either by a ſpontaneous diſcharge, or by any other accident, I remove the outſide coating from the fractured part, and then make it moderately hot by holding it to the flame of a candle, and whilſt it remains hot I apply burning ſealing wax to the part, ſo as to cover the fracture entirely; taking care that the thickneſs of the wax is rather more than the thickneſs of the glaſs. Laſtly, I cover all the ſealing wax, and alſo part of the ſurface of the glaſs beyond it, with a compoſition made with four parts of bees-wax, one of roſin, one of turpentine, and a very little oil of olives; which compoſition I ſpread upon a piece of oiled ſilk, and apply it in the manner of a plaiſter. With this method I have repaired ſeveral broken phials ſo effectually, that after being frequently charged, they were at laſt broken by a ſpontaneous diſcharge, but in a different part of the glaſs.

"Here it is proper to remark, that when jars, or glaſs in general, that is coated for the purpoſe of charging and diſcharging, is in any manner covered with cement or ſealing wax, it breaks more eaſily by a ſpontaneous diſcharge; and it is very remarkable that the fracture generally lies on the limits of the cement.

"It is adviſeable, when a jar, and eſpecially a battery, has been diſcharged, not to touch its wires with the hand, before the diſchaging-rod be applied to its ſides a ſecond, and even a third time; as there generally remains a reſiduum of the charge. This reſiduum is in great meaſure occaſioned by the electricity, that, when the jar is charging, ſpreads itſelf over the uncoated part of the glaſs near the coating, which will not be diſcharged at firſt, but gradually returns to the coating after the diſcharge, which is ſometimes very conſiderable.

"When any experiment is to be performed, which requires but a ſmall part of the apparatus, the remaining part of it ſhould be placed at a diſtance from the machine, the prime conductor, and even from the table, if that is not very large. Candles, particularly, ſhould be placed at a conſiderable diſtance from the prime conductor, for the effluvia of their flames carry off much of the electric fluid.

"Laſtly, the young electrician ſhould be cautioned not to depend on firſt appearances in electricity. A new phenomenon may juſtly excite his curioſity; it is laudable to remark it, and to perſue the hint; but at the ſame time even the doubtful aſſertion of a new fact ſhould never be made, till after a number of ſimilar and concurring experiments. Electricity is a ſcience that often deceives the ſenſes, and the moſt experienced electrician frequently finds himſelf miſtaken in things, which perhaps he may have before conſidered as the moſt certain."

SECT. II.

PHILOSOPHICAL AND ENTERTAINING EXPERMENTS.

Article I.

The Properties of Electric Attraction and Repulſion illuſtrated by Experiments on Light Bodies

Natural philoſophers were originally incited to conſider the nature of electricity from its ſtrong attractive and repulſive powers. The phænomena exhibited by thoſe myſterious properties are ſo various and ſo pleaſing, that they were led, as by enchantment, to purſue the ſubject; and have been richly rewarded by the diſcoveries, which are both intereſting and important.

The powers of genius have been exerted with induſtrious ardour to inveſtigate the cauſes of thoſe properties; but they are ſtill involved in deep obſcurity, and we are ſtill totally ignorant of that mechaniſm by which light bodies, when electrified, approach to or recede from each other.

To enter into a diſcuſſion of the difficulties which perplex this ſubject, would lead us too far from the deſign of this Syſtem; we ſhall, therefore, proceed to ſtate thoſe general properties, or modes of action, which are obſerved in electric attraction and repulſion, and then deſcribe the experiments from which thoſe properties have been deduced, or by which they are illuſtrated.

1. The electric fluid, when in action, diſpoſes or places light bodies in ſuch manner as will beſt facilitate its tranſmiſſion through them, with the greateſt velocity; and this in proportion to the gravity of the body, its conducting power, and the ſtate of the air. 2. Bodies that are electrified poſitively repel each other. 3. Bodies electrified negatively repel each other. 4. Bodies electrified by contrary powers attract each other ſtrongly. 5. Bodies that are electrified, attract thoſe ſubſtances which are not electrified. 6. Thoſe ſubſtances that are brought within the influence of electrified bodies, become poſſeſſed of a contrary electricity; or electrified ſubſtances, without parting with their own electricity, act upon other bodies in their neighbourhood, producing in them an electricity which is contrary to their own; or bodies which are immerged in an electric atmoſphere always become poſſeſſed of an electricity contrary to that of the body in whoſe atmoſphere they are immerged.

The experiments deſcribed in this article are ſimple, eaſily performed, and certain in their reſults; and, though they may at firſt ſight appear to be trifling, yet, on an attentive examination, they will be found of conſiderable importance, as they afford a clue to inveſtigate and explain a variety of electric phænomena, and exhibit, in a ſtrong point of view, ſome of the contrary effects of negative and poſitive electricity.

Theſe experiments may all be made with a ſmall and portable apparatus; conſiſting generally of two braſs tubes, each of theſe is ſupported on a glaſs pillar, which ſcrews into a wooden foot; a pair of ſmall pith balls ſuſpended on linen threads, fit upon each tube by means of a ſmall braſs ring; theſe tubes, with a piece of ſealing-wax or a glaſs tube, are ſufficient to illuſtrate the greater part of the experiments in this article, as well as ſome of the principal phænomena in electricity. The apparatus will be rendered more complete, when it conſiſts of four braſs tubes with their ſtands. Mr. Wilſon, in a maſterly tract on this ſubject, entitled, "A ſhort view of Electricity," has, with a ſimilar apparatus, explained and illuſtrated all its general principles.

Electrified Balls.

Experiment 1. Touch a pair of inſulated pith balls with an excited glaſs tube, they will become electrified, and will ſeparate from each other; the balls are electrified poſitively, and are therefore attracted by excited wax, and repelled by excited glaſs.

As thoſe light ſubſtances, which poſſeſs the ſame electric power, repel each other; we can eaſily diſcover whether they are electrified poſitively or negatively, by preſenting an excited ſtick of ſealing-wax or glaſs to them. If they are attracted by the glaſs, they are negatively, if repelled by it they are poſitively electrified; on the contrary, if repelled by the excited wax, they are negative, if attracted, poſitive.

In aſcertaining the nature of the electric powers, we muſt avoid bringing the bodies to be tried near each other ſuddenly; or one with a ſtrong electricity near another which is weakly ſo, as it may render the experiment doubtful by attracting and not repelling the light body.

Hold an excited glaſs tube over a braſs tube, but at ſome diſtance from it, part of the natural quantity of electricity contained in the braſs tube will be driven into the pith balls that are annexed to it, by the excited glaſs, the balls will diverge with poſitive electricity; remove the excited glaſs, the balls will then return to their natural ſtate, and cloſe. If the excited glaſs continues in its place, the balls will continue to be repelled; for the excited electric will always continue to ſeparate the powers of electricity, or in other words to force a quantity from the ſurface of the tube; and will alſo prevent its return, ſo long as it continues of the ſame force, and acts at the ſame diſtance.

The nearer the excited electric is brought, the greater is the effect. The ſphere of action of an excited electric has been diſtinguiſhed into two parts, one termed the *ſphere of influence*, in which the balls will ſeparate, but cloſe when the electric is removed; the other is called the *ſphere of communication*, in this the force acquired by the balls remains after the excited electric is removed.

The electrified Cork-ball Electrometer.

Experiment 2. When the machine is in order, and the prime conductor is ſet ſo that the points of the collector are about half an inch from the ſurface of the cylinder, fix at the end of the prime conductor the knobbed rod Plate I. *fig.* 5. and hang on it the electrometer with the cork-balls. The balls will now touch one another, the threads hanging perpendicularly, and parallel to each other. But if the cylinder of the machine be whirled by turning the winch E, then the cork-balls will repel one another, and more, or leſs, according as the electricity is more or leſs powerful. In this experiment, the glaſs cylinder extracting the electric fluid from the rubber, throws it upon the pointed wires of the collector, and in conſequence upon the prime conductor, and the electrometer; which are all connected together; and as bodies overcharged with electric fluid will always repel each other, ſo the cork-balls muſt repel each other. If the electrometer be hung to a prime conductor negatively electrified, i. e. connected with the inſulated rubber of the machine, the cork-balls will alſo repel each other; for bodies, undercharged, will repel each other, as well as bodies overcharged with electric fluid.

If, in this ſtate of repulſion, the prime conductor is touched with ſome conducting ſubſtance not inſulated, the cork-balls will immediately come together; for the electric fluid ſuperinduced upon the prime conductor, and the electrometer communicating with it, will be carried away to the ground by that conducting

body; ſo that in this caſe the prime conductor can never be overcharged; nor can it be undercharged, if connected with the rubber; for its deficiency of fluid is ſupplied through that conducting body, with which it has been touched. But if, inſtead of the conducting ſubſtance, the prime conductor is touched with an electric, as for inſtance a ſtick of ſealing-wax, a piece of glaſs, &c. then the cork-balls will continue to repel each other; becauſe the electric fluid cannot be conducted through that electric: hence we have an eaſy method of determining what bodies are conductors, and what electrics. This method in groſs will do very well; but when the conducting power of fluids or ſome other bodies, and the degree of that power, is to be aſcertained, then recourſe muſt be had to other means, more nice and accurate.

This electrical repulſion is alſo ſhewn by the quadrant electrometer, with a large downy feather, or the like; for if theſe be connected with the prime conductor, and the winch be turned, the electrometer will raiſe its index, and the feather, by the divergency of its down, will appear ſwelled in a beautiful manner. Excited glaſs held over the middle of the tube, forces ſome part of the natural quantity of electricity into the balls that are ſuſpended, and ſome part out at the two ends into the air. During this experiment, the balls are repelled by glaſs, and are therefore in a poſitive ſtate; but, after the excited glaſs is removed, they in a very little time change to a negative ſtate, becauſe part of the natural quantity had eſcaped from the pointed ends into the air, while the glaſs was held over the tube; but, when the glaſs is removed, the over-charge in the balls will of courſe return, and diffuſe itſelf equally in the tube, but as this is not ſufficient to ballance the loſs ſuſtained, the tube, thread, and balls muſt be in a negative ſtate. It may be inferred from this experiment, that whenever the electric fluid in any body becomes ſuddenly more denſe in any one part, the fluid in the neighbouring parts will be more rare, and vice verſa. Theſe alternate changes of rarity and denſity muſt, from the nature of an elaſtic fluid, continue to oſcillate many times backwards and forwards before the fluid can be at reſt; though, when theſe motions are weakened to a certain degree they are imperceptible to the obſerver. Moſt of the preceding experiments may be had with cylinders of wood or glaſs inſtead of braſs. When glaſs is uſed it muſt be kept dry and not diſturbed by friction. It is not improbable that the attractive and repulſive motions of electrified bodies are owing to the alternate condenſation and dilatation of the electric fluid on the ſurface of theſe bodies, as they are naturally carried where they meet with the leaſt reſiſtance. That there is a vibratory motion, or ſtruggle, between the electric fluid, when in action, and the air, is evident from that ſenſation which is felt when a ſtrongly excited electric is brought near any part of the human body; and is ſuch as would be occaſioned by a ſpider's web drawn lightly along the ſkin. This circumſtance is rendered more clear by an experiment made by Dr. Prieſtley, in order to diſcover whether electricity was concerned in the freezing of water. He placed two diſhes with water in the open air in the time of a ſevere froſt, one of them he kept ſtrongly electrified, and could obſerve no difference in the time when it began to freeze, or in the thickneſs of the ice when it had been frozen ſome time; but he obſerved, on each ſide of the electrified wire, the ſame dancing vapour which is ſeen near the ſurface of the earth in a hot day, or at any time near a body ſtrongly heated.

Strong Attraction and Repulſion between electrified Silk Stockings.

Experiment 3. The following curious obſervations were made by Mr. Symmer. He had been accuſtomed to wear two pair of ſilk ſtockings, a black and a white; when theſe were pulled off both together no ſigns of electricity appeared; but, on pulling off the black ones from the white, he heard a ſnapping or cracking noiſe, and in the dark perceived ſparks between them. To produce this and the following appearances in great perfection, it was only neceſſary to draw his hand ſeveral times backward and forward over his leg with the ſtockings upon it.

When the ſtockings were ſeparated and held at a diſtance from each other, both of them appeared to be highly excited; the white ſtocking poſitively, the black negatively. While they were kept at a diſtance from each other, both of them appeared inflated to ſuch a degree that they exhibited the intire ſhape of the leg. When two black or two white ſtockings are held in one hand, they repel one another with conſiderable force. When a white and a black ſtocking are preſented to each other, they are mutually attracted, and ruſh together, if permitted, with great violence. As they approach, the inflation gradually ſubſides, and their attraction of foreign objects diminiſhes, but their attraction of one another increaſes; when they actually meet, they become flat and joined cloſe together, like ſo many folds of ſilk; when ſeparated again, their electric virtue does not ſeem to be in the leaſt impaired for having once met. The ſame appearances will be exhibited by them for a conſiderable time. When the experiment was made with two black ſtockings in one hand, and two white ones in the other, they were thrown into a ſtrange agitation, owing to the attraction between thoſe of different colours, and the repulſion between thoſe of the ſame colour. This mixture of attractions and repulſions made the ſtockings catch at each other at greater diſtances than otherwiſe they would have done, and afforded a very curious ſpectacle.

When the ſtockings were ſuffered to meet, they ſtuck together with conſiderable force; at firſt Mr. Symmer found they required from one to twelve ounces to ſeparate them. Another time they raiſed 17 ounces. Getting the black ſtockings new dyed, and the white ones waſhed, and whitened in the fumes of new ſulphur, and then putting them one within the other, with the rough ſides together they required three pounds three ounces to ſeparate them. When the white ſtocking was put within the black one, ſo that the outſide of the white was contiguous to the inſide of the black, they raiſed nine pounds, wanting a few ounces; when the two rough ſurfaces were together, they raiſed fifteen pounds, one penny weight and a half. The Rev. Mr. Lyons has made many curious experiments on the attraction of ribbons; their coheſion; &c. See Lyon's Experiments and Obſervations on Electricity.

The Electrical Jack.

Experiment 4. This is an invention of Dr. Franklin's, and turns with conſiderable force, it may be uſed for the purpoſes of a common jack. A ſmall upright ſhaft of wood paſſes at right angles through a thin round board of about 12 inches diameter, and turns on a ſharp point of iron fixed in the lower end, while a ſtrong wire in the upper end, paſſing through a ſmall hole in a thin braſs plate, keeps the ſhaft truly vertical. About 30 radii, of equal length, made of ſaſh-glaſs cut into narrow ſlips, iſſue horizontally from the circumference of the board, the ends moſt diſtant from the centre being about four inches apart. On the end of every one a braſs thimble is fixed If now the wire of a bottle electrified in the common way be brought near the circumference of this wheel, it will attract the neareſt thimble, and ſo put the wheel in motion. That thimble, in paſſing by, receives a ſpark; and thereby being electrified, is repelled, and ſo driven forwards; while a ſecond, being attracted, approaches the wire, receives a ſpark, and is driven after the firſt; and ſo on, till the wheel has gone once round; when the thimbles before electrified approaching the wire, inſtead of being attracted, as they were at firſt, are repelled, and the motion preſently ceaſes. But if another bottle which had been charged through the coating, or otherwiſe negatively electrified, is placed near the ſame wheel, its wire will attract the thimble repelled by the firſt, and thereby double the force that carries the wheel round. The wheel therefore moves very ſwiftly, turning round 12 or 15 times in a minute, and with ſuch force, that a large fowl ſpitted on the upper ſhaft may be roaſted by means of it.

Dancing Figures.

Experiment 5. Suſpend the ſmall metal plate F, *fig.* 5, to the conductor by the hook H; place the ſtand I, directly under it, and the large plate G on the top of the ſtand; the upper part of the ſtand I, is moveable, ſo that the diſtance of the two plates from each other may be occaſionally varied. Lay ſmall paper images, or any other light ſubſtances, on the under plate, then put the machine in action, and the light bodies will be attracted and repelled by each plate, and move from one plate to the other with conſiderable velocity.

The light bodies placed on the under plate become poſſeſſed of an electricity which is contrary to that of the upper plate, and are therefore attracted by it, and acquire the ſame electricity with it; they are then repelled, and part with this electricity to the ſtand, and are again in a proper ſtate to be attracted by the upper plate. That theſe bodies cannot be attracted by the upper plate, till they have acquired a power contrary to it, or till the equilibrium of the fluid in them is diſturbed, will be evident from the following experiment. Remove the under plate and ſtand; hold in its ſtead, by one corner, a pane of glaſs, which has previouſly been made very clean and dry; now, as glaſs does not tranſmit electricity, no contrariety in the electric ſtates of the conductor and the light ſubſtances can be occaſioned, and therefore no attraction or repulſion is obſerved. If a finger is preſented to the under ſide of the glaſs plate, the light bodies will be attracted and repelled: the cauſe of this will be ſeen when the nature of the Leyden phial is explained.

Mr. Eeles, (Philoſophical Eſſays, preface, page 25,) ſpeaking of this alternate attraction and repulſion, ſays, they may be agreeably varied, by wetting firſt the head of the paper images, and when theſe are dry, wetting the feet.

"When you dry the head of one of thoſe images, the power thown out from the conductor, cannot enter the image with the ſame facility with which the contrary power from the table enters at the feet, which are not ſo dry; this will therefore aſcend to the upper plate and remain there. Reverſe the experiment; dry the feet and wet the head, and the images will fix themſelves to the lower plate. If the image retains ſo much more of the attracted power as will ballance againſt its weight, than there is of the contrary power which proceeds from the conductor, the image will be ſuſpended between the two plates.

"This may be effected by making the head of the image broad and round, which does not admit the power coming out ſo readily as the feet, being ſharp, admit the power going in; a minute alteration will make the images dance, or remain fixed to one of the plates. In this experiment the figures will ſometimes move one upon another, or exhibit different poſtures, ſo as to afford a pleaſing ſpectacle to an obſerving company.

The Electrified Bells.

Experiment 6. *Fig.* 21 repreſents a ſmall ſet of bells, which are cauſed to ring by the powers of attraction and repulſion; the two exterior ones are connected to the wire VY, by a braſs chain; the middle bell and the clappers are ſuſpended on ſilk.

Hang the bells on the conductor by the hook RS, let the chain from the middle bell touch the table, turn the cylinder, and the clappers will fly continually from bell to bell, as long as the electricity continues.

The braſs chain, which connects the two exterior bells to the conductor, conveys the electric fluid to them, which attracts the clappers; theſe, when they have received the electric fluid, are repelled by the exterior bell, and attracted by the middle one, on which they depoſit their electricity; they are then again attracted and repelled by the outer bells. Hold up, by a ſilk thread, the chain, which proceeds from the middle bell, and the ringing will ceaſe, becauſe it cannot convey the electric fluid communicated by the clappers to the ground.

Fig. 20 repreſents a more elegant form of mounting the bells. When this is uſed, the knob *a* ſhould communicate with the conductor.

Fig. 19 repreſents another kind. In this the clapper is ſuſpended from the fly *b c d*, the axis of the fly reſts in a ſmall hole on the top of the glaſs pillar *e f*, the upper part of the axis moves freely in, and is ſupported by a hole in the braſs piece *g*. Bells of different tones are placed round the board *h* I K. Remove the prime conductor, and place this apparatus in it's ſtead near the cylinder; when this is in action, it will cauſe the fly to turn round, the clapper will ſtrike each bell in rotation, and thus produce a pleaſing and harmonious ſound.

The Dancing Balls.

Experiment 7. Put a pointed wire into one of the holes which are at the end of the conductor, hold a glaſs tumbler over the point, then electrify the conductor, and turn the tumbler round, that the whole interior ſurface may receive the fluid from the point; place a few pith balls on the table, and cover them with this glaſs tumbler, the balls will immediately begin to leap up and down as if they were animated, and will continue to move for a long time. See *fig.* 4. This experiment may be agreeably varied with two tumblers. Electrify the inſide of one poſitively, of the other negatively; put the balls in one tumbler, and then bring the mouths of both in contact, the balls will paſs from one to the other, till the contrariety between them is deſtroyed.

The flying Feather, or ſhuttle Cock.

Experiment 8. The phenomena of electric attraction and repulſion may be repreſented alſo with a glaſs tube, or a charged bottle, and ſome of them in a manner more ſatisfactory than with the machine. Take a glaſs tube (whether ſmooth, or rough, is not material), and after having rubbed it, let a ſmall light feather be let out of your fingers at a diſtance of about eight or nine inches from it. This feather will be immediately attracted by the tube, and will ſtick very cloſe to its ſurface for about two or three ſeconds, and ſometimes longer; after which time it will be repelled, and if the tube be kept under it, the feather will continue floating in the air at a conſiderable diſtance from the tube, without coming near it again, except it firſt touches ſome conducting ſubſtance; and if you manage the tube dexterouſly, you may drive the feather through the air of a room at your pleaſure. The reaſon of this experiment is obvious; for when the feather is electrified, it cannot approach the tube again, except it firſt touches ſome conducting body, becauſe it cannot part with its electricity when floating in the air, and therefore cannot acquire a contrary electricity: conſequently it muſt remain in a ſtate incapable of being again attracted by the excited tube. If it be aſked, why, when the feather is at firſt attracted by the tube, it ſticks for ſo conſiderable a time to its ſurface before it is repelled? the anſwer is, that the feather being an electric, requireth ſome time before it acquires any conſiderable quantity of electricity.

There is a remarkable circumſtance attending this experiment, which is, that if the feather be kept at a diſtance from the tube by the force of electric repulſion, it always preſents the ſame part towards the tube: you may move the excited tube about the feather very ſwiftly, and yet the ſame ſide of the feather will always be preſented to the tube. The reaſon of this phenomenon is, that equilibrium of the electric fluid in the parts of the feather, being once diſturbed, cannot eaſily be reſtored; becauſe the feather is an electric, or at leaſt a very bad conductor. When the feather has acquired a quantity of electricity from the tube, it is plain, that by the action of the excited tube, that ſuperinduced electricity will be in the greateſt part forced on that ſide of the feather which happens to be at firſt the fartheſt from the tube; hence that part will always afterward be repelled the fartheſt. This experiment may be agreeably varied in the following manner: A perſon may hold in his hand an excited tube of ſmooth glaſs, and another perſon may hold an excited rough glaſs tube, a ſtick of ſealing-wax, or in ſhort another electric negatively electrified, at about one foot and a half diſtance from the ſmooth glaſs tube: a feather now may be let go between theſe two differently excited electrics, and it will leap alternately from one electric to the other; and the two perſons will ſeem to drive a ſhuttle-cock from one to the other, by the force of electricity.

To diſtinguiſh the Quality of Electricity in electrified Bodies.

Experiment 9. Before we proceed further, it is neceſſary that we ſhould deſcribe ſome practical method of diſtinguiſhing the quality of the electricity in an electrified body, which is abſolutely neceſſary for the right performance of the enſuing experiments. To do this, different methods may be followed, which however are all founded, either upon the electric attraction, and repulſion, or upon the different appearances of the electric light. To find out the quality of electricity by the different appearances of its light, is a very convenient, and ſure method; but the phenomena of attraction and repulſion, afford one much more general, and eaſy; for ſometimes the quantity of electricity to be obſerved is ſo very ſmall, that it will give no light, though it may be ſtill capable of attracting or repelling. The general method to prove whether the electricity of a body, electrified either by excitation, or communication, is negative, or poſitive, is to bring it pretty near to an electrified electrometer D or C, *fig.* 36, and obſerve whether the body attracts or repels it; for if the electrometer is electrified poſitively, and the electrified body repels it, then you may conclude that the body is alſo electrified poſitively; becauſe bodies, poſſeſſed of the ſame kind of electricity, repel each other; but if the body preſented attracts the electrometer, then it muſt be electrified negatively, becauſe there is no electric attraction between bodies, unleſs they are differently electrified; and as the electrometer is known to be electrified poſitively, the body is conſequently electrified negatively.

The following preciſe method may lead to determine the quality of the electricity of an electrified body.

Firſt, electrify one of the electrometers C, *fig.* 36, either poſitively, or negatively, at pleaſure: touch it, for inſtance, with an excited glaſs tube, ſo that its balls may repel, and ſtand about two inches diſtant from one another; then touch the other electrometer C with the electrified body, that you deſire to examine, ſo that it may be poſſeſſed of the ſame degree of electricity: laſtly, take either of the two electrometers by the top of the glaſs handle *a*, diſengage it from the arm of the ſtand, and bring it near the other electrometer; if then the balls of one electrometer repel thoſe of the other, you may conclude that they are poſſeſſed of the ſame kind of electricity; but if they attract each other, you may conclude that they were electrified with contrary electricities; and as you know the electricity of that electrometer, which was firſt electrified, you will alſo know the electricity of the other electrometer, i. e. of the electrified body, with which it was touched.

The above experiment may be alſo made with the ſingle-thread electrometers; ſuch as are ſuſpended at the end of *fig.* 30. for if they are brought near to one another, when their feathers are electrified, they will, if poſſeſſed of the ſame electricity, repel, or if poſſeſſed of contrary electricities, attract each other. To account for any of the phænomena of electric attraction and repulſion, is very difficult, but more ſo to ſhew why bodies, which are electrified with the ſame power, repel each other, particularly thoſe which are negatively electrified. Philoſophers have invented various ſolutions of this difficulty; Cavallo's, which he has introduced in his treatiſe Part 110, is eſteemed the beſt.

From ſeveral experiments of Beccaria's, it appears, that, if the air is thoroughly exhauſted from a glaſs receiver, the attraction and repulſion of electrified light bodies within the receiver grow languid, and ſoon ceaſe altogether. This is confined by an experiment of Mr. Cavallo's. A pith ball electrometer was ſuſpended within a receiver of an air pump, by it's braſs cap; this was then electrified; the balls diverged a little when the air was only rarified 100 times: when it was rarified 300 times, the repulſion was ſcarce diſcernable; when the rarifaction was greater, they did not diverge at all; and that, whether a ſmall or large quantity of electricity was communicated to the cap. Phil. Tranſ. vol. 73, p. 452.

ARTICLE II.

EXPERIMENTS ON ELECTRIC LIGHT.

The following experiments require to be made in the dark; for although the electric light, in ſeveral circumſtances, may be ſeen in the day light, yet its appearance in this manner is very confuſed; and, that the electrician might form a better idea of its different appearances, it is abſolutely neceſſary to perform ſuch experiments in a darkened room.

The Star and Pencil of electric Light.

Experiment 1. When the electrical machine is in good order, and the prime conductor is ſituated with the collector ſufficiently near the glaſs cylinder (which ſituation we ſhall call hereafter its proper place) turn the winch, and you will ſee a lucid ſtar at each of the points of the collector. This ſtar is the conſtant appearance of the electric fluid that is entering a point. At the ſame time, you will ſee a ſtrong light proceeding from the rubber, and ſpreading itſelf over the ſurface of the cylinder; and, if the excitation of the cylinder is very powerful, denſe ſtreams of fire will proceed from the rubber, and, darting round almoſt half the circumference of the cylinder, will reach the points of the collector. If the prime conductor is removed, the denſe ſtreams of fire will go quite round the cylinder; reaching from one ſide of the rubber to the other. By obſerving on which ſide of the cylinder thoſe ſtreams are moſt copious, it may be eaſily determined which ſide of the rubber preſſes more or leſs upon the cylinder, or is better covered with amalgam, or, in ſhort, which ſide is the moſt or leaſt fit for the excitation of the glaſs. If the chain of the rubber is taken off, and a pointed body (as for inſtance, the point of a needle or a pin) is preſented to the back of the rubber, at the diſtance of about two inches, a lucid pencil of rays will appear to proceed from the point preſented, and diverge towards the rubber. This pencil is the conſtant appearance of the electric fluid iſſuing from a point; and in fact, it now comes out of the point, in order to ſupply the rubber, which is conſtantly exhauſted by the cylinder in motion. If another pointed body be preſented to the prime conductor, it will appear illuminated with a ſtar; but if a pointed wire, or other pointed conducting body, be connected with the prime conductor, it will throw out a pencil of rays; for, the prime conductor being overcharged, the fluid departing from it muſt, agreeably to the law, form a pencil on that point from which it flies off, and a ſtar on that point which it enters.

Imitations of the Planetary Motions.

EXPERIMENT 2. From the prime conductor ſuſpend ſix concentric hoops of metal, at diſtances from each other; under them, on a ſtand, place a metal plate at the diſtance of about half an inch. Then place upon the plate within each hoop, and near to it, a round glaſs bubble blown very light; theſe bubbles and the diſtances between the hoops ſhould correſpond to the different diameters of the planets and thoſe of their orbits; but as that cannot be on account of the vaſt diſproportion between them, it muſt ſuffice here to make a difference that bears ſome relation to them. Now, the hoops being electrified, the bubbles placed upon the plate, near the hoops, will be immediately attracted by them, and they will continue to move round the hoops as long as the electrification continues. If the electricity is very ſtrong, the bubbles will frequently be driven off from the hoops, and make a variety of ſurpriſing motions round their axis, and running hither and thither on the plate, after which they will come back to the hoops, and run round them as before. If the room is darkened, all the glaſs balls will appear beautifully illuminated.

To illuminate Wood.

EXPERIMENT 3. Take a ſpark through a ball of box-wood, and it will appear of a beautiful crimſon, or rather a fine ſcarlet colour; or the ſhock may be paſſed through pieces of wood of different thickneſſes and denſity, which will afford a very ample field for obſervation and experiment.

The illuminated ſpiral Tube.

EXPERIMENT 4. E F, *fig.* 2, is a glaſs tube, round which, at ſmall but equal diſtances from each other, pieces of tin foil are paſted in a ſpiral form, (hence it is called the ſpiral tube) from end to end; this tube is incloſed in a larger one, fitted with braſs caps at each end, which are connected with the tin-foil of the inner tube. Hold one end in the hand, and apply the other near enough to the prime conductor to take ſparks from it, a beautiful and lucid ſpot will then be ſeen at each ſeparation of the tin-foil; theſe multiply, as it were, the ſpark taken from the conductor; for if there was no break in the tin-foil, the electric fire would paſs off unperceived.

Fig. 3. repreſents ſeveral ſpiral tubes, placed round a board; a glaſs pillar is fixed to the board, and on this pillar is cemented a metal cap, carrying a ſmall ſteel point; a braſs wire, furniſhed with a ball at each end, and nicely ballanced, is placed on this point; place the middle of this wire under a ball proceeding from the conductor, ſo that it may receive a continued ſpark from the ball, then give the wire a rotative motion, and the balls in revolving will give a ſpark to each ball of the ſpiral tube, which will be communicated from thence to the board; forming, from the brilliancy of the light and its rapid motion, a very pleaſing experiment. All theſe experiments on the interrupted ſpark may be pleaſingly and beautifully varied, and the ſpark made to appear of different colours, at the pleaſure of the operator.

The luminous Word.

EXPERIMENT 5. This experiment is exactly on the ſame principles as the foregoing. The word is formed by the ſmall ſeparations made in the tin-foil, which is paſted on a piece of glaſs that is fixed in a frame of baked wood, as repreſented in *fig.* 1. To make the experiment, hold the frame in the hand, and preſent the ball G to the conductor, the ſpark received on this will be communicated to the tin-foil, and follow it in all its windings, till it arrives at the hook *h*, and is conveyed from thence to the ground by a chain: the lucid appearance at each break exhibits a word in characters of fire.

To illuminate a Decanter of Water.

EXPERIMENT 6. Connect one end of a chain with the outſide of a charged jar, let the other end lie on the table, place the end of another piece of chain at about one quarter of an inch diſtance from the former, then ſet a decanter of water on theſe ſeparated ends, and, on making the diſcharge through the chain, the water will appear perfectly and beautifully luminous.

Do not theſe experiments indicate, that there is a ſubtle medium both in electric and non-electric bodies, that renders them tranſparent, when it is put in motion?

Drawing Sparks.

EXPERIMENT 7. Let the prime conductor be ſituated in its proper place, and electrify it by working the machine; then bring a metallic rod with a round knob at each end, or the knuckle of a finger, within a proper diſtance of the prime conductor, and a ſpark will be ſeen between that and the knuckle, or knobbed wire. The longer and ſtronger ſpark is drawn from that end of the prime conductor which is fartheſt from the cylinder, or rather from the end of the knobbed rod, fixed at its end, *fig.* 5, Plate I.

The reaſon of this is, becauſe that end of the prime conductor is leſs influenced by the atmoſphere of the excited cylinder.

This park (which has the ſame appearance, whether drawn from a prime conductor poſitively, or negatively electrified) appears like a long line of fire; it often darts bruſhes of light ſideways, in every direction, reaching from the conductor to the oppoſed body; and often (particularly when the ſpark is long, and different conducting ſubſtances are near the line of its direction) it will have the appearance of being bended to ſharp angles in different places, exactly reſembling a flaſh of lightning. Notwithſtanding, however, this extended appearance, which is imputed to the quick paſſage of the luminous matter, the electric fluid paſſing from one body to another in a ſpark, is reaſonably thought to proceed in a ſeparate, and nearly globular body.

The direction of the ſpark often deceives the moſt experienced electrician, it ſeeming ſometimes to proceed from one place, and at other times, under the ſame circumſtances, to proceed from the oppoſite. When the prime conductor is electrified poſitively, the ſpark muſt certainly proceed from it, and go to the body preſented; and when the prime conductor is electrified negatively, the ſpark muſt proceed from the body preſented, and go to the conductor. This, however, we learn by reaſoning from other experiments; for the real direction of the ſpark in the above experiment, is much more rapid in its motion than to admit its form, much leſs its direction, to be perceived by our eyes.

The electric Light flaſhing between two metallic Plates.

EXPERIMENT 8. Let two perſons, one ſtanding upon an inſulated ſtool, and communicating with the prime conductor, and another ſtanding upon the floor, each hold in one of his hands a metal plate, in ſuch a manner, that the plates may ſtand back to back in a parallel ſituation, and about two inches aſunder. Let the winch of the machine be turned, and you will ſee the flaſhes of light between the two plates ſo denſe and frequent, that you may eaſily diſtinguiſh any thing in the room. By this experiment, the electric light is exhibited in a very copious and beautiful manner, and it bears a ſtriking reſemblance to lightning.

To fire inflammable Spirits.

EXPERIMENT 9. The power of the electric ſpark to ſet fire to inflammable ſpirits, may be exhibited by ſeveral different methods; but more eaſily thus: hang to the prime conductor a ſhort rod, having a ſmall knob at its end, then pour ſome ſpirit of wine, a little warmed, into a metal ſpoon; hold the ſpoon by the handle, and place it in ſuch manner, that the ſmall knob on the rod may be about one inch above the ſurface of the ſpirit. In this ſituation, if, by turning the winch, a ſpark be made to come from the knob, it will ſet the ſpirit on fire. This experiment happens in the very ſame, whether the conductor is electrified poſitively or negatively, i. e. whether the ſpark be made to come from the conductor, or from the ſpoon; it being only in conſequence of the rapid motion of the ſpark that the ſpirits are kindled. It will be perhaps ſcarce neceſſary to remark, that the more inflammable the ſpirits are, the more proper they will be for this experiment, as a ſmaller ſpark will be ſufficient to inflame them; therefore rectified ſpirit of wine is better than common proof ſpirit, and æther better than either.

This experiment may be varied different ways, and may be rendered very agreeable to a company of ſpectators. A perſon, for inſtance, ſtanding upon an electric ſtool, and communicating with the prime conductor, may hold the ſpoon with the ſpirits in his hand, and another perſon, ſtanding upon the floor, may ſet the ſpirits on fire, by bringing his finger within a ſmall diſtance of it. Inſtead of his finger, he may fire the ſpirits with a piece of ice; when the experiment will ſeem much more ſurprizing. If the ſpoon is held by the perſon ſtanding upon the floor, and the inſulated perſon brings ſome conducting ſubſtance over the ſurface of the ſpirit, the experiment ſucceeds as well.

Let an electrified perſon, ſtanding on an inſulated ſtool, hold the ſpirits. Let another perſon, ſtanding alſo on an inſulated ſtool, hold in his hand an iron poker, one end of which is made red hot, he may then apply the hot end to the ſpirits, and even immerge it in them without firing them. But if he put one foot on the floor, he may ſet the ſpirits on fire with either end. The ſpirits cannot be kindled by the inſulated perſon, becauſe, as the electric cannot eſcape through him to the earth, he is incapable of drawing a ſpark ſufficiently ſtrong to inflame them, and hot iron will ſeldom or ever ſet ſpirits on fire. If oil of turpentine is ſet on fire in a veſſel which is placed on the conductor, and the ſmoak is received on a plate, held by a perſon ſtanding on an inſulated ſtool, he will be electrified thereby, and enabled to fire ſpirits of wine, &c. If the inſulated perſon holds a braſs wire at the top of the flame of burning ſpirits of wine, which is connected with the conductor, he will alſo become electrified. Hence we find, that either ſmoke or flame conducts the electrical fluid.

“ Mr. Winckler ſays, that oil, pitch, and ſealing-wax, might be lighted by electric ſparks, provided thoſe ſubſtances were firſt heated to a degree next to kindling. To theſe it muſt be added, that Mr. Gralath fired the ſmoke of a candle juſt blown out, and lighted it again; and that Mr. Boze fired gunpowder, melting it in a ſpoon, and firſt the vapour that roſe from it.”

The artificial Bolonian Stone illuminated by the Electric Light.

EXPERIMENT 10. The moſt curious experiment to ſhew the penetrability of the electric light, is made with the real, or with the artificial Bolonian ſtone, which is procured more eaſily, and was invented by the late Mr. J. Canton. This phoſphorus is a calcareous ſubſtance, generally uſed in the form of a powder, which has the property of appearing lucid, when brought into the dark after having been expoſed to the light. The method of making this phoſphorus is as follows: “ Calcine ſome common oyſter-ſhells” (if they are old, and half calcined by time, ſuch as are commonly found upon the ſea-ſhore, they are, as Mr. W. Canton obſerves, ſo much the better) “ by keeping them in a good coal-fire for half an hour; let the pureſt part of the calx be pulverized, and ſifted; mix with three parts of this powder one part of the flowers of ſulphur; let this mixture be rammed into a crucible of about an inch and a half in depth, till it be almoſt full; and let it be placed in the middle of the fire, where it muſt be kept red-hot for one hour at leaſt, and then ſet it by to cool; when cold, turn it out of the crucible, and cutting or breaking it to pieces, ſcrape off, upon trial, the brighteſt parts; which, if good phoſphorus, will be a white powder, and may be preſerved by keeping it in a dry phial with a ground ſtopple.” If this phoſphorus, whether in the phial or not, be kept in the dark, it will give no light, but if expoſed to the light, either of the day, or of any thing elſe, and afterwards brought into a dark place, it will then appear lucid for a conſiderable time. For farther properties of this phoſphorus, ſee the Phil. Tranſ. Vol. 58.

Take ſome of this powder, and, by means of ſpirit of wine, or æther, ſtick it all over the inſide of a clear glaſs phial, and ſtop it with a glaſs ſtopper, or a cork and ſealing-wax. If this phial be kept in a darkened room (which for this experiment muſt be very dark) it will give no light: but let two or three ſtrong ſparks be drawn from the prime conductor, when the phial is kept at about two inches diſtance from the ſparks, ſo that it may be expoſed to that light, and this phial will receive that light, and afterwards will appear illuminated for a conſiderable time.

This powder may be ſtruck upon a board by the means of the white of an egg, ſo as to repreſent figures of planets, letters, or any thing elſe, at the pleaſure of the operator, and theſe figures may be illuminated in the dark, in the ſame manner as the above-deſcribed phial. A beautiful method to expreſs geometrical figures with the above phoſphorus, is to bend ſmall glaſs tubes, of about the tenth part of an inch diameter, in the ſhape of the figure deſired, and then to fill them with the phoſphorus-powder. Theſe may be illuminated in the manner deſcribed, and they are not ſo ſubject to be ſpoiled, as the figures repreſented upon the board frequently are. The beſt method of illuminating this phoſphorus, and was that Mr. W. Canton generally uſed, is to diſcharge a ſmall electric jar near it. Paper, after being made dry and rather hot, marble, oyſter ſhells, and the moſt calcareous ſubſtances, eſpecially when burned to lime, have the property of being illuminated by the light given by the diſcharge of a jar, though not ſo much as the above-mentioned phoſphorus.

Take ſome of the powder of Canton's phoſphorus, and by means of a little ſpirit of wine, ſtick it all over the inſide of a clean glaſs phial, then ſtop the bottle, and keep it from the light. To illuminate this phoſphorus, draw ſeveral ſtrong ſparks from the conductor, keeping the phial about two or three inches from the ſparks, ſo that it may be expoſed to their light; the phial will afterwards appear luminous, and remain ſo for a conſiderable time.

A curious Method of ſhewing the Penetrability of electric Light.

EXPERIMENT 11. Let the extremities of two wires, one of which proceeds from the outſide of a charged jar, and another from one branch of the diſcharging rod, be laid on a table at about one tenth part of an inch diſtance of each other; then put the thumb juſt upon that interruption, preſſing it flat down. This done, bring the diſcharged rod in contact with the knob of the jar, and on making the diſcharge, the ſpark which neceſſarily happens under the thumb will illuminate it in ſuch a manner, that the bone, and the principal blood veſſels, may be eaſily diſcovered in it. In this experiment the operator needs not be afraid of receiving a ſhock; for the diſcharge of the jar paſſes from wire to wire, and only affects the thumb with a ſort of tremor, which is far from being painful.

The electrified Capillary Syphon.

EXPERIMENT 12. Let a ſmall bucket of metal, full of water, be ſuſpended from the prime conductor, and put in it a glaſs ſyphon of ſo narrow an extremity, as the water will juſt drop from it. If in this diſpoſition of the apparatus the winch of the machine be turned, the water, which, when not electrified, only dropt from the extremity of the ſyphon, will now run in a full ſtream, which will even be ſubdivided into other ſmaller ſtreams; and if the experiment be made in the dark, it will appear beautifully illuminated.

The Aurora Borealis.

EXPERIMENT 13. Take a phial nearly of the ſhape and ſize of a Florence flaſk; fix a ſtop-cock or a valve to its neck, and exhauſt it of air as much as poſſible with a good air-pump. If this glaſs is rubbed in the common manner uſed to excite electrics, it will appear luminous within, being full of a flaſhing light, which plainly reſembles the aurora borealis, or northern light. This phial may alſo be made luminous by holding it by either end, and bringing the other end to the prime conductor; in this caſe all the cavity of the glaſs will inſtantly appear full of flaſhing light, which remains in it for a conſiderable time after it has been removed from the prime conductor. Inſtead of the above-deſcribed glaſs veſſel, a glaſs tube, exhauſted of air and hermetically ſealed, may be uſed, and perhaps with better advantage. The moſt remarkable circumſtance of this experiment is, that if the phial or tube, after it has been removed from the prime conductor (and even ſeveral hours after its flaſhing light hath ceaſed to appear) be graſped with the hand, ſtrong flaſhes of light will immediately appear within the glaſs, which often reach from one of its ends to the other.

ARTICLE III.

EXPERIMENTS ON THE LEYDEN PHIAL.

The experiments upon the Leyden phial are ſome of the moſt intereſting in electricity: they excited the attention of the philoſopher to this ſubject more than any other experiment, and are ſtill viewed with wonder and ſurprize. The phænomena attending this very extraordinary experiment ſeemed totally inexplicable, till they were elucidated by the ingenious theory of Dr. Franklin; which, in a plain and clear manner, accounts for moſt of the difficulties which attend this intricate branch of electricity; and accommodates itſelf ſo eaſily and ſatisfactorily to a variety of appearances, as to make us almoſt loſe ſight of the objections againſt it.

Charging and diſcharging the Leyden Phial.

EXPERIMENT 1. Place the braſs ball of a coated jar in contact with the prime conductor while the outſide communicates with the table, turn the cylinder, and the bottle will in a little time be charged, or modify the electric fluid in a peculiar manner. To diſcharge the jar, or reſtore it to its natural ſtate, bring one end of a conducting ſubſtance in contact with the outſide coating, and let the other be brought near the knob of the jar which communicates with the inſide coating, a ſtrong exploſion will take place, the electric light will be viſible, and the report very loud. Charge the Leyden bottle, then touch the outſide coating with one hand, and the knob with the other, the bottle will be diſcharged, and a ſudden peculiar ſenſation will be perceived, that is called the electric ſhock. The ſhock, when it is taken in this manner, generally affects the wriſts, elbows, and breaſt; when the ſhock is ſtrong, it reſembles an univerſal blow. This peculiar ſenſation is probably owing to the two-fold and inſtantaneous action of the electric fluid, which enters and goes out of the body, and the various parts through which it paſſes, at one and the ſame inſtant. It has been alſo obſerved, that nature has appointed a certain modification of the electric fluid in all terreſtrial bodies, which we violate in our experiments: when this violation is ſmall, the powers of nature operate in a gentle manner to rectify the diſorder we have introduced; but when the deviation is conſiderable, the natural powers reſtore the original conſtitution with extreme violence.

If ſeveral perſons join hands, and the firſt touches the outſide of a charged jar, and the laſt the knob, the bottle will be diſcharged, and they will all feel the ſhock at the ſame inſtant; but the greater the number of perſons that join hands to take a ſhock, the weaker it is. The force of the ſhock is in proportion to the quantity of coated ſurfaces, the thinneſs of the glaſs, and the power of the machine; or, the effect of the Leyden phial is increaſed, in proportion as we deſtroy the equilibrium on the ſurfaces. A given quantity of electricity, impelled through our body with a given force, produces a weaker ſenſation than twice that quantity impelled with half that force, and conſequently the ſtrength of the ſhock depends rather more on the quantity of fluid, which paſſes through our body, than on the force with which it is impelled. Yet the force of an exploſion ſeems to depend more on the degree to which the fluid is compreſſed, than on the quantity; hence a ſmall phial fully charged, will act nearly as ſtrong as a larger jar which is half charged.

If a charged jar is coated very high, it will diſcharge itſelf before it has received near the charge it would take if the coating was lower. If it is coated very low, this part of the ſurface may be charged very high, but a conſiderable part of the glaſs is not charged at all. When a jar is charged very high, it will often explode or diſcharge itſelf over the glaſs from one coated ſurface to the other; or, if the glaſs is thin, it will make a hole through it, and ſwell the coating on both ſides, the glaſs in the hole will be pulverized, and very often a variety of fiſſures will proceed from it in various directions. A Leyden jar very often recovers its electricity, in a ſmall degree, after a diſcharge has been made; this ſecond exploſion is called the reſiduum of a charge.

To avoid receiving the electric ſhock, be careful never to touch the top and bottom of the jar at the ſame time, and never to enter a circuit formed between the inſide and outſide of a jar; for the effect of the Leyden phial depends entirely on the reciprocal action of the two ſurfaces, and does not take place, when either is touched ſeparately. By attending to this obſervation, jars of any ſize may be handled with ſafety. Indeed, the human frame makes ſo little reſiſtance to the free paſſage of this ſubtle agent, that no other inconvenience will attend a ſhock from a common ſized charged jar, than a tranſient diſagreeable ſenſation.

Touch the knob of a charged jar, no ſhock will enſue; but the finger, or part that touches the ball of the jar, will be affected with a ſharp ſenſation, as if it had been pricked with a needle. The diſcharge is ſilent and without an exploſion, when the communication between the two ſides of the jar is made by imperfect conductors. A charged phial ſet upon electric ſubſtances, may be taken hold of without danger, either by the coating or the wire; a ſmall ſpark only will proceed from either.

Combined Apparatus.

The apparatus repreſented *fig.* 22, will be found exceedingly convenient for making a variety of experiments on the Leyden phial. We have endeavoured to combine the parts of it in ſuch manner, as to render the apparatus extenſively uſeful, without being complicated. A is an inſulated pillar of glaſs, which is ſcrewed to the wooden foot B: all the different parts of the apparatus may be ſcrewed alternately on this pillar. C is an exhauſted tube of glaſs, furniſhed at each end with braſs caps: at the end D is a valve, properly ſecured under the braſs plate; a braſs wire, with a ball, projects from the upper cap; a pointed wire proceeds from the bottom plate; this tube is called the luminous conductor. The flaſk, repreſented at E, is called the Leyden vacuum. It is furniſhed with a valve under the ball E; this ball unſcrews, in order to come more readily at the valve; a wire, with a blunt end, projects a little below the neck of the flaſk; the bottom of the flaſk is coated with tin foil: a female ſcrew is cemented to the bottom, in order to ſcrew it on the pillar A.

F is a ſyringe to exhauſt the air occaſionally, either from the luminous conductor, or the Leyden vacuum. To do this, unſcrew the ball of the Leyden vacuum, or the plate of the luminous conductor, and then ſcrew the ſyringe in the place of either of theſe pieces, being careful that the bottom of the female ſcrew G bears cloſe againſt the leather which covers the ſhoulders *a b*, and *c d*, then work the ſyringe, and in a few minutes the glaſſes will be ſufficiently exhauſted. H and I are two Leyden bottles, each of which has a female ſcrew fitted to the bottom, in order that they may be conveniently ſcrewed on the pillar A. The bottle H is furniſhed with a belt, that it may be ſcrewed ſideways on the pillar A. K and L are two ſmall wires, which are to ſcrew occaſionally into either the ball E, the knobs *e* or *f*, the cap *c*, or the ſocket *g*, on the top of the pillar: the balls may be unſcrewed from theſe wires, which will then exhibit a blunt point. M is a wooden table to be ſcrewed on the glaſs pillar occaſionally.

The Leyden Vacuum.

Experiment 2. *Fig.* 22. of Plate 2. repreſents a ſmall phial E, *b a*, coated on the outſide about three inches up the ſides with tin-foil; at the top of the neck of this phial, a braſs cap is cemented, having a hole with a valve, and from the cap a wire proceeds a few inches within the phial, terminating in a blunt point. When this phial is exhauſted of air, a braſs ball is ſcrewed upon the braſs cap, ſo as to defend the valve, and prevent any air from getting into the exhauſted glaſs. This phial exhibits clearly the direction of the electric fluid, both in charging and diſcharging; for if it be held by its bottom, and its braſs knob be preſented to the prime conductor poſitively electrified, you will ſee that the electric fluid cauſeth the pencil of rays to proceed from the wire within the phial, and if its diſcharged, a ſtar will appear in the place of the pencil. But if the phial is held by the braſs cap, and its bottom be touched with the prime conductor, then the point of the wire, on its inſide, will appear illuminated with a ſtar when charging, and with a pencil when diſcharging. If it be preſented to a prime conductor electrified negatively, all theſe appearances, both in charging and diſcharging, will be reverſed. The ſame experiment is beautifully diverſified by means of the luminous conductor, C D, *fig* 22.

The courſe of the Electric Fluid in the Diſcharger rendered viſible by the Star and Pencil.

Experiment 3. *Fig.* 15, is an electric jar, B B the tin-foil coating, C a ſtand which ſupports the jar, D a ſocket of metal which carries the glaſs rod E; a curved metallic wire, pointed at each end, is fixed to the end of the rod G, which rod is moveable at pleaſure in a ſpring tube N, that tube being fixed by a ſocket upon the top of the glaſs rod E, the charging wire communicates with the different diviſions of the inſide coating of the jar by horizontal wires. Place the jar as uſual, and put the machine in action, a ſmall luminous ſpark will appear upon the upper point of the wire F, (a plain indication that the point is then receiving electricity from the upper ring of the coating on the outſide of the jar) a fine ſtream or pencil of rays will at the ſame time fly off, beautifully diverging from the lower point of the wire E upon the bottom ring of the coating on the jar; when theſe appearances ceaſe, which they will as ſoon as the jar is charged, let a pointed wire be preſented towards the prime conductor, this will ſoon diſcharge the jar ſilently, during which, the lower point will be illuminated with a ſmall ſpark, while the upper point of the wire will throw off a pencil of rays, diverging towards the upper ring of the coating.

The Magic Picture.

Experiment 4. This is a contrivance of Mr. Kinnerſley; and more calculated to give ſurpriſe, than any other experiment. It is made in the following manner: having a large mezzotinto, with a frame and glaſs, (ſuppoſe of the king), take out the print, and cut a pannel out of it near two inches diſtant from the frame all round. If the cut be through the picture, it is nothing the worſe. With thin paſte, or gum water, fix the board that is cut off on the inſide of the glaſs, preſſing it ſmooth and cloſe; then fill up the vacancy, by gilding the braſs well with leaf gold or braſs. Gild likewiſe the inner edge of the back of the frame all round, except the top part, and form a communication between that gilding and the gilding behind the glaſs; then put in the board, and that ſide is finiſhed. Turn up the glaſs, and gild the foreſide exactly over the back gilding; and when it is dry, cover it, by paſting on the pannel of the picture that has been cut out; obſerving to bring the correſpondent parts of the board and picture together, by which the picture will appear of a piece as at firſt; only part is behind the glaſs, and part before. Laſtly, hold the picture horizontally by the top, and place a little moveable gilt crown on the king's head. If now the picture is moderately electrified, and another perſon take hold of the frame with one hand, ſo that his fingers touch its inſide gilding, and with the other endeavour to take off the crown, he will receive a terrible blow, and fail in the attempt. The operator, who holds the picture by the upper end, where the inſide of the frame is not gilt, to prevent its falling, feels nothing of the ſhock; and may touch the face of the picture without danger, which he pretends to be a teſt of his loyalty.

Imitation of Rain and Snow.

Experiment 5. Put a quantity of braſs duſt into a coated jar, and when it is charged invert it, and throw ſome of the duſt out, which will be ſpread in an equable and uniform manner on any flat ſurface, and fall juſt like rain or ſnow. May it not be queſtioned, ſays an ingenious writer, whether water, falling from the higheſt region of the clouded atmoſphere, would not meet the earth in much larger drops, or in cataracts, if the coaleſcing power of the drops was not counteracted by their electric atmoſpheres.

Illuminated Jar.

Experiment 6. TV. *Fig.* 10 repreſents a bottle, whoſe exterior coating is formed of ſmall pieces of tin-foil, placed at a little diſtance from each other. Charge this bottle in the uſual manner, and ſtrong ſparks of electricity will paſs from one ſpot of tin-foil to the other, in a variety of directions; the ſeparation of the tin-foil making the paſſage of the fluid from the outſide to the table viſible. Diſcharge this bottle, by bringing a pointed wire gradually near the knob, and the uncoated part of the glaſs between the ſpots will be pleaſingly illuminated, and the noiſe will reſemble that of ſmall fired crackers. If the jar is diſcharged ſuddenly, the whole outſide ſurface appears illuminated. To produce theſe appearances, the glaſs muſt be very dry.

Diſcharges of the double Jar.

Experiment 7. *Fig.* 13 repreſents two Leyden phials, placed one over the other. Various experiments may be made with this double bottle, which are very pleaſing, and elucidate clearly the received theory. Bring the outſide coating of the bottle A in contact with the prime conductor, and turn the machine till the bottle is charged, then place one ball of the diſcharging rod upon the coating of B, and with the other touch the knob of the jar A, which will cauſe an exploſion. Now place one ball of the diſcharger on the knob of A, and bring the other ball to its coating, and you have a ſecond diſcharge. Again, apply one ball of the diſcharger on the coating of B, and carry the other to the coating of A, and it will produce a third exploſion. A fourth is obtained by applying the diſcharger from the coating of A to its knob. The outer coating of the upper jar communicating with the inſide of the under one, conveys the fluid from the conductor to the large jar, which is therefore charged poſitively; the upper jar does not charge, becauſe the inſide cannot part with any of it's electric fluid: but when a communication is formed from the outſide of A to the inſide of B, part of the fire on the inſide of A will be conveyed to the negative coating of B, and the jar will be diſcharged. The ſecond exploſion is occaſioned by the diſcharge of the jar A: but as the outſide of this communicates, by conducting ſubſtances, with the poſitive inſide of the jar B, if the ball of the diſcharging rod remains a ſmall time after the diſcharge on the knob of A, part of the fire of the inſide of A will eſcape, and be replaced by an equal quantity on the outſide from the jar B, by which means A is charged a ſecond time; the diſcharge of this produces the third, and of B the fourth exploſion.

To make the electric Spark viſible in Water.

EXPERIMENT 8. Fill a glaſs tube, of about half an inch diameter, and ſix inches long, with water, and to each extremity of the tube adapt a cork, which may confine the water; through each cork inſert a blunt wire, ſo that the extremities of the wires within the tube may be very near one another; laſtly, connect one of theſe wires with the coating of a ſmall charged phial, and touch the other wire with the knob of it; by which means the ſhock will paſs through the wires, and cauſe a vivid ſpark to appear between their extremities within the tube. In performing this experiment care muſt be taken, that the charge be exceedingly weak, otherwiſe the tube will burſt.

To fire Gun-powder.

EXPERIMENT 9. Make a ſmall cartridge of paper, and fill it with gun-powder, or elſe fill the tube of a quill with it; inſert two wires, one at each extremity, ſo that their ends within the quill, or cartridge, may be about one fifth of an inch from one another; this done, ſend the charge of a phial through the wires, and the ſpark between their extremities, that are within the cartridge, or quill, will ſet fire to the gun-powder. If the gun-powder be mixed with ſteel filings, it will take fire more readily, and with a ſmall ſhock.

To light a Candle by the Diſcharge of a Jar.

EXPERIMENT 10. Take a wire of the ſize of a common knitting-needle, and by means of a ſmall flexible wire or a chain, let one end of it communicate with the outſide of a jar, that at leaſt contains about ten inches of coated ſurface. To the other end of the thick wire ſome cotton muſt be twiſted, but very looſely, ſo as to form a head round, and to conceal the extremity of the wire entirely. This head of cotton muſt be rolled in powder of lycopodium, or, which anſwers better, in powder of roſin; by which means a good deal of the powder will ſtick to the cotton: this done, the jar is charged, and then the head of cotton, &c. is brought towards its knob rather quickly, ſo as to cauſe the jar to diſcharge through the cotton, by which means the cotton will be inſtantly ſet on fire, and will laſt long enough to light a candle thereby. This is a very pleaſing experiment, contrived by Dr. Ingenhouze.

To ſtrike Metals into Glaſs.

EXPERIMENT 11. Take two ſlips of common window-glaſs about three inches long, and half an inch wide; put a ſmall ſlip of gold, ſilver, or braſs leaf, between them, and tie them together, or elſe preſs them together between the boards of the preſs H, belonging to the univerſal diſcharger, *fig.* 6. Plate II. leaving a little of the metallic leaf, and the force of the exploſion will drive part of the metal into ſo cloſe a contact with the glaſs, that it cannot be wiped off, or even be affected by the common menſtrua, which otherwiſe would diſſolve it. In this experiment the glaſſes are often ſhattered to pieces; but whether they are broken or not, the indelible metallic tinge will always be found in ſeveral places, and ſometimes through the whole length of both glaſſes.

ARTICLE IV.

EXPERIMENTS WITH THE ELECTRICAL BATTERY.

The force of accumulated electricity, great as it appears by the experiments performed with a ſingle coated jar, is very ſmall when compared with that which is produced by a number of jars connected together; and if the effects of a ſingle jar are ſurpriſing, the prodigious force of a large battery is certainly aſtoniſhing. To obſerve that the metals, even the moſt purified platina, which reſiſts the greateſt efforts of chymic fire, are actually, and almoſt inſtantaneouſly rendered red-hot, and fuſed; to ſee animals deſtroyed; and to hear the loud report of a large electric battery, are things that always produce a kind of terror in the mind of an attentive obſerver. Experiments of this kind ſhould be conducted with great caution, and the operator ought to be attentive, not only to the buſineſs in hand, but alſo to the perſons who may happen to be near him, prohibiting their touching, or even coming too near any part of the apparatus; for if a miſtake in performing other experiments may be diſagreeable, thoſe in the diſcharge of a large battery may be attended with worſe conſequences. When a battery is to be charged, inſtead of a large prime conductor, a ſmall one is much more convenient; for, in this caſe, the diſſipation of the electricity is not ſo conſiderable. The quadrant-electrometer, *Fig.* 14. Plate II. which ſhews the height of the charge in the battery, may be fixed either upon the prime conductor, or upon the battery: in which latter caſe, it ſhould be placed upon a rod proceeding from the wires of the jars, and if the battery be very large, it ſhould be elevated two or three feet above them.

The index of the electrometer in charging a large battery will ſeldom riſe ſo high as 90°, becauſe the machine cannot charge a battery ſo high in proportion, as a ſingle jar. Its limit is often about 60° or 70°, more or leſs in proportion to the ſize of the battery, and the force of the machine. To increaſe the force of the electric exploſion, ſeveral Leyden phials are connected together in a box; this collection is termed an electrical battery. *Fig.* 34, repreſents one of the moſt approved form. The bottom of the box is covered with tin foil, to connect the exterior coatings; the inſide coatings of the jars are connected by the wires *b*, *c*, *d*, *e*, *f*, *g*, which meet in the large ball A; C is a hook at the bottom of the box, by which any ſubſtance may be connected with the outſide coating of the jars; a ball B proceeds from the inſide, by which the circuit may be conveniently completed. The following precautions are neceſſary to be attended to by thoſe who make uſe of an electrical battery. To keep the top and uncoated parts of the jars dry and free from duſt, and after the exploſion to connect a wire from the hook to the ball, which ſhould be left there till the battery is to be charged again, which will totally obviate the inconveniencies that have occaſionally happened from the reſiduum of a charge. If one jar in a battery is broke, it is impoſſible to charge the reſt till the broken jar is removed. A cracked jar may be made to receive a charge, by taking away the external and internal coatings which were over the crack, ſo as to leave a ſpace of about one fourth of an inch between the crack and remaining tin-foil. To prevent the jars of a large battery breaking at the time of the exploſion, it has been recommended not to diſcharge a battery through a good conductor, except the circuit is at leaſt five feet long; but what is gained on one hand by this method, is loſt on the other, for, by lengthening the circuit, the force of the ſhock is weakened proportionably. We have been informed, that it is very difficult to break by an exploſion the jars which are made of green glaſs, fabricated at Newcaſtle, but have had no opportunity to make any experiments on this glaſs ourſelves. The force of a battery may be conſiderably increaſed by concentrating the ſpark from the exploſion, which is effected by cauſing it to paſs through ſmall circuits of non-conducting ſubſtances. By this means the reſiſting medium, through which the ſpark is to paſs, may be ſo prepared as to augment its power. If the ſpark is made to paſs through a hole in a plate of glaſs, one twelfth or one ſixth part of an inch in diameter, it will be leſs diſſipated, more compact and powerful. If the part round the hole is wetted with a little water, the ſpark, by converting this into vapour, may be conveyed to a greater diſtance, with an increaſe of rapidity, attended with a louder noiſe than common. Mr. Morgan, by attending to theſe and ſome other circumſtances, has melted wires, &c. with ſmall bottles. We hope he will be induced to communicate this, as well as the reſt of his important diſcoveries, to the public.

Extraordinary Power of the Electric Battery.

EXPERIMENT 1. Let a quire of paper be ſuſpended by a line in the manner of a pendulum from any convenient altitude, ſo that its plane may be vertical. Let the largeſt charge from a battery be cauſed to paſs through it, while quieſcent in an horizontal direction perpendicular to the plane, the rods of communication not touching the paper; the phænomena are; firſt, the aperture cauſed by perforation, the leaves being protruded both ways from the middle: ſecond, not the ſmalleſt motion is communicated to the paper from the force of the diſcharge. A quire of the thickeſt and ſtrongeſt paper was made uſe of for this experiment, the height from which it was ſuſpended ſixteen feet. It is an extraordinary appearance on the hypotheſis of a ſingle electric fluid, that a force ſufficient to penetrate a ſolid ſubſtance of great tenacity and coheſive force, ſhould not communicate the ſmalleſt motion to the paper, when a breath of air would cauſe ſome ſenſible vibration in it. But this difficulty is not unanſwerable: for a velocity may be aſſigned, with which a body impinges againſt and paſſes through a pendulum of any given weight and reſiſting force, ſo that a ſmaller angular velocity ſhall be communicated to it, than any that ſhall be propoſed, and we know no limit to the velocity of the electric power or powers. But the other phenomenon, i. e. the oppoſite direction in which the leaves are protruded, tends very much to ſtrengthen the opinion of two oppoſite currents: perhaps either of thoſe phænomena, conſidered ſimply, may admit of an eaſy ſolution from the hypotheſis of a ſingle power; when they are taken both together, it ſeems more difficult to reconcile this hypotheſis with matter of fact.

If pieces of cork or any light bodies be placed near the exploſion of a jar or battery, they will be moved out of their place in all directions from the centre of the exploſion; and the greater the force of the exploſion, ſo much greater will the diſtance be to which they are removed. It is not ſurpriſing, therefore, that heavy bodies ſhould be removed to conſiderable diſtances by a ſtrong flaſh of lightning. Dr. Prieſtley apprehends, that this ſpecies of lateral force is produced by the exploſion of the air from the place through which the electric diſcharge paſſes.

To melt Wires.

EXPERIMENT 2. Connect with the hook, communicating with the outſide coating of a battery, containing at leaſt thirty ſquare feet of coated ſurface, a wire, that is one fiftieth part of an inch thick, and about two feet long; the other end of it muſt be faſtened to one end of the diſcharging rod; this done, charge the battery, and then by bringing the diſcharging rod near its wire, ſend the exploſion through the ſmall wire, which by this means will be made red-hot, and melted, ſo as to fall upon the floor in different glowing pieces. When a wire is melted in this manner, ſparks are frequently ſeen at a conſiderable diſtance from it, which are red-hot particles of the metal, that by the violence of the exploſion are ſcattered in all directions. If the force of the battery is very great, the wire will be intirely diſperſed by the exploſion, ſo that none of it can be afterwards found.

To make Globules of Metals.

EXPERIMENT 3. Take a very ſlender wire, and put it in a glaſs tube, about one quarter of an inch in diameter; then ſend the charge of a battery through it, and the wire will be melted, and reduced into globules of different ſizes, which are found ſticking on the inſide ſurface of the glaſs tube, and they may be eaſily ſeparated from it at pleaſure: theſe, upon examination, will all be found hollow, and are little more than a mere ſcoria of metal. It muſt be obſerved, in making this experiment, that the charge of the battery muſt neither be too high nor too weak; for in the former caſe, the wire will be reduced into pieces exceedingly ſmall, or rather exploded in ſmoke; and in the latter caſe, it will be imperfectly fuſed, ſo that its pieces will be large and irregular.

The Imitation of an Earthquake.

EXPERIMENT 4. The appearance of the earthquake, as repreſented with the exploſion of a battery, is occaſioned by the concuſſion given to ſeveral ſubſtances by the exploſion paſſing over their ſurfaces. To give a repreſentation of the impreſſion made upon houſes by the earthquake, ſmall ſticks, cards, or the like, may be placed upon the ſurface of the body over which the exploſion is to be tranſmitted, ſo as to ſtand very light. Theſe ſticks, &c. will never fail to be ſhook, and often to be thrown down by the exploſion. It is remarkable, that an exploſion will not paſs over the ſame length of ſurface of all bodies, though they are equally good conductors. Water, ice, wet wood, raw fleſh, and moſt of the animal fluids, are the beſt to make this remarkable experiment; to do which, nothing more is required than to inſert part of the ſurface of the ſaid ſubſtances into the circuit of the two ſides of a battery; a chain, for inſtance, communicating with the outſide, may be placed ſo as nearly to touch the ſurface of a quantity of water, and at about eight or nine inches diſtant from another chain, ſituated alſo very near the ſurface of the water, and communicating with one end of the diſcharging rod. If the ends of the chains touch the water, the experiment will happen in the ſame manner.

The report, in this experiment, is much louder than when the exploſion paſſes through the air only. The concuſſion given to the water, by the exploſion paſſing over its ſurface, is not only ſuperficial, but affects its whole body; and if the hand is kept deep under its ſurface whilſt the exploſion paſſes over it, the concuſſion may be very ſenſibly felt.

The ſpark, that in this experiment paſſes over the ſurface of the water, ſeems to bear a great reſemblance to the balls of fire that have ſometimes been ſeen over the ſurface of the ſea or land in time of an earthquake; and hence it ſeems very probable, that thoſe balls of fire are electrical phænomena.

ARTICLE V.

EXPERIMENTS ON THE INFLUENCE OF POINTS, AND THE USEFULNESS OF POINTED METALLIC CONDUCTORS, TO DEFEND BUILDINGS FROM THE EFFECTS OF LIGHTNING.

The reader, in the courſe of this Syſtem, muſt have obſerved in ſeveral of the experiments already deſcribed, the remarkable property that points have, both of throwing off and receiving ſilently the electric fluid; but in this article we ſhall deſcribe a few curious experiments of this kind, by which the influence of points, in reſpect to electricity, may be better underſtood, and which may, in a more particular manner, demonſtrate the utility of metallic conductors to houſes, or piles of building, in order to preſerve them from the damage often occaſioned by a ſtroke of lightning; which is one of the greateſt benefits that mankind has received from the ſcience of electricity.

Thunder Houſe.

EXPERIMENT 1. *Fig.* 35 repreſents the gable end of a houſe, fixed vertically on a board F G; a ſquare hole is made in the gable and at *h i*, into which a piece of wood is fitted; a wire is inſerted in the diagonal of this little piece; two wires are alſo fitted to the gable end; the lower end of one wire terminating at the upper corner of the ſquare hole: the top of the other wire is fixed to its lower corner; the braſs ball on the wire may be taken off, in order that the pointed end may be taken occaſionally expoſed to receive the exploſion. Place a jar with its knob in contact with the conductor, connect the bottom of the jar with the hook H, then charge the jar, and bring the ball under the conductor, and the jar will be diſcharged by an exploſion from the conductor to the ball of the houſe. The wires and chain being all in connection, the fire will be conveyed to the outſide of the jar, without affecting the houſe; but if the ſquare piece of wood is placed ſo that the wires are not connected, but the communication cut off, the electric fluid, in paſſing to the outſide of the bottle, will throw out the little piece of wood to a conſiderable diſtance, by the lateral force of the exploſion. See *Fig.* 35.

Unſcrew the ball, and let the point which is underneath be preſented to the conductor, and then you will not be able to charge the jar; for the ſharp point gradually draws the fire from the conductor, and conveys it to the coating on the outſide of the jar. The prime conductor is ſuppoſed to repreſent a thunder cloud diſcharging its contents on a weather-cock, or any other metal, at the top of a building. From this experiment many have inferred, that if there is a connection of metal to conduct the electric fluid down to the earth, the building will receive no damage; but where the connection is imperfect, it will ſtrike from one part to another, and thus endanger the whole building.

To diſcharge a Jar ſilently.

EXPERIMENT 2. When a large jar is fully charged, which would give a terrible ſhock, put one of your hands in contact with its outſide coating: with the other hold a ſharp-pointed needle, and, keeping the point directed towards the knob of the jar, proceed gradually near it, until the point of the kneedle touches the knob. This operation diſcharges the jar entirely, and you will either receive no ſhock at all, or ſo ſmall a one as can hardly be perceived. The point of the kneedle, therefore, has ſilently and gradually drawn all the ſuperfluous fluid from the inſide ſurface of the electric jar.

Powder Houſe.

EXPERIMENT 3. *Fig.* 32 is a perſpective view of the powder houſe; the ſide of the roof next the eye being omitted, that the inſide may be more conveniently ſeen. The front of this model is fitted up like the thunder houſe, and is uſed in the ſame manner; the ſides of the houſe, the back, and fore-front, are joined to the bottom by hinges; the roof is divided into two parts, which are alſo faſtened by hinges to the ſides; the building is kept together by a ridge on the roof; when the roof is blown up, it will fall down with the ſides, the back, and the fore-front. To uſe this model, fill the ſmall tube *a* with gun-powder, and ram the wire *c* a ſmall way in the tube, then connect the hook *e* with the bottom of a large jar or battery; when the jar is charged, form a communication from the hook *d* to the top of the jar; the diſcharge will fire the powder, and the exploſion of the gun-powder will throw off the roof, and the ſides, the fore and back fronts will then all fall down.

EXPERIMENT 4. Mr. Henly ſuſpended by a ſilk ſtring, from one end of a wooden bar, which turned freely in an horizontal direction upon the point of a needle, a large bullock's bladder, gilded with leaf copper; the bladder was ballanced by a weight at the other end of the arm; (ſee *fig.* 29;) he gave a ſtrong ſpark from the knob of a charged phial to the bladder; he then preſented towards it a braſs ball, two inches in diameter, and obſerved that the bladder would come towards it at that diſtance of three inches; and when it got within an inch, would throw off it's electricity in a full ſpark. He then gave it another ſpark, and preſented a pointed wire towards the bladder, which never approached to the point, nor ever gave any ſpark, the electricity being carried off.

The Electric Fly.

EXPERIMENT 5. Fix a pointed wire in the hole on the upper ſide of the conductor, then place the center of the braſs croſs *b*, *fig.* 23, upon the point, the ends of which croſs are all bent one way; electrify the conductor, and the croſs will turn upon its center with great rapidity. If the room be darkened, a circle of light will be formed by the electric fluid on the points of the wires. The re-action of the air on the diverging cone of electric matter, gives the retrograde motion to the points of the wire. The fly turns round in the ſame direction, whether it is electrified negatively or poſitively; though it will not move in vacuo, unleſs the finger, or ſome other conductor, is applied to the glaſs receiver oppoſite to one of the points, it will then begin to move, and continue to do ſo briſkly till the glaſs is charged.

Fig. 24 repreſents a ſmall crane, which will move from the ſame cauſe as the foregoing, and raiſe a ſmall weight. Several flyers may be made to turn at the ſame time, and many other pleaſing experiments may be contrived on the ſame principle; or, the flyers may be placed one above another, as in *fig.* 23, diminiſhing gradually in ſize, and forming when electrified a luminous cone; the circles of light will be more brilliant, if the ends of the wires are covered with a thin coating of greaſe, ſealing-wax, or ſulphur.

Various Objects put in Motion by electrified Points.

EXPERIMENT 6. If ſmall boats or little ſwans, &c. are made of cork or light wood, they may be attracted, and made to ſwim in any direction, by applying a finger towards them; a fine needle ſtuck into the end of the boats, in the manner of a bowſprit, will cauſe them to be repelled from the hand held over it, and they may be ſteered by it, ſtern foremoſt, to what point of the compaſs you pleaſe. The boats might have the addition of ſails to them, and might then be made to move briſkly before an electrical gale, from the point of a wire held in the hand. The operator in theſe tricks would certainly be looked upon as a magician, if the electrical machine is kept out of ſight. But a more ſtriking ſight, would be a number of theſe boats, with each of them a twirling fly, about an inch in length, fixt to the top of the maſt; the hand held over them would ſet them all in motion: in the dark, they would appear as ſo many rings of fire, moving in various courſes, and following the hand in any direction.

When a few young perſons have nothing elſe to do, they might very innocently amuſe themſelves, by making a repreſentation of a kind of ſea-engagement between theſe boats. Suppoſing each of them large enough to hold a ſmall coated phial without ſinking, theſe phials may be charged, ſome of them poſitively on the inſide, others negatively; they may then be placed at the bow of the boat, with the wire ball and uncoated part of the phial projecting over; a ſmall braſs chain ſhould be made to touch the outward coating of the phial, and the other end brought over the ſtern of the boat, and hang ſo as to touch the water. The boats being then put into a trough of water, and pretty highly charged, they will ſoon be in motion; thoſe that are electrified alike, will repel each other; and thoſe poſſeſſed of a contrary electricity, will be attracted, till the balls of the two phials approach pretty near together; they will then diſcharge their contents with a loud exploſion, and the boats will afterwards ſheer from each other. Becket's Eſſay on Electricity, p. 36.

When the electric fluid percolates a wooden point, the ſtream or cone, which iſſues from it, ſeems diluted, and ſomething ſimilar to the purple electric light, which is obtained in vacuo. The action of the electric fluid on the air, by an electrified point, produces a ſenſible aura, or wind of ſufficient force, as is ſeen above, to put light bodies in motion, or diſturb the flame of a candle, and occaſion an undulation in the fluids: the action of the fluid is ſo modified by points, as to produce an agreeable ſenſation, reſembling a gentle breathing: this ſenſation may be rendered more or leſs ſtimulating, by the reſiſtance the fluid meets with in its action on our bodies, an effect which is productive of great advantages in medical electricity.

ARTICLE VI.

EXPERIMENTS AND OBSERVATIONS ON ATMOSPHERICAL ELECTRICITY, BY MR. CAVALLO.

Theſe were principally made with an electrical kite, which will collect electricity from the air at any time. The power of this inſtrument reſides in the ſtring. The beſt method of making the ſtring is by twiſting two threads of common twine with one of that copper thread which is uſed for trimming: a ſchoolboy's kite with this ſtring anſwers the purpoſe as well as any other. When a kite conſtructed in this manner was raiſed, Mr. Cavallo ſays he always obſerved the ſtring to give ſigns of electricity, except once; the weather was warm, and the wind ſo weak, that the kite was raiſed with difficulty, and could hardly be kept up for a few minutes: afterwards, when the wind increaſed, he obtained as uſual a ſtrong poſitive electricity. If this kite was raiſed at a time when there was any probability of danger from the great quantity of electricity, Mr. Cavallo connected one end of a chain with the ſtring, and let the other end fall on the ground, and placed himſelf alſo on an inſulating ſtool. Except the kite is raiſed in a thunder-ſtorm, there is no great danger that the operator will receive a ſhock. Although he raiſed his kite hundreds of times without any precaution whatever, he ſeldom received even a few ſlight ſhocks in the arms. But it is not adviſeable to raiſe it while ſtormy clouds are over head. This is alſo leſs neceſſary, as the electricity of the atmoſphere may then be eaſily obſerved by other means.

When the kite was raiſed, he often introduced the ſtring through a window into a room of the houſe, and faſtened it by a ſtrong ſilk lace to a heavy chair in the room. A ſmall prime conductor, which, by means of a ſmall wire, is connected with the ſtring of the kite; a quadrant electrometer is fixed upon an inſulating ſtand, and placed near the prime conductor; a glaſs tube about 18 inches long, a ball and a wire of braſs, are fixed to a glaſs tube. This ſmall inſtrument is uſeful to determine the quality of the electricity, when it is not ſafe to come near the ſtring. This is effected by touching the ſtring with the wire, which takes a ſufficient quantity from it to aſcertain thereby the quality of the electricity, either by the attraction and repulſion of light balls, or the appearances of the electric light: or it may be aſcertained by a Leyden phial, which will retain a charge for a conſiderable time; and then the kite need not be kept up any longer than is neceſſary to charge the phial, by which the quality will be ſhewn even at ſome days diſtance.

If a charged phial is carefully kept from any of thoſe means by which it is known to be diſcharged, it will retain its charge for a long time. On this principle the above-mentioned phial is conſtructed; the bottle is coated in the uſual manner; the uncoated part of the glaſs is covered with wax, or elſe well varniſhed; a glaſs tube, which is open at both ends, is cemented into the neck of this phial, having a piece of tin foil connected with its loweſt extremity, which touches the inſide non-electric coating. A glaſs handle is fixed to the ball on the wire which paſſes into a glaſs tube; the wire is of a proper length to touch the tin-foil which is at the bottom of the tube. Charge this bottle in the uſual manner, and then take out the wire from the glaſs tube by means of the glaſs handle. This may be done without diſcharging the phial; and, as the fire cannot now eſcape eaſily, the charge of a phial may be preſerved for many weeks.

Fig. 31 repreſents a very ſimple inſtrument (contrived by Mr. Cavallo) for making experiments on the electricity of the atmoſphere, and which, on ſeveral accounts, appears to be the beſt for the purpoſe. A B is a common jointed fiſhing rod, without the laſt or ſmalleſt joint: from the extremity of this rod proceeds a ſmall glaſs tube C, covered with ſealing wax, a cork D is fixed at the end of it, from which an electrometer with pith balls is ſuſpended. HGI is a piece of twine faſtened to the other extremity of the rod, and ſupported at G by a ſmall ſtring F G. At the end of the twine T a pin is faſtened, which, when puſhed into the cork D, renders the electrometer E uninſulated. When the electricity of the atmoſphere is obſerved with this inſtrument, thruſt the pin T into the cork D, and hold the rod by the lower end A; place it out of a window at the upper part of the houſe, raiſing the end of the rod with the electrometer, ſo as to make an angle of 50 or 60 degrees with the horizon. Keep the inſtrument in this ſituation for a few ſeconds, then pull the twine at H, and the pin will be diſengaged from the cork D; which operation cauſes the ſtring to drop in the dotted ſituation KL, and leaves the electrometer inſulated, and electrified with an electricity contrary to that of the atmoſphere. This being done, you may draw the electrometer into the room, and examine the quality of the electricity, without obſtruction either from wind or darkneſs.

Fig. 30 is an electrometer for rain, contrived by Mr. Cavallo. ABCT is a ſtrong glaſs tube, about two feet and a half long, having a tin funnel DE cemented to its extremity, which funnel defends part of the tube from the rain. The outſide ſurface of the tube from A to B is covered with ſealing-wax, and ſo is the part of it which is covered by the funnel. FD is a piece of cane, round which braſs wires are twiſted in different directions, ſo as to catch the rain eaſily, and at the ſame time to make no reſiſtance to the wind. This piece of cane is fixed into the tube, and a ſmall wire proceeding from it goes through the tube, and communicates with the ſtrong wire AG, which is thurſt into a piece of cork, faſtened to the end A of the tube. The end G of the wire AG is formed into a ring, from which a ſenſible pith ball electrometer is to be ſuſpended. This inſtrument is faſtened to the ſide of a window frame, where it is ſupported by ſtrong braſs hooks at CB; which part of the tube is covered with a ſilk lace, in order to adapt it better to the hooks. The part FL is out of the window, with the end F elevated a little above the horizon. The remaining part of the inſtrument comes through a hole in one of the lights in the ſaſh, within the room, and no more of it touches the ſide of the window than the part CB. When it rains, eſpecially in paſſing ſhowers, this inſtrument is frequently electrified; and by the divergence of the electrometer, the quantity and quality of the rain may be obſerved without any danger of a miſtake. With this inſtrument, in rainy weather, Mr. Cavallo has been able to charge a ſmall coated phial at the wire AG. It ſhould be fixed in ſuch a manner, that it may be eaſily taken off from the window, and replaced again, as occaſion requires; as it will be neceſſary to clean it often, particularly when a ſhower of rain is approaching.

Mr. De Sauſſure's Atmoſpherical Electrometer, with Experiments to illuſtrate its Effects.

The electrometer *fig.* 16, Plate 2, is nearly the ſame as that of Mr. Cavallo's; it may be uſed inſtead of the condenſer of M. Volta, by only placing it on a piece of oiled ſilk, ſomewhat larger than the baſe of the inſtrument; but in this caſe, it is the baſe, and not the top of the inſtrument, which muſt be brought into contact with the ſubſtance whoſe electricity is to be explored. The following are the moſt material circumſtances in which they differ; firſt, the fine wires, by which the balls are ſuſpended, ſhould not be long enough to reach the tinfoil which is paſted on the inſide of the glaſs, becauſe the electricity, when ſtrong, will cauſe them to touch this tinfoil twice conſecutively, and thus deprive them in a moment of their electricity. To prevent this defect, and yet give them a ſufficient degree of motion, it is neceſſary to uſe larger glaſſes than thoſe that are generally applied to Mr. Cavallo's Electrometer; two or three inches diameter will be found to anſwer the purpoſe very well. But as it is neceſſary to carry off the electricity which may be communicated to the inſide of the glaſs, and thus be confounded with that which belongs to thoſe ſubſtances that are under examination; four pieces of tinfoil ſhould be paſted on the inſide of the glaſs; the balls ſhould not be more than 1-20th of an inch diameter, ſuſpended by ſilver wire moving freely in holes nicely rounded. The bottom of the electrometer ſhould be of metal: for this renders it more eaſy to deprive them of any acquired electricity, by touching the bottom and top at the ſame time.

In order to collect a great quantity of electricity from the air, the electrometer is furniſhed with a pointed wire 15 inches, or two feet long, which unſcrews in three or four pieces, to render the inſtrument more portable; ſee *fig*. 16. When it rains or ſnows, a ſmall parapluie, is to be ſcrewed on the top of the inſtrument, as by this its inſulation is preſerved, notwithſtanding the rain. This inſtrument indicates not only the electricity of fogs, but that alſo of ſerene weather, and enables us to diſcover the kind of electricity which reigns in the atmoſphere; and to a certain degree, to form an eſtimate of its quantity, and that under two different points of view, the degree of intenſity, and the diſtance from the earth at which it firſt begins to be ſenſible.

Mr. Abraham Bennett's Atmoſpherical Electrometer with Experiments to illuſtrate its Effects.

Fig. 17, repreſents an improvement of the atmoſpherical electrometer, by Mr. Abraham Bennett, of Wirkſworth, Derbyſhire; it was tranſmitted to us by a very ingenious friend. The principal advantage of this little inſtrument, is the delicacy of the materials of which it is compoſed.

It conſiſts of two ſlips of leaf gold, which are paſted to the ſides of a peg, which fits into a ſmall tube, in the under ſide of the cap. The cap, or cover, is flat, in order that plates, books, or other articles, on which experiments are to be made, may be placed upon it. It has alſo a rim to keep off the rain, and maintain the inſulation, when it is uſed in the open air. There is a ſmall tube on one ſide of the cap, to fix wire or any other occaſional ſubſtance to; the pieces of leaf gold are about 3 inches long, and 1-5th of an inch broad. The cover may be taken off at pleaſure, to repair any accident happening to the leaf gold. The glaſs prevents the leaf gold from being agitated; two pieces of tinfoil are faſtened on oppoſite ſides of the internal ſurface of the glaſs, to prevent the glaſs from being charged, and thus interfering with the repulſion of the electrometer; therefore the cover ſhould be ſo turned, that the leaf gold may ſtrike againſt the tin-foil. The following experiment ſhews the great ſenſibility of this little inſtrument.

The ſenſibility of this inſtrument may be increaſed, by placing a candle upon the cap; by this means a cloud of chalk, which would but juſt open the leaf gold before, will cauſe them to ſtrike the ſides for a long time together, and the electricity is now communicated ſo ſtrong, that the leaves will be repelled by a ſtick of excited wax at 10 or 12 inches diſtance. A cloud of chalk made in one room will electrify this inſtrument, brought from another room, and at a conſiderable diſtance. Excited ſealing-wax will often make the leaf gold ſtrike the ſides of the glaſs more than 12 times; when the ſealing-wax recedes, it will ſtrike it again, nearly the ſame number of times; but if the approach is quicker than the receſſion, the number of times will ſometimes be greater. The quantity of electricity neceſſary to cauſe a repulſion of the leaf gold is ſo ſmall, that the ſharpeſt points or edges do not draw it off, unleſs they are brought into contact with it: hence it is unneceſſary to avoid points or edges in the conſtruction of this inſtrument. In ſome experiments, a candle may be connected at the ſame time by a wire with the upper part of the electrometer; and they increaſe the advantages to be obtained from it. When this apparatus is uſed, the operator muſt touch the metallic handle, and the electricity will enter by the candle, between the cap and upper plate; this being lifted up, the inſtrument will exhibit the electricity.

Of the Electric Properties of the Torpedo, Gymnotus Electricus, and Silurus Electricus.

The electric power, by the ancients obſerved only in amber, and perhaps in the tourmalin, was in proceſs of time found to be produced by glaſs, ſulphur, reſins, ſilk, and divers other bodies. It has been within theſe forty years that its great influence has been diſcovered in the atmoſphere; and not yet twenty five years ſince that power has been obſerved even in the animal kingdom. Three fiſhes have hitherto been diſcovered to have the ſingular property of giving ſhocks analogous to thoſe of artificial electricity, namely, the *torpedo*, the *gymnotus electricus*, and the *ſilurus electricus*.

The ancients indeed were acquainted with this wonderful property of the firſt, and probably of the laſt of thoſe animals, and it was from the property of giving that ſhock, benumbing ſenſation, or *torpor*, that they called the firſt *torpedo*; but they were utterly ignorant of the cauſe of it. Two diſtinguiſhed writers of the laſt century endeavoured to explain this property upon mechanical laws, but their ingenuity was inſufficient to anſwer for the phenomenon. The principal diſcoveries, relating to the identity of the abovementioned property of thoſe fiſhes and the electric ſhock, were made by John Walſh, Eſq. F. R. S. to whoſe ingenuity we are indebted for the demonſtration of the power of the torpedo agreeing with the electric ſhock in all the points of compariſon in which it could be examined; and alſo for almoſt all the other diſcoveries which were ſince made relating to animal electricity. The three animals which, whilſt alive, are poſſeſſed of an electric power, are belonging to three different orders of fiſh; and the few particulars, which they ſeem to have in common, are the power of giving the ſhock; an organ in their body, now called the electric organ, which is employed by the animals for the exertion of that power; a ſmooth ſkin without ſcales; and ſome ſpots here and there on the ſurface of their bodies.

1. *Torpedo.*

The torpedo, which belongs to the order of rays, is a flat fiſh, very ſeldom twenty inches in length, weighing not above a few pounds when full grown, and pretty common in various parts of the ſea-coaſt of Europe. The electric organs of this animal are two in number, and placed one on each ſide of the cranium and gills, reaching from thence to the ſemicircular cartilages of each great fin, and extending longitudinally from the anterior extremity of the animal to the tranſverſe cartilage which divides the thorax from the abdomen.

The magnitude and the number of the electric nerves beſtowed on organs, in proportion to their ſize, muſt on reflection appear as extraordinary as the phenomena they afford. Nerves are given to parts either for ſenſation or for action. Now if we except the more important ſenſes of ſeeing, hearing, ſmelling, and taſting, which do not belong to the electric organs, there is no part, even of the moſt perfect animal, which, in proportion to its ſize, is ſo liberally ſupplied with nerves; nor do the nerves ſeem neceſſary for any ſenſation which can be ſuppoſed to belong to the electric organs; and, with reſpect to action, there is no part of any animal, with which we are acquainted, however ſtrong and conſtant its natural actions may be, which has ſo great a proportion of nerves.

Thus far with the anatomical deſcription of the animal; we ſhall now proceed to deſcribe its wonderful electric properties. The above-deſcribed electric organs ſeem to be the only parts employed to produce the ſhock; the reſt of the animal appearing to be only the conductor of that ſhock, as parts adjacent to the electric organs; and in fact, by artificial electricity, it has been found that the animal is a conductor of the electric fluid. The two great lateral fins which bound the electric organs laterally, are the beſt conductors.

If the torpedo, whilſt ſtanding in water or out of the water, but not inſulated, be touched with one hand, it generally communicates a trembling motion or ſlight ſhock to the hand, but this ſenſation is only felt in the fingers of that hand. If the torpedo be touched with both hands at the ſame time, one hand being applied to its under, and the other to its upper ſurface, a ſhock in that caſe will be received, which is exactly like that occaſioned by the Leyden phial. When the hands touch the fiſh on the oppoſite ſurfaces, and juſt over the electric organs, then the ſhock is the ſtrongeſt; but if the hands are placed in other parts of the oppoſite ſurfaces, the ſhocks are ſomewhat weaker, and no ſhock at all felt when the hands are both placed upon the electric organs of the ſame ſurface; which ſhews that the upper and lower ſurfaces of the electric organs are in oppoſite ſtates of electricity, anſwering to the *plus* and *minus* ſides of a Leyden phial. When the fiſh is touched by both hands on the ſame ſurface, and the hands are not placed exactly on the electric organs, a ſhock though weak is ſtill received, but in that caſe the oppoſite power of the other ſurface of the animal ſeems to be conducted over the ſkin.

The ſhock given by the torpedo when the air is about four times as ſtrong as when in water; and when the animal is touched on both ſurfaces by the ſame hand, the thumb being applied to one ſurface, and the middle finger to the oppoſite ſurface, the ſhock is felt much ſtronger than when the circuit is formed by both hands. Sometimes the torpedo gives the ſhock ſo quickly one after the other as ſcarcely to elapſe two ſeconds between them; and when, inſtead of a ſtrong determined ſtroke, it communicates only a torpor, that ſenſation is juſtly attributed to the ſucceſſive and quick diſcharge of many conſecutive ſmall ſhocks. It is very ſingular, that the torpedo, even when inſulated, ſhould be capable of giving a great many ſhocks to perſons likewiſe inſulated. This power of the torpedo is conducted by the ſame ſubſtances which conduct electricity, and is interrupted by the ſame ſubſtances which are not conductors of electricity: hence if the animal, inſtead of being touched immediately with the hands, be touched by non-electrics, as wire, two wet cords, or other conductors of electricity, held in the hands of the experimenter, the ſhock will alſo be communicated through them. The circuit may alſo be formed by ſeveral perſons joining hands, and the ſhock will be felt by them all at the ſame time. When the animal is in water, if the hands are put in water, a ſhock will alſo be felt, which will be ſtronger if one of the hands be brought quite into contact with the fiſh, whilſt the other hand is kept in the water at a diſtance from it. In ſhort, the ſhock of this animal is conducted by the ſame conductors which conduct that of a Leyden phial. This ſhock of the torpedo may be alſo be conducted by ſeveral circuits at once, and the circuit may be conſiderably extended; but the ſhock is always weakened by lengthening or multiplying the circuit

The ſhock of the torpedo cannot paſs through the leaſt interruption of continuity in the conductors which form the circuit; ſo that it will not be conducted by a chain, nor will it paſs through the air from one conductor to the other, when the diſtance between them is leſs than the two hundredth part of an inch; conſequently no ſpark has ever been obſerved to accompany it. No electric attraction or repulſion could be ever obſerved to be produced by the torpedo, nor, indeed, by any of the electric fiſhes; though ſeveral experiments have been purpoſely made with them. Theſe ſhocks of the torpedo ſeem to depend on the will of the animal; for each effort is accompanied with a depreſſion of his eyes, by which even his attempts to give it to non-conductors may be obſerved. It is not known whether both electric organs muſt always act together, or only one of them may be occaſionally put in action by the will of the animal. All theſe effects of the torpedo may be imitated by means of a large electric battery weakly charged, and furniſhed with Mr. Lane's Electrometer, *fig.* 4, Plate I, the balls of which muſt be put exceedingly near, or almoſt in contact with each other. But the properties of the gymnotus electricus, which we are going to deſcribe next, will throw more light on thoſe of the torpedo, and will ſhew much more evidently their analogy with the power of the electric fluid diſperſed through a vaſt ſurface of coated electric ſubſtance. "But," ſays Mr. Walſh, "after the diſcovery that a large area of rare electricity would imitate the effect of the torpedo, it may be inquired, where is this large area to be found in the animal? We here approach to that veil of nature, which man cannot remove. This, however, we know, that from infinite diviſion of parts infinite ſurface may ariſe, and even our groſs optics tell us, that thoſe ſingular organs, ſo often mentioned, conſiſt, like our electric batteries, of many veſſels, call them cylinders or hexagonal priſms, whoſe ſuperficies taken together furniſh a conſiderable area."

2. *The Gymnotus Electricus.*

The gymnotus electricus has been frequently called electrical eel, on account of its ſuperficial reſemblance to the common eel; though, when accurately examined, it is found to have none of the ſpecific properties of that animal. The gymnotus is found pretty frequently in the great rivers of South America. Its uſual length is about three feet; but it has been ſaid ſome of them have been ſo large, as to be able to ſtrike a man dead with the ſhock of their electric organs. A few of theſe animals were brought to England about ten years ago, which, as far as we know, were the firſt of the kind brought to Europe. They had been catched in Surinam river, a great way above where the ſalt-water reaches. It was with thoſe identical fiſhes that Mr. Walſh made many diſcoveries relating to their electrical properties, and the experiments which ſhew thoſe properties were publicly exhibited in London, during ſeveral months. The ſubject of animal electricity was conſiderably advanced by the diſcovery of the ſpark, with which the ſhock of the gymnotus was attended; for, notwithſtanding the previous diſcoveries relating to the torpedo, and the actual poſſibility of imitating the effects of that animal's extraordinary power by means of a large battery weakly charged with artificial electricity, yet the ſcrupulous philoſophers ſtill ſuſpected that the power of the torpedo might be ſomething different from electricity, ſince the two principal characteriſtics of electricity, namely the ſpark and the attraction, had never been diſcovered in the torpedo; and at the ſame time it was difficult to conceive the manner in which the electric fluid might be generated, accumulated, and diſcharged in an animal, which, at leaſt in its uſual ſtate of exiſtence, is a conductor of electricity, and is ſurrounded by a fluid which is likewiſe a conductor of that power. This indeed ſtill remains a profound ſecret; and it is difficult to ſay, whether any future experiments will ever diſcloſe it. But the ſpark having been diſcovered with the gymnotus, the analogy between its power and electricity is rendered conſiderably more evident, and it would be ſcepticiſm to doubt, of the property of the torpedo being derived from the ſame cauſe as that of the gymnotus. In order to proceed regularly, we ſhall now begin with the deſcription of the animal, and ſhall then enumerate its electric properties, in a very conciſe manner.

A gymnotus of three feet length, is generally between ten and fourteen inches in circumference, about the thickeſt part of its body. The electric power of this animal being much greater than that of the torpedo, its electric organs are accordingly a great deal larger, and indeed that part of its body which contains moſt of the animal parts, or the parts common to the ſame order of fiſhes, is conſiderably ſmaller than that which is ſubſervient to the electric power; though the latter muſt naturally derive nouriſhment and action from the former.

This animal has two pair of electric organs, one pair being larger than the other, and occupying moſt of the longitudinal parts of the body. They are divided from each other by peculiar membranes. "The ſtructure of theſe organs is extremely ſimple and regular, conſiſting of two parts, viz. flat partitions or ſepta, and croſs diviſions between them. The outer edges of theſe ſepta appear externally in parallel lines nearly in the direction of the longitudinal axis of the body. Theſe ſepta are thin membranes placed nearly parallel to one another: their lengths are nearly in the direction of the long axis, and their breadth is nearly the ſemidiameter of the body of the animal. They are of different lengths, ſome being as long as the whole organ. The nerves which go to the electric organs of the gymnotus, as well as of the torpedo, are much larger than thoſe which ſupply any other part of the body. The electric organs of the gymnotus are ſupplied with nerves from the ſpinal marrow, and they come out in pairs between the vertebræ of the ſpine.

The gymnotus poſſeſſes all the electric properties of the torpedo, but in a ſuperior degree. His ſhock is conducted by the conductors of electricity, and interrupted by the non-conductors of the electric fluid. Hence the ſhock is communicated through water, without the immediate contact of the animal, or through any other proper circuit; but the ſtronger ſhock is received by touching the animal when out of the water; and the beſt way to receive ſtrong ſhocks, is to apply one hand towards the tail, and the other towards the head of the animal. In this manner ſhocks have been felt not only in the arms, but even very forcibly in the breaſt. If the animal be touched only with one hand, then a kind of tremor is felt only in that hand, which though ſtronger, is quite analogous to the ſenſation communicated by the torpedo when touched in the like manner. The gymnotus's power of giving ſhocks is alſo depending on the will of the animal, ſo that ſometimes he gives very ſtrong ſhocks, and at other times very weak ones, but he gives the ſtrongeſt ſhocks when provoked by being frequently and roughly touched.

When ſmall fiſhes are put into the water wherein the gymnotus is kept, they are generally ſtunned or killed by a ſhock, and then they are ſwallowed, if the animal is hungry. The fiſhes which are ſtunned by the gymnotus may often be recovered by being ſpeedily removed into another veſſel of water. The ſtrongeſt ſhocks of the gymnotus will paſs a very ſhort interruption of continuity in the circuit. Thus they will be conducted by a chain, eſpecially when it is not very long, and is ſtretched, ſo as to bring its links into better contact. When the interruption is formed by the inciſion made by a pen-knife on a ſlip of tin-foil that is paſted on glaſs, and that ſlip is put into the circuit, the ſhock in paſſing through that interruption will ſhew a ſmall but vivid ſpark, plainly diſtinguiſhable in a dark room. Several other particulars, not only concurring to prove the above-mentioned property, but otherwiſe intereſting, were aſcertained by Mr. Walſh; but for theſe we muſt wait till that ingenious gentleman will favour the public with a particular account of his reſearches.

3. *The Silurus Electricus.*

This is the third fiſh which is known to have the power of giving the ſhock; it is found in the rivers of Africa, but we have a very imperfect account of its properties. Meſſrs. Adanſon and Forſkal, make a ſhort mention of it, and Mr. Brouſſonet deſcribes it, under the French name of *le Trembleur*, in the Hiſt. de l'Academie Royale des Sciences, for the year 1782. This animal belongs to the order which the naturaliſts call *ſilurus*; hence it is commonly called *ſilurus electricus*. Some of thoſe fiſhes have been ſeen even above twenty inches long. The ſilurus electricus is oblong, ſmooth, and without ſcales; being rather large, and flattened towards its anterior part. The colour of the body is greyiſh, and towards the tail it has ſome blackiſh ſpots.

The electric organ ſeems to be towards the tail, where the ſkin is thicker than on the reſt of the body, and a whitiſh fibrous ſubſtance, which is probably the electric organ, has been diſtinguiſhed under it. It is ſaid that the ſilurus electricus has the property of giving a ſhock or benumbing ſenſation like the torpedo, and that this ſhock is communicated through ſubſtances that are conductors of electricity; but no other particular about it is known with any conſiderable degree of certainty. An inquiſitive mind will immediately enquire, for what purpoſe has nature furniſhed thoſe animals with ſo ſingular a property? But the preſent knowledge of the ſubject ſeems to furniſh no other anſwer, except, that they are endowed with the power of giving the ſhock for the ſake of ſecuring their prey, by which they muſt ſubſiſt, and perhaps of repelling larger animals, which might otherwiſe annoy them. The ancients conſidered the ſhocks given by the torpedo as capable of curing various diſorders; and a modern philoſopher will hardly heſitate to believe their aſſertions, after that electricity has been found to be a remedy for many diſeaſes.

As Medical Electricity relates rather to the cure of diſorders than the explanation or elucidation of its ſeveral properties; and as I never practiſed Electricity medicinally, have reſigned it to the gentleman who is engaged to compoſe the Syſtem of Medicine, a taſk to which, from the nature of his profeſſion and his knowledge of the ſubject, he is far more competent than I am.

In forming this Syſtem, I have made ſeveral extracts from Mr. Cavallo's *learned and ingenious Treatiſe, but more particularly from Mr.* Adams's Practical Eſſay, *and acknowledge myſelf indebted to that work for the principal part of the entertaining experiments I have ſelected. I wiſhed to introduce many more from the ſame valuable collection; but as they would have far exceeded the œconomy of our plan, I have been under the neceſſity of omitting them.*

Thoſe who are inclined to enter more fully into an inveſtigation of the ſcience, I ſhall refer to Cavallo *and* Adams. *With reſpect to the apparatus uſed in performing the various experiments, the reader may ſelect ſuch as he thinks will beſt anſwer his purpoſe from Mr.* Adams's Catalogue, *affixed to No.* 66, *of this Work, with the price annexed to each article. As to the ſeveral uſes and applications of the Apparatus, Mr.* Adams *will moſt readily communicate any information that may be required.*

N° 19, *Ludgate Hill.*

HENRY HAGGARD.

ELECTUARY, in pharmacy, a form of medicine, compoſed of powders and other ingredients, incorporated with ſome conſerve, honey, or ſyrup; to be divided into doſes, like boluſes, when taken.

ELEEMOSYNÆ is uſed for the poſſeſſions belonging to churches. See ALMS.

ELEEMOSYNARIUS, in our old writers, is uſed for the almoner, or peculiar officer who received the eleemoſynary rents and gifts, and diſtributed them to pious and charitable uſes. There was ſuch an officer in all religious houſes. The biſhops alſo uſed to have their almoners, as now the king has. Linn. Provinc. Lib. i. tit. 12. See alſo Du-Cange, Gloſſ. Lat.

ELEEMOSYNARY *Corporations*. See CORPORATIONS.

ELEGANCE, ELEGANCY, from *eligo, I chuſe*, denotes a manner of doing, or ſaying things politely, agreeably, and with choice. With choice, ſo as to riſe above the common manners; politely, ſo as to ſtrike people of delicate taſte; and agreeably, ſo as to diffuſe a reliſh which gratifies every body.

ELEGANCE, in oratory, is one of the three parts of general elocution, and reſpects the purity and perſpicuity of the language. By the former a diſcourſe is rendered correct, and by the latter intelligible; and both extend to the ſelection of ſingle words, as well as to their conſtruction in ſentences. See Treatiſe on the Art of ORATORY.

Poetical elegancies, *elegantiæ poeticæ*, are of ſervice to ſcholars in making their verſes; by being too regular in the grammatical conſtruction, we loſe certain licences, wherein the elegance of language conſiſts. Elegance, though irregular, is better than regularity without elegance. The elegance of a painting is not founded on the correctneſs of the deſign, as appears in Raphael, and the antique. It is moſt felt in works otherwiſe careleſs and inaccurate; as in Correggio, where, in ſpite of all the defects as to juſtneſs of deſign, there is an elegance even in the manner of the deſign itſelf, as well as in the turn of the attitudes, &c. The elegance of a deſign is a manner which embelliſhes and heightens objects, either as to their form, or colour, or both; without deſtroying or perverting the truth.

ELEGIAC, in ancient poetry, ſomething that belongs to elegy. Elegiac verſes, Ελεγοι, are alternately hexameter, and pentameter. Quintilian eſteems Tibullus the chief of the elegiac poets; but the younger Pliny gives the preference to Propertius. They have each of them reaſon on their ſide; and one might make a third choice, as juſt as either of them. See ELEGY.

ELEGY, Ελεγεια, a mournful, and plaintive kind of poem. Voſſius, after Didymus, derives the term from ἒ, ἒ, λεγειν, *to ſay alas!* The firſt inventor of the elegy is not known: ſome ſay it was one Theocles of Naxus, or, according to others, of Eretria, who, in the heat of his phrenſy, firſt produced this kind of compoſition. But there is no wonder that we are at this time in the dark as to the matter; Horace aſſures us it was a point not ſettled among the grammarians, even in his time, who the author was.

> *Quis tamen exiguos* elegos *emiſerit auctor,*
> *Grammatici certant, & adhuc ſub judice lis eſt.*

The chief writers of elegy among the Greeks, are Callimachus, Parthenius, and Euphorion; and among the Latins, Ovid, Catullus, Tibullus, and Propertius. The Flemiſh have diſtinguiſhed themſelves among the moderns for this kind of Latin verſe. The elegies of Bidermann, Grotius, and eſpecially Sedronius and Vallius, ſeem worthy of the pureſt antiquity. The counteſs de la Suze has diſtinguiſhed herſelf for elegies in the French tongue. In the Engliſh, we have nothing conſiderable of the elegiac kind, but what we have in Milton. The Engliſh and French elegies are chiefly in Alexandrine verſes. In proceſs of time, elegy degenerated from its original intention; and not only matters of grief, but alſo joy, wiſhes, prayers, expoſtulations, reproaches, and almoſt every ſubject, were admitted into elegy. The office of elegy is well delivered by M. Boileau.

> *La plaintive elegie en long habits de deuil,*
> *Sçait, les cheveux epars, gemir ſur un cercueil:*
> *Elle peint des aimans la joye, & la triſteſſe;*
> *Flate, menace, irrite, appaiſe une maîtreſſe.*
>
> In mourning weeds ſad elegy appears,
> Her hair diſhevell'd, and her eyes in tears:
> Her theme, the lover's joys, but more his pains;
> By turns ſhe ſighs, ſooths, threatens, and complains.

The diction of elegy ought to be eaſy, perſpicuous, expreſſive of the manners, tender, and pathetic; not oppreſſed with ſentences, points, &c. No apoſtrophes are allowed; and the ſenſe ought to be generally cloſed in every diſtich, or two lines; at leaſt, in Latin compoſitions.

ELEMENTARY, ſomething that relates to the principles or elements of bodies. The elements of a body are alſo called the elementary principles thereof.

ELEMENT, a term uſed by philoſophers to denote the original component parts of bodies, or thoſe into which they are ultimately reſolveable. Some of the ancients repreſented the elements as corruptible, and ſome as incorruptible. Thoſe who maintained the incorruptibility of the elements, ſuppoſed them to be atoms, i. e. bodies which could not be divided, or broke into pieces. Of this opinion were Democritus, Epicurus, &c. Among thoſe who held the elements to be corruptible, ſome reckoned there was but one, and ſome that there were ſeveral elements. Heraclitus held fire, Anaximenes air, Thales Mileſius water, and Heſiod earth, to be the only element. The Peripatetics contended for four elements, fire, air, earth, and water. Some of theſe philoſophers conſidered only the ſenſible properties of bodies, ſuch as pellucidity and opacity, to be elements. Of this number Ariſtotle himſelf is ſaid to have been. For, conſidering the four principal qualities that fall under the ſenſe of touch, he made four elements: the firſt, cold and dry; the ſecond, cold and moiſt; the third, hot and moiſt; and the fourth, hot and dry. To give names to theſe elements, he inquired in what things theſe qualities were found chiefly to prevail. Accordingly, taking earth to be the coldeſt, and at the ſame time the drieſt, of all things, he called the firſt element earth. Water being the coldeſt and moiſteſt of all things, he called his ſecond element water; and imagining air to be the hotteſt and moiſteſt of all things, he called his third element air. Laſtly, fire being the hotteſt and drieſt of all things, he called his fourth element fire.

Succeeding philoſophers have differed greatly in their opinions; ſome adopting the Epicurean or atomical hypotheſis, and ſome the Ariſtotelian. It is, however, eaſy to ſee, that the queſtion concerning elements can never be ſolved. If we embrace the atomical ſyſtem, we muſt be conſcious that we know not what an atom is. We can have no idea of a body that doth not conſiſt of parts, and conſequently which cannot be made leſs than it is. If we adopt the notion of infinite diviſibility, or, which is much the ſame, of the Ariſtotelian qualities, we ſhall find ourſelves equally embarraſſed. Some have imagined that there are two diſtinct elements, which they call the celeſtial and terreſtrial matter. Both theſe they conſider as made up of atoms; but they ſuppoſe the atoms of the firſt to be active, and of the ſecond paſſive. It is difficult, however, to maintain this hypotheſis without allowing one kind of atoms to be animated. Certain it is, that we ſee one part of matter in many caſes acting upon, and giving motion to, another; but whether the matter which is paſſive in one caſe doth not become active in another, is a thing not eaſy to be determined. The utmoſt that can be ſaid upon the ſubject ſeems to be, that as long as matter is ſubject to our eye-ſight and other ſenſes, we can talk intelligibly about it; but when its parts become too ſmall to be obſerved by them, we are then totally in the dark.

ELEMENTS, in chymiſtry, are the principles, or component parts, of natural bodies, into which they are reſolveable by fire, &c. The effect of chymiſtry is, to analyſe or reſolve bodies into their elements. The chymical elements, are divided into active and paſſive. The chymiſts are ſomewhat divided as to their elements. The elements of foſſils are, 1. Mercury, as the baſe. 2. Sulphur, as the coagulator, or binder. 3. Salt. 4. Earth. The elements of metals are ſulphur and mercury alone; mercury as the baſe, or matter, and ſulphur as the binder or cement. The elements of foſſil ſalts are an acid ſpirit, and inſipid earth. The elements of earths are an oil, a little acid ſalt, and a calx. The elements of ſulphurs are an acid ſpirit, an oil, and an earthy or metallic matter. See Syſtem of CHYMISTRY, Part I. Sect. I. and II.

ELEMENTS are uſed, figuratively, for the grounds and principles of arts and ſciences. Thus we ſay, letters are the elements of ſpeech: he does not know the firſt elements of grammar. The elements of mathematics have been delivered by ſeveral authors in their courſes, ſyſtems, &c. The elements of Euclid are the firſt and beſt ſyſtem of geometry. We have abundance of editions, and comments on the fifteen books of Euclid's Elements.

ELEMENTS, in the higher geometry, are the infinitely ſmall parts, or differentials, of a right line, curve, ſurface, or ſolid. See Syſtem of GEOMETRY.

ELEMENTS, in aſtronomy, are thoſe principles deduced from aſtronomical obſervations and calculations, and thoſe fundamental numbers, which are employed in the conſtruction of tables of the planetary motions. Thus, the elements of the theory of the ſun, or rather of the earth, are his motion and eccentricity, and the motion of the aphelia. The elements of the theory of the moon are its mean motion, that of its node and apogee, its eccentricity, the inclination of its orbit to the plane of the ecliptic, &c. See Syſtem of ASTRONOMY, Sect. VII.

ELEPHANT, the Engliſh name of the genus elephas, in the Linnæan ſyſtem. For a deſcription of the different ſpecies of this genus, ſee ELEPHAS. For the claſſification, ſee MAMMALIA.

ELEPHANT *Beetle*, the Engliſh name of a ſpecies of the genus Scarabæus, in the Linnæan ſyſtem. For a deſcription of the different ſpecies of this genus, ſee SCARABÆUS. For the claſſification, ſee Syſtem of ENTOMOLOGY.

American ELEPHANT; an animal only known in a foſſile ſtate, and that but partially, from the teeth, ſome of the jaw bones, the thigh bones, and vertebræ, found with many others five or ſix feet beneath the ſurface on the banks of the Ohio. But theſe bones differ in ſeveral reſpects from thoſe of the elephant. As yet the living animal has evaded our ſearch. Mr. Pennant thinks it "more than probable, that it ſtill exiſts in ſome of thoſe remote parts of the vaſt new continent unpenetrated yet by Europeans. Providence maintains and continues every created ſpecies; and we have as much aſſurance that no race of animals will any more ceaſe while the earth remaineth, than *ſeed time and harveſt, cold and heat, ſummer and winter, day or night.*"

Knights of the ELEPHANT, an order of knighthood in Denmark, conferred upon none but perſons of the firſt quality and merit. It is alſo called the order of St. Mary. Its inſtitution is ſaid to have been owing to a gentleman among the Daniſh croiſes having killed an elephant, in an expedition againſt the Saracens, in 1184; in memory of which, king Canutus inſtituted this order, the badge of which is a towered elephant, with an image of the holy virgin encircled with rays, and hung on a watered ſky-coloured ribbon, like the George in England.

ELEPHANTIASIS, in medicine, a kind of leproſy, called alſo *lepra arabum*, in contradiſtinction to the *lepra græcorum*, which is another diſeaſe. The elephantiaſis is thus denominated, becauſe thoſe ſeized therewith have their arms and legs big, ſwollen, and tumorous; the ſkin bloated, yet rough to the touch, and all wrinkled and rugoſe like the ſkin of an elephant. The elephantiaſis is a diſeaſe unknown in our parts of the world, at leaſt in theſe days.

ELEPHANTINE, ſomething that relates to or partakes of the qualities of elephants. The term is chiefly applied to certain books of the ancient Romans, wherein were recorded the tranſactions of the emperors, and the proceedings, acts, &c. of the ſenate. They are ſuppoſed to have been ſo called, as being made of ivory; though ſome will have them to have been written on the inteſtines of elephants.

ELEPHAS, or the ELEPHANT, a genus of quadrupeds belonging to the order of bruta. The characters are theſe: the elephant has no ſore-teeth in either jaw, and the dog-teeth are very long: the proboſcis, or trunk, is long, and capable of laying hold of any thing; and the body is ſomewhat naked.

The elephant is the largeſt of all land-animals. From the front to the origin of the tail he is generally about 16 feet long, from the end of the trunk 25 feet, and about 14 feet high. The circumference of the neck is 17 feet, and the circumference of the body at the groſſeſt part 25 feet 10 inches; the tail is about 6 feet long, and 2½ in circumference. The circumference of the legs is about 6 feet. The trunk is, properly ſpeaking, the noſe extended, and terminated by a couple of noſtrils. But, beſides ſerving as an organ of ſmell, the trunk performs all the functions of a ſtrong and dexterous arm. The trunk of an elephant is about 8 feet long, 5½ feet in circumference near the mouth, and one foot and a half near the extremity: it is a pipe of an irregular conical figure, and widened at the end.

The elephant can move the trunk in all directions; he can extend or ſhorten it at pleaſure, without altering the diameters of the two canals within. At the extremity of the trunk there is a concave protuberance, in the bottom of which are the two paſſages of the noſtrils. The inferior part of the protuberance is thicker than the ſides, and the ſuperior part is ſtretched out like a finger about five inches long; which, together with the edges of the whole extremity of the trunk, takes on different figures according to the neceſſities of the animal. It is by this organ that the animal lays hold of food, or other ſubſtances; which he manages with as much dexterity as a man does his hand, taking up grains of corn, or the ſmalleſt piles of graſs, and conveying them to his mouth. When he drinks, he thruſts his trunk into the water, and fills it by drawing in his breath, and exhauſting the air: when the trunk is thus filled with water, he can either throw it out to a great diſtance, or drink it by putting the end of the trunk in his mouth. The two large tuſks, which ſome call the horns of the elephant, are of a yellowiſh colour, and extremely hard. The bony ſubſtance of which they are compoſed is known by the name of ivory, and much uſed in different branches of manufacture. The female has two dugs, one on each ſide of the breaſt. The parts of generation are ſmall in proportion to thoſe of other animals. The penis reſembles that of a horſe. The female organ is ſituated near the middle of the belly, more than two feet diſtant from the uſual ſituation in other quadrupeds: when they copulate, the female lies down on her back.

Elephants, even in a ſavage ſtate, are peaceable and gentle creatures. They never uſe their weapons but in defence of themſelves or companions. Their ſocial diſpoſitions are ſo ſtrong, that they are ſeldom found alone, but march always in large troops: the oldeſt and moſt experienced lead the van; the younger, or lame ones, keep in the middle; and thoſe of a ſecond rate, as to age, walk in the rear. The females carry their young on their tuſks, embracing them at the ſame time with their trunk. They ſeldom march in this regular order but when they reckon the journey dangerous, ſuch as an expedition to cultivated lands, where they expect to meet with reſiſtance. On other occaſions they are leſs cautious; ſome of them falling behind or ſeparating from the reſt, but ſeldom ſo far as to be without the reach of aſſiſtance by alarming and aſſembling their companions. It is only theſe wanderers that the hunters dare attack: for it would require a whole army to aſſail a troop of them; and even an army would be unable to conquer them without loſing a number of lives. It is dangerous to offer them the leaſt injury: for they run ſtraight upon the offender; and, although the weight of their body be great, their ſteps are ſo large, that they eaſily outrun the ſwifteſt man, whom they either pierce with their tuſks, or ſeize with their trunk, dart him in the air like a ſtone, and then trample him under their feet. But they never attack any perſon, unleſs when provoked. However, as they are extremely ſenſible and delicate with regard to injuries, it is always prudent to keep out of their way. Travellers who frequent theſe countries kindle large fires, and beat drums during the night, in order to prevent their approach. After being once attacked by men, or falling into any ambuſh, they are ſaid never to forget the injury, but ſearch for every opportunity of getting revenge. As they are endowed perhaps with a more exquiſite ſenſation of ſmell than any other animal, owing to the great extent of their noſe, they can ſcent a man at a very great diſtance, and trace him by his footſteps.

The ordinary food of elephants is roots, herbs, leaves, the tender branches of trees, fruits, and grains: but they abhor fleſh or fiſh. When any of them diſcovers a fine paſture, he immediately calls and invites his companions to come and eat with him. As they devour a large quantity of food in a ſhort time, they are always ſhifting their paſture; when they meet with cultivated grounds, they make a prodigious deſolation and deſtroy more plants by their feet than they uſe for nouriſhment; which laſt is very conſiderable, amounting to 150 pounds of herbage every day: by this means, as they conſtantly graze in large troops, they lay waſte whole fields in an hour. The Indians and negroes employ every art to prevent them from viſiting their cultivated lands, making great noiſes, and burning large fires round their fields. However, theſe precautions are not always ſufficient to prevent the elephants from viſiting them. They chaſe away the domeſtic animals, put the men to flight, and ſometimes even throw down their limber huts. Elephants are hardly ſuſceptible of fear; the only things which can ſurpriſe them, or ſtop their courſe, are artificial fires, ſuch as ſquibs, crackers, &c. the effects of which are ſo ſudden and ſo quickly repeated, that the elephants frequently turn back; and when one runs, all the reſt inſtantly follow his example.

Although the ſocial diſpoſition in the elephant be exceeding ſtrong; yet whenever the females come in ſeaſon, it immediately gives place to the ſtronger and more intereſting paſſion of love. They obſerve the greateſt delicacy in their amours, abhorring nothing ſo much as to be ſeen by their companions. The troop divide themſelves into couples, ſteal off into the moſt ſecret places of the foreſt, and then give way to all the impulſes of nature, which are lively and laſting in proportion to the long period of abſtinence; for the female goes with young two years, and it is only once in three years that the ſeaſon of love returns. They bring forth but one at a time; which as ſoon as it comes into the world, is as large as a wild boar, and is furniſhed with teeth; however, the large tuſks do not make their appearance till ſome time after, and at the age of ſix months they are ſeveral inches long. Elephants of this age are as large as an ox, when in a natural ſtate. But it is incredible how they degenerate when inſlaved and under the management of men. Their diſguſt and chagrin for the loſs of liberty ſeems never to depart from their minds. In this ſtate, though they feel, at the proper ſeaſons, the ſtrongeſt deſires for the ſex, no art can allure them to copulate: but the natural paſſion, reſtrained by an exceſs of modeſty, burſts out into ſuch violent fits of fury and reſentment, that the ſtrongeſt chains are hardly ſufficient to command them. This is a ſtriking difference betwixt the elephant and moſt other tamed animals. It is only the individual that we can enſlave; the ſpecies, in ſpite of all our endeavours, ſtill retain their original freedom and independence.

The manner of taking and taming elephants, therefore merits our attention. In foreſts and ſuch places as are frequented by elephants, the Indians chooſe a ſpot and incloſe it with ſtrong palliſades. The guide then makes the female proceed towards the artificial incloſure, repeating her cries from time to time as ſhe goes along. She enters into the incloſure, the male follows her, and the Indians immediately ſhut the port behind him. He no ſooner diſcovers the hunters, and that he is incloſed, than his paſſion for the ſex is converted into rage and fury. The hunters entangle him with ſtrong ropes; they fetter his legs and trunk; they bring two or three tame elephants in order to pacify and reconcile him to his condition. In a word, they reduce him to obedience in a few days, by a proper application of torture and careſſes. There are many other methods of catching elephants. Inſtead of making large incloſures with palliſades, like the kings of Siam, and other monarchs, the poor Indians content themſelves with a very ſimple apparatus: they dig deep pits in the roads frequented by elephants, covering them over with branches of trees, turf, &c. When an elephant falls into one of theſe pits, he is unable to get out again. The elephant, when tamed, is the moſt friendly and obedient of all animals; he is entirely attached to the perſon who feeds and takes care of him. In a ſhort time he underſtands ſigns, and the ſound of his maſter's voice. He diſtinguiſhes the language of paſſion, of command, of ſatisfaction; and acts accordingly. He receives his orders with attention, and executes them with prudence and alacrity, but without precipitation. He eaſily learns to bow his knees and lower his body, for the convenience of thoſe who mount him. He careſſes his friends with his trunk. He lifts burdens with his trunk, and aſſiſts thoſe who are loading him in laying them on his back. He delights in ſhining harneſs and trappings. When yoked in a cart or waggon, he pulls equally and cheerfully, unleſs he be abuſed by injudicious chaſtiſements. His guide is generally mounted on his neck, with a ſmall rod of iron ſharp at the point in his hand; he directs his motion by pricking him on the ears and head; but, for the moſt part, a word is ſufficient.

A tame elephant will do more labour than ſix horſes: but then he requires a proportional quantity of food. They are the principal beaſts of burden in many parts of Africa and the Eaſt Indies. They carry ſacks and bundles of all kinds on their neck, back, and tuſks. They never loſe or damage any thing committed to their care; they will ſtand on the edge of a river, take bundles off their necks and tuſks, lay them carefully in a boat wherever they are deſired, and try with their trunk whether they are properly ſituated; if they be loaded with caſks, they go in queſt of ſtones to prop them and prevent them from rolling. The elephant is not only the moſt tractable, but the moſt intelligent, of animals; ſenſible of benefits, reſentful of injuries, and endowed even with a ſenſe of glory. In Delli, an elephant paſſing along the ſtreets, put his trunk into a taylor's ſhop, where ſeveral people were at work; one of them pricked the end with his needle: the beaſt paſſed on: but in the next dirty puddle filled his trunk with water, returned to the ſhop, and ſpurting every drop among the people who had offended him, ſpoilt their work. At the Cape of Good-Hope, it is cuſtomary to kill thoſe animals, for the ſake of their teeth, by the chace. Three horſemen, well-mounted and armed with lances, attack the elephant alternately, each relieving the other as they ſee their companion preſſed, till the beaſt is ſubdued. Three Dutchmen (brothers), who had made large fortunes by this buſineſs, determined to retire to Europe, and enjoy the fruits of their labours; but reſolved, before they went, to have a laſt chaſe by way of amuſement; they met with their game, and began the attack in the uſual manner; but unfortunately one of their horſes fell down and flung it's rider; the enraged animal inſtantly ſeized the unhappy man with its trunk, flung him up to a vaſt height in the air, and received him on one of it's tuſks; then turning towards the two other brethren, as if it were with an aſpect of revenge and inſult, held out to them the impaled wretch wreathing on the bloody tooth.

From the earlieſt accounts in hiſtory, the eaſtern nations have employed elephants in war; Alexander the Great was the firſt European who ever mounted an elephant. He carried a number of them into Greece, which Pyrrhus employed ſome years after againſt the Romans at the battle of Tarentum. Both the Greeks and Romans ſoon learnt to get the better of theſe monſtrous animals: they opened their ranks and allowed them to paſs through; neither did they attempt to hurt them, but threw darts, &c. at their guides. Now that fire arms are the principal inſtruments of war, elephants, who are terrified at the noiſe and flame, inſtead of being uſeful, would only tend to embarraſs and confuſe an army. However, in Cochin and other parts of Malabar, as alſo in Tonquin, Siam, and Pegu, where fire arms are little underſtood, they are ſtill uſed in battle. The guide ſits aſtride upon the neck, and the combatants ſit or ſtand upon the other parts of the body.

When the elephant is properly managed, he lives very long even in a ſtate of ſlavery and labour. That ſome have lived in this ſtate 130 years, is pretty well authenticated. In a natural ſtate, they often exceed 200 years, and propagate their ſpecies till they are 120: it is 30 years before they come to their full growth. The elephant inhabits India, and ſome of its greater iſlands, Cochin China, and ſome of the provinces of China. It abounds in the ſouthern parts of Africa, from the river Senegal to the Cape; and from thence as high as Ethiopia on the other ſide. They are found in the greateſt numbers in the interior parts, where there are vaſt foreſts, near the ſides of rivers. They are not at preſent domeſticated in Africa, but only in the more civilized parts of Aſia. They are much more numerous in Africa. In ſome parts they ſwarm ſo, that the Negroes are obliged to make their habitations under ground for fear of them. They are killed and eaten by the natives, and the trunk is ſaid to be a delicious morſel. All the teeth are brought from Africa: they are frequently picked up in the woods; ſo that it is uncertain whether they are ſhed teeth, or thoſe of dead animals. The African teeth which come from Moſambique, are 10 feet long; thoſe of Malabar only three or four; the largeſt in Aſia are thoſe of Cochin China, which even exceed the ſize of the elephants of Moſambique. The ſkin is thick, and, when dreſſed, proof againſt a muſket ball. The fleſh, the gall, the ſkin, and the bones, are ſaid to be uſed medicinally by the Chineſe.

ELEVATION, the altitude or height of any thing. See ALTITUDE. The word is formed from *elevare*, to raiſe or lift up.

Elevation, in architecture, denotes a draught or deſcription of the principal face or ſide of a building called alſo its upright or orthography.

Elevation, in the Romiſh religion, is applied to that part of the maſs wherein the prieſt hoiſts or raiſes the hoſt, with the cup above his head, for the people to adore it, after having firſt conſecrated and adored it himſelf.

ELEVATOR, **Elevatorium**, in ſurgery, an inſtrument uſed to raiſe up bones, as thoſe in fractures of the ſkull, when beaten or cruſhed in with blows, or the like. See Syſtem of SURGERY.

Elevator, in anatomy, is a name common to ſeveral muſcles, which do the office of raiſing or lifting up the parts they belong to, of equal import with the attollens and levator. See Syſtem of ANATOMY, Part III. Sect. IX.

ELEUSINIA, in antiquity, the myſteries of the goddeſs Ceres, or the religious ceremonies performed to her honour; thus called from Eleuſis, a maratime town of the Athenians, wherein was a temple of that goddeſs, famous for the celebration of theſe myſteries. See CEREALIA.

ELIGIBILITY, in the Romiſh canon law. A bull of eligibility is a bull granted by the pope, to certain perſons, to qualify them to be choſen, or inveſted with an office, or dignity, whereof they were before incapable, by reaſon of want of age, birth, or the like. The word is formed of the Latin *eligere, to chuſe*; whence the word *eligibilitas*, &c. In ſeveral churches in Germany, a perſon, who is not of the chapter, cannot be elected biſhop, without a bull of eligibility.

ELIQUATION, in chymiſtry, an operation by which a more fuſible ſubſtance is ſeparated from one that is leſs ſo, by means of a heat ſufficiently intenſe to melt the former, but not the latter. Thus an allay of copper and lead may be ſeparated by a heat capable of melting the latter, but not the former.

ELISION, in grammar, the cutting off, or ſuppreſſing a vowel at the end of a word, for the ſake of ſound or meaſure. Eliſions, excepting in poetry, are but little known in Engliſh; in Latin, French, &c. they are frequent, and conſiſt moſtly in ſuppreſſions of the final *a*, *e*, and *i*: as in *Phillida amo ante alias. Si ad vitulum ſpectes*, &c. In wrigting, eliſions are often marked by an apoſtraphe; as *egon' quem quæram?* for *egone*. *Emin' ego te?* for *emine*. *Veniſtin'* for *veniſtine*, &c. *Cett' eſperance*, for *cette*; *l'homme*, for *le homme*. In the pronounciation we make frequent eliſions, but do not mark them in writing: thus we write *riſque it*, but pronounce *riſq' it*. So the French pronounce *un' ame*, but write *une ame*. In effect, they never mark any eliſions but at the end of the monoſyllables *je*, *ne*, *le*, *te*, *ce*, *que*, and *la*. They never elide in the *o*, nor *u*, nor *i*, but in the conjunction *ſi*, before *il*; nor *a*, but in *la*. In poetry, the ſyllable where there is a vowel elided, is never reckoned; and great care is taken to avoid the claſhing of ſyllables where there is no eliſion, this making what they call a *hiatus* or *chaſm*.

ELIXATION, in pharmacy, &c. the infuſing, ſeething, or boiling of any medicine in a proper liquor, gently, and for a conſiderable time; amounting to what, in the dreſſiing of meat, we call ſtewing. The word is formed from the Latin *lixare, to boil*, or *boil in water*.

ELIXIR, in medicine, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir ſeems to be this, that a tincture is drawn from one ingredient, ſometimes with an addition of another to open it, and to diſpoſe it to yield to the menſtruum; whereas an elixir is a tincture extracted from ſeveral ingredients at the ſame time.

ELK is a wild beaſt, found in the foreſts of Muſcovy, Sweden, and Pruſſia; but more abundantly in Canada, and moſt parts of North America. It is about the ſize and figure of a mule, only its ſnout bigger, its tail ſhorter, its feet cloven; and that it bears a large ramage, or horn, like that of a deer. That anatomized, in the Royal Academy of Sciences, was five feet ſeven inches long. Its hair is brown, about the length of that of a goat; and being very elaſtic, is uſed for matraſſes; its ears nine inches long, and four broad; and its tail not above two inches; its neck ſhort and thick; its ſkin ſtrong and hard, though thin; ſo that, according to Linnæus, it will turn a muſket-ball: its fleſh very delicate, eſpecially that of the female.

The hunting of the elk, is one of the principal and moſt agreeable employments of the ſavages of Canada, Acadia, &c. They chooſe a time when the ſnow is on the ground, in which the beaſt is apt to ſink and ſtick. When they have killed enough with their fire arms to feaſt for ſeveral days, they flay them, and ſend the ſkins to the manufacturers, who dreſs them in oil, like the buffalo ſkin.

ELL, *ulna*, a meaſure, which obtains, under different denominations, in moſt countries. The ell is the ſtandard, or meaſure, whereby cloths, ſtuffs, linens, ſilks, &c. are uſually meaſured, or eſtimated, anſwering, in good meaſure, to the yard of England, the canna of Italy, the vara of Spain, the palm of Sicily, &c.

ELLIPSIS, in geometry, one of the conic ſections, commonly called an oval. The word is formed from the Greek, ελλειψις, *deficiency*, a denomination which the ancient Greek geometricians gave this figure, becauſe among other properties this is one, that the ſquares of the ordinates are leſs than, or defective of, the rectangles under the parameters and abſciſſes. See Syſtem of GEOMETRY.

Ellipsis, in grammar and rhetoric, is a verbal figure, or a figure of ſyntax, wherein ſomething is ſuppreſſed, or left out, in a diſcourſe, and ſuppoſed or underſtood; or, it is a defect or omiſſion of ſome part of a ſentence, which muſt be ſupplied in order to render the conſtruction complete.

ELLIPTIC, or Elliptical, ſomething that belongs to an ellipſis.

Elliptic compaſſes, an inſtrument made uſually in braſs, for the drawing any ellipſis or oval, by one revolution of an index.

Elliptic *Dial*, is an inſtrument uſually of braſs, with a joint or fold together, and the gnomon to fall flat, for the ſake of the pocket. By it are found the meridian, hour of the day, riſing and ſetting of the ſun, &c. See Dial.

ELM, in botany, the Engliſh name of the genus ulmus. See Ulmus.

ELOCUTION. See Treatiſe on the Art of Oratory.

ELOGY, a praiſe or panegyric beſtowed on any perſon or thing, in conſideration of its merit. The beauty of elogy conſiſts in an expreſſive brevity. Eulogiums ſhould not have ſo much as one epithet, properly ſo called, nor two words ſynonymous: they ſhould ſtrictly adhere to truth; for extravagant and improbable elogies rather leſſen the character of the perſon or thing they would extol.

ELOHI, Eloi, or Elohim, in Scripture, one of the names of God. But it is to be obſerved, that angels, princes, great men, judges, and even falſe gods, are ſometimes called by this name.

ELONGATION, in aſtronomy, the digreſſion, or receſs of a planet from the ſun, with reſpect to an eye placed on our earth. See Syſtem of Astronomy, Sect. IX.

ELOPEMENT, in law, is when a married woman, of her own accord, departs from her huſband, and dwells with an adulterer; for which, without voluntary reconcilement to the huſband, ſhe ſhall loſe her dowry; nor ſhall the huſband, in ſuch caſe, be compelled to allow her any alimony. The word is formed from the Belgic, *Ee, matrimony*, and *loopen, to run away*. However, mere advertiſing a wife in the gazette, or other public papers, is not a legal notice to perſons in general not to truſt her; though a perſonal notice given by the huſband to particular perſons is ſaid to be good. An action lies, and large damages are uſually given, againſt a perſon for carrying away, and detaining another man's wife.

ELOQUENCE, the art of ſpeaking or writing well; ſo as to move and perſuade. See Treatiſe on the Art of Oratory.

ELUDING, the act of evading, or rendering a thing vain, and of no effect; a dextrous getting clear, or eſcaping out of an affair, difficulty, embarraſſment, or the like. We ſay, to elude a propoſition, &c.

ELUTRIATION, in metallurgy, is the ſeparating the lighter matters from the mixed ores of metal, by means of great quantities of fair water. Solid bodies not diſſoluble in water, are, by this operation, ſeparated from each other by water very well ſtirred, ſo that the lighter and finer parts are carried away with the water, and the heavier and more ſolid remain at the bottom of the veſſels.

ELYSIUM, Ελυσιος, in the ancient theology, or rather mythology, a place in the inferi, i. e, in the lower world; furniſhed with fields, meads, agreeable woods, groves, ſhades, rivers, &c. whither the ſouls of good people were ſuppoſed to go after this life. Orpheus, Hercules, and Æneas, are ſuppoſed to have deſcended into elyſium, in their life time, and to have returned again. Virgil, lib. vi. ver. 638, &c. Tibullus, lib. i. eleg. 3. gives us fine deſcriptions of the elyſian fields. Virgil oppoſes elyſium to tartara; which was the place where the wicked underwent their puniſhment.

ELYTROIDES, Ελυτροειδης, in anatomy, one of the proper coats, or tunics of the teſticles. The word is formed of the Greek ελυτρον, *vagina*, a *ſheath*, and ειδος, *form*.

EMANATION, the act of flowing, or proceeding, from ſome ſource or origin. Such is the emanation of light from the ſun; or that effluvia from odorous, &c. bodies; of wiſdom from God, &c. The word is formed of the Latin *e, out of*, and *manare, to flow* or *ſtream*.

Emanation is alſo uſed for the thing that proceeds, as well as the act of proceeding. The power given a judge is an emanation from the regal power; the reaſonable ſoul is an emanation from the divinity.

EMANCIPATION, in the Roman law, the ſetting free a ſon from the ſubjection of his father; ſo that whatever moveables he acquires belong in property to him, and not to his father, as before emancipation. Emancipation puts the ſon in a capacity of managing his own affairs, and of marrying without his father's conſent, though a minor. Emancipation differs from manumiſſion, as the latter was the act of a maſter in favour of a ſlave, whereas the former was that of a father in favour of his ſon.

EMASCULATION, the act of taking from a male thoſe parts which are characteriſtic of his ſex. See Castration.

EMAUX *de l' Eſcu*, in heraldry, the metals and colours of a ſhield, or ſcutcheon.

EMBALMING, is the opening a dead body, taking out the inteſtines, and filling the place with odoriferous and deſiccative drugs and ſpices, to prevent its putrifying. The Egyptians excelled all other nations in the art of preſerving bodies from corruption; for ſome that they have embalmed upwards of 2000 years ago, remain whole to this day, and are often brought into other countries as great curioſities. Their manner of embalming was thus: they ſcooped the brains with an iron ſcoop, out at the noſtrils, and threw in medicaments to fill up the vacuum: they alſo took out the entrails, and, having filled the body with myrrh, caſſia, and other ſpices, except frankincenſe, proper to dry up the humours, they pickled it in nitre, where it lay ſoaking for 70 days. The body was then wrapped up in bandages of fine linen, and gums, to make it ſtick like glue; and ſo was delivered to the kindred of the deceaſed, entire in all its features, the very hairs of the eyelids being preſerved. They uſed to keep the bodies of their anceſtors, thus embalmed, in little houſes magnificently adorned, and took great pleaſure in beholding them, alive as it were, without any change in their ſize, features, or complexion. The Egyptians alſo embalmed birds, &c. The prices for embalming were different; the higheſt was a talent, the next 29 minæ, and ſo decreaſing to a very ſmall matter: but they who had not wherewithal to anſwer this expence, contented themſelves with infuſing, by means of a ſyringe, through the fundament, a certain liquor extracted from the cedar; and, leaving it there, wrapped up the body in ſalt of nitre: the oil thus preyed upon the inteſtines, ſo that when they took it out, the inteſtines came away with it, dried, and not in the leaſt putrified: the body being encloſed in nitre, grew dry, and nothing remained beſides the ſkull glued upon the bones.

The method of embalming uſed by the modern Egyptians, according to Maillet, is to waſh the body ſeveral times with roſe-water, which, he elſewhere obſerves, is more fragrant in that country than with us; they afterwards perfume it with incenſe, aloes, and a quantity of other odours, of which they are by no means ſparing; and then they bury the body in a winding ſheet, made partly of ſilk and partly of cotton, and moiſtened, as is ſuppoſed, with ſome ſweet ſcented water or liquid perfume, though Maillet uſes only the term moiſtened; this they cover with another cloth of unmixed cotton, to which they add one of the richeſt ſuits of clothes of the deceaſed. The expence, he ſays, on theſe occaſions, is very great, though nothing like what the genuine embalming coſt in former times.

EMBARGO, in commerce, an arreſt on ſhips or merchandiſe, by public authority; or a prohibition of ſtate, commonly on foreign ſhips, in time of war, to prevent their going out port, ſometimes to prevent their coming in, and ſometimes both, for a limited time. The king may lay embargoes on ſhips, or employ thoſe of his ſubjects, in time of danger, for the ſervice and defence of the nation: but they muſt not be for the private advantage of a particular trader, or company; and therefore a warrant to ſtay a ſingle ſhip is no legal embargo. No inference can be made from embargoes which are only in war time; and are a prohibition by advice of council, and not at proſecution of parties. If goods be laden on board, and after an embargo or reſtraint from the prince or ſtate comes forth, and then the maſter of the ſhip breaks ground, or endeavours to ſail, if any damage accrues, he muſt be reſponſible for the ſame; the reaſon is, becauſe his freight is due, and muſt be paid, even though the goods be ſeized as contraband.

EMBASSY, *legatio*, a miſſion from one ſovereign prince, or ſtate, to another, of ſome able experienced perſon, to negotiate ſome affair in quality of ambaſſador.

EMBATTLED, a term in heraldry, when the outer line of any ordinary is notched in a manner repreſenting the battlements of a wall or caſtle.

EMBER *Weeks*, are thoſe wherein the ember or embering days fall. In the laws of king Alfred, and thoſe of Canute, thoſe days are called *ymbren*, that is, *circular days*, from whence the word was probably corrupted into *ember days*. By the canoniſts they are called *quatuor anni tempora*, the four cardinal ſeaſons, on which the circle of the year turns; and hence Henſhaw takes the word to have been formed, viz. by corruption, from *temper*, or *tempora*. The ember days are the Wedneſday, Friday, and Saturday, after Quadrageſima Sunday, or the firſt Sunday in Lent, after Whitſunday, after Holyrood day in September, and after St. Lucy's day in December; which four times anſwer well enough to the four quarters of the year, ſpring, ſummer, autumn, and winter. Theſe ember weeks are now chiefly taken notice of on account of the ordination of prieſts and deacons; becauſe the canon appoints the Sundays next ſucceeding the ember weeks for the ſolemn times of ordination; though the biſhops, if they pleaſe, may ordain on any Sunday or holiday.

EMBERIZA, or Bunting, in ornithology, the 70th genus of birds, belonging to the ſixth order, according to Linnæus. Latham, in his improved arrangement, makes it the 35th genus, and of the order of Paſſerine.

EMBLEM, Εμβλημα, a kind of painted ænigma, which, repreſenting ſome obvious hiſtory, with reflections underneath, inſtructs us in ſome moral truth, or other matter of knowledge. The word is pure Greek, formed of the verb εμβαλλειν, *to caſt in, to inſert*. The emblem is ſomewhat plainer, and more obvious, than the ænigma. Gale defines emblem an ingenious picture, repreſenting one thing to the eye, and another to the underſtanding. With us, emblem ordinarily ſignifies no more than a painting, *baſſo relievo*, or other repreſentation, intended to hold forth ſome moral or political inſtruction. What diſtinguiſhes an emblem from a device is, that the words of an emblem have a full, complete ſenſe of themſelves; nay, all the ſenſe and ſignification which they have together with the figure. But there is yet a farther difference between emblem and device; for a device is a ſymbol appropriated to ſome particular perſon, or that expreſſes ſomething which concerns him particularly; whereas an emblem is a ſymbol that regards all the world alike. Theſe differences will be more apparent from comparing the emblem above quoted with the device of a candle lighted; and the words *juvando conſumor, I waſte myſelf in doing good.* According to lord Bacon, emblems are of uſe in the art of memory, as ſenſible objects ſtrike the mind ſtronger than what is intellectual. Thus, it is eaſier to retain the image of a ſportſman hunting a hare, of an apothecary ranging his boxes, an orator making a ſpeech, a boy repeating verſes, or a player acting his part, than the correſponding notions of invention, diſpoſition, elocution, memory, and action. Works abr. vol. i. p. 136. vol. ii. p. 475. and vol. iii. p. 106.

EMBOSSING, or Imbossing, the act of forming, or faſhioning works in relievo, whether they be caſt, or moulded, or cut with the chiſſel, &c. Emboſſing is one great part of ſculpture; being that which has to do with figures raiſed, or prominent from the plane, or ground; the other part, which makes figures, &c. that are indented, or cut in below the ground, is called engraving. See Engraving.

EMBROCATION, Εμβροχη, formed from βρεχω, *irrigo, I ſprinkle*, or *moiſten*, in pharmacy, denotes the application of remedies, as oils, ſpirits, decoctions, and other liquids, by ſprinkling, or even rubbing them on the part affected: this is alſo called irrigation. Embrocations are only a kind of lotions; they are uſed to remove obſtructions, and to relieve pains, numbneſs, and palſies. The pumping uſed in natural baths is properly an embrocation.

EMBROIDERY, a work in gold, or ſilver, or ſilk thread, wrought by the needle upon cloth, ſtuffs, or muſlin, into various figures. In embroidering ſtuffs, the work is performed in a kind of loom; becauſe the more the piece is ſtretched, the eaſier it is worked. As to muſlin, they ſpread it upon a pattern ready deſigned; and ſometimes, before it is ſtretched upon the pattern, it is ſtarched, to make it more eaſy to handle. Embroidery on the loom is leſs tedious than the other, in which, while they work flowers, all the threads of the muſlin, both lengthwiſe and breadthwiſe, muſt be continually counted; but, on the other hand, this laſt is much richer in points, and ſuſceptible of greater variety. Cloths too much milled are ſcarce ſuſceptible of this ornament, and in effect we ſeldom ſee them embroidered. The thinneſt muſlins are left for this purpoſe; and they are embroidered to the greateſt perfection in Saxony: in other parts of Europe, however, they embroider very prettily, and eſpecially in France.

There are ſeveral kinds of embroidery: as, 1. Embroidery on the ſtamp; where the figures are raiſed and rounded, having cotton or parchment put under them to ſupport them. 2. Low embroidery; where the gold and ſilver lie low upon the ſketch, and are ſtitched with ſilk of the ſame colour. 3. Guimped embroidery: this is performed either in gold or ſilver; they firſt make a ſketch upon the cloth, then put on cut vellum, and afterwards ſow on the gold and ſilver with ſilk thread: in this kind of embroidery they often put gold and ſilver cord, tinſel, and ſpangles. 4. Embroidery on both ſides; that which appears on both ſides of the ſtuff. 5. Plain embroidery; where the figures are flat and even, without cords, ſpangles, or other ornaments.

By ſtat. 22. Geo. II. c. 36. no foreign embroidery, or gold and ſilver brocade, ſhall be imported, upon pain of being forfeited and burnt, and penalty of 100l. for each piece. No perſon ſhall ſell, or expoſe to ſale, any foreign embroidery, gold or ſilver thread, lace, fringe, brocade, or make up the ſame into any garment, on pain of having it forfeited and burnt, and penalty of 100l. All ſuch embroidery, &c. ſhall be ſeized and burnt; and the mercer, &c. in whoſe cuſtody it was found, ſhall forfeit 100l.

EMBRYO, in phyſiology, the firſt rudiments of an animal in the womb, before the ſeveral members are diſtinctly formed; after which period it is denominated a fetus. See Generation, and Fetus.

Embryo is alſo uſed by naturaliſts to expreſs the grain, or ſeed of a plant; ſometimes the germ, or firſt ſprout appearing out of the ſeed; becauſe the whole future plant is ſuppoſed to be contained therein. Juſt as the whole chick is ſuppoſed contained in the cicatricula, or treddle of an egg.

Embryo *Worms*. It is a matter of no ſmall curioſity, to obſerve the arrangement of the multitudes of the embryo-worms, as they are lodged in the bodies of the viviparous two winged flies. An accurate diſſection of one of theſe little animals, ſhews very plainly the parts where the embryo-worms are incloſed. This diſſection is eaſily made with a pair of fine pointed ſciſſars, taking off the whole upper ſhell of the body from the lower; and that part which covers the belly may be turned back upon the corcelet, without diſturbing the internal parts by the operation; and the form and arrangement of the parts which contain the embryo-worms in theſe, will be found very different from that of thoſe which contain the eggs in the common flies. Baker on the Microſcope, p. 115. 416. 417. 428. 430.

EMERALD, a genus of precious ſtone, very green and tranſparent; and, as to hardneſs, the next after the ruby. The word is formed from the French *eſmeraude*, and that from the Latin *ſmaragdus*, which ſignifies the ſame. Others derive it from the Italian *ſmeraldo*, or the Arabic *zomorrad*. Our jewellers diſtinguiſh emeralds into two kinds; the oriental, and occidental. The emeralds of the Eaſt Indies are evidently finer than thoſe of any other part of the world; but our jewellers, ſeldom meeting with theſe, call the American emeralds the oriental; and uſually ſell chryſtal, accidentally tinged with green, under the name of the occidental emerald; theſe being alſo the moſt common, there has grown an opinion among the lapidaries, that the emerald is no harder than the cryſtal; becauſe what they take to be emeralds, are in general only cryſtals. The genuine emerald, in its moſt perfect ſtate, is perhaps the moſt beautiful of all the gems; it is found of various ſizes, but uſually ſmall; a great number of them are met with of about the ſixteenth part of an inch in diameter, and they are found from this to the ſize of a walnut. The emerald is of different figures like the diamond and many of the other gems; being ſometimes found in a roundiſh or pebble-like form, but much more frequently in a columnar one, reſembling common cryſtal: the pebble-emeralds are always the hardeſt and brighteſt, but are ſeldom found exceeding the ſize of a pea; the cryſtalliform ones grow ſeveral together, and are often larger; the pebble-kind are found looſe in the earths of mountains, and ſands of rivers: the columnar are found uſually bedded in, or adhering to, a white, opake, and coarſe cryſtalline maſs, and ſometimes to the jaſper or the praſius. The oriental emerald is of the hardneſs of the ſapphire and ruby, and is ſecond only to the diamond in luſtre and brightneſs: the American is of the hardneſs of the garnet: and the European ſomewhat ſofter than that, yet conſiderably harder than cryſtal; it loſes its colour in the fire, and becomes undiſtinguiſhable from the white ſapphire. The oriental emeralds are very ſcarce, and at preſent found only in the kingdom of Cambay. Very few of them have of late been imported into Europe, inſomuch that it has been ſuppoſed there were no oriental emeralds; but, lately, ſome few have been brought from Cambay into Italy, that greatly excel the American ones. The American, being what our jewellers call *oriental emeralds*, are found principally about Peru; and the European are principally from Sileſia.

Emerald, or Emeraud, in heraldry, is uſed in lieu of vert, or green, in blazoning the arms of dukes, earls, &c.

EMERSION, in phyſics, the riſing of any ſolid above the ſurface of a fluid ſpecifically heavier than itſelf, into which it had been violently immerged, or thurſt.

Emersion, in aſtronomy, is when the ſun, moon, or other planet, begins to re-appear, after its having been eclipſed, or hid by the interpoſition of the moon, earth, or other body: The difference of longitude is ſometimes found by obſerving the immerſions and emerſions of the firſt of Jupiter's ſatellites. See Syſtem of Astronomy, Sect. VIII.

EMERY, a ſort of metallic ſtone, found in ſeveral mines of metals; but chiefly in thoſe of iron, being properly an iron ore. We uſually diſtinguiſh three kinds of emery; the Spaniſh, red, and commom emery. The firſt is found in the gold mines of Peru, and other provinces of the Spaniſh America; it is judged a kind of ore of that rich metal; being ſtreaked with little veins, and ſpecks of gold. The red emery is found in copper mines; the little we have of it comes from Sweden and Denmark. The common emery is taken out of iron mines; and is almoſt the only ſort uſed among us. The conſumption hereof is very conſiderable among the armourers, cutlers, lockſmiths, glaziers, lapidaries, maſons, &c. ſome of whom uſe it to poliſh and burniſh iron, and ſteel works; others, to cut and ſcollop glaſs, marble, and precious ſtones.

EMETIC, from εμεω, *I vomit*, in medicine, a remedy that excites vomiting; or that purges the ſtomach by the mouth. See Syſtem of Medicine.

EMINENCE, in geography, a little hillock, or aſcent, above the level of the adjoining champain. Eminence is alſo a title of honour given to cardinals. The grand maſter of Malta is likewiſe addreſſed under the quality of *eminence*.

EMINENTLY, is uſed in contradiſtinction to formally, and in the ſame ſenſe with virtually, viz. to denote that a thing poſſeſſes, or contains, any other in a more perfect or higher manner than is required to a formal poſſeſſion thereof.

EMIR, a title of dignity among the Turks, ſignifying a prince. This title was firſt given to the Caliphs; but when they aſſumed the title of Sultans, that of emir remained to their children; as that of Cæſar among the Romans. At length the title came to be attributed to all who were judged to deſcend from Mahomet by his daughter Fatimah, and who wear the green turban inſtead of the white. The Turks make an obſervation, that the emirs, before the fortieth year, are men of the greateſt gravity, learning, and wiſdom; but after this, if they are not great fools, they diſcover ſome ſigns of levity and ſtupidity. This is interpreted by the Turks as a ſort of divine impulſe in token of their birth and ſanctity. The Turks alſo call the vizirs, baſhaws, or governors of provinces, by this name.

EMISSARY, in a political ſenſe, a perſon employed by another to ſound the opinions of people, ſpread certain reports, or act as a ſpy over other people's actions.

Emissary *Veſſels*, in anatomy, the ſame with thoſe more commonly called excretory.

EMISSION, in medicine, a term uſed chiefly to denote the ejaculation of the ſemen, or ſeed, in the act of coition. See Coition and Generation.

EMMENAGOGUES, εμμηναγωγα, in medicine, ſuch remedies as promote the menſes. See Syſtem of Medicine.

EMOLLIENTS, in medicine and pharmacy, are ſuch remedies as ſheath and ſoften the aſperity of the humours, and relax and ſupple the ſolids at the ſame time.

EMOLUMENT, is properly applied to the profits ariſing daily from an office or employ. The word is formed of the Latin, *emolumentum*, which, according to ſome, primarily ſignifies the profits redounding to the miller from his mill; of *molo, molere, to grind*.

EMOTION *and* **Passion**, in the human mind. An internal motion or agitation of the mind, when it paſſeth away without deſire, is denominated *an emotion*: when deſire follows, the motion or agitation is denominated *a paſſion*. A fine face, for example, raiſeth in me a pleaſant feeling: if that feeling vaniſh without producing any effect, it is in proper language an *emotion*; but if the feeling, by reiterated views of the object, becomes ſufficiently ſtrong to occaſion deſire, it loſes its name of emotion, and acquires that of *paſſion*. The ſame holds in all the other paſſions. The painful feeling raiſed in a ſpectator by a ſlight injury done to a ſtranger, being accompanied with no deſire of revenge, is termed an emotion; but that injury raiſeth in the ſtranger a ſtronger emotion, which being accompanied with deſire of revenge, is a paſſion. External expreſſions of diſtreſs produce in the ſpectator a painful feeling, which being ſometimes ſo ſlight as to paſs away without any effect, is an emotion; but if the feeling be ſo ſtrong as to prompt deſire of affording relief, it is a paſſion, and is termed *pity*. Envy is emulation in exceſs: if the exaltation of a competitor be barely diſagreeable, the painful feeling is an emotion; if it produce deſire to depreſs him, it is a paſſion. See Passion.

EMPALEMENT, or **Impalement**, a cruel kind of puniſhment, whereby a ſharp pale or ſtake is thruſt up the fundament, and through the body. We find mention of empaling in Juvenal. It was frequently practiſed in the time of Nero, and continues to be ſo in Turkey.

EMPANELLING, or **Impanelling**, in law, ſignifies the writing and entering into a parchment ſchedule, or roll of paper, by the ſheriff, the names of a jury ſummoned by him to appear for the performance of ſuch public ſervice as juries are employed in.

EMPERESS, **Empress**, *Imperatrix*, the feminine of emperor, applied either to an emperor's wife, or to a woman who rules ſingly over an empire, with all the authority of an emperor; as the empreſs of Ruſſia. See Emperor, Queen, &c.

EMPEROR, a title of honour among the ancient Romans, conferred on a general that had been victorious; and now made to ſignify a ſovereign prince, or ſupreme ruler of an empire. The title of emperor adds nothing to the rights of ſovereignty; it only gives pre-eminence above other ſovereigns. The emperors, however, pretend, that the imperial dignity is more eminent than the regal. It is diſputed whether emperors have the power of diſpoſing of the regal title. However this may be, they have ſometimes taken upon them to erect kingdoms: thus it is that Bohemia, Pruſſia, and Poland, are ſaid to have been raiſed to that dignity. In the eaſt, the title of emperor is more frequent than with us; thus the ſovereign princes of China, Mogul, &c. are called emperors. In the weſt, the title has been a long time reſtrained to the emperors of Germany. The firſt who bore it was Charlemagne, who was crowned by Pope Leo III. in 800. And it is to be obſerved, that there was not a foot of land or territory annexed to the emperor's title. In the year 1723, the Czar of Muſcovy aſſumed the title of emperor of all the Ruſſias. The kings of France were alſo called emperors, when they reigned with their ſons, whom they aſſociated in the crown: thus Hugh Capet was called emperor, and his ſon Robert king. The kings of England were anciently ſtyled emperors, as appears from a charter of king Edgar. The emperor of Germany is a limited monarch in regard to the empire, though he is an abſolute ſovereign in moſt of his hereditary dominions. The late emperors of the Auſtrian family, having hereditary dominions, enumerated all of them in their title. Charles VI. was ſtyled emperor of the Romans, always auguſt, king of Bohemia and Hungary, archduke of Auſtria, &c. The emperor creates dukes, marquiſſes, and other noblemen; and he appoints moſt of the officers, civil and military, in the empire: he is elected by the nine electors; and he ſummons the general diet of the empire.

EMPHASIS, in rhetoric, a force, ſtreſs, or energy, in expreſſion, action, geſture, or the like, which performs the ſame office in ſentences as the accent does in words. The word is Greek, εμφασις, which ſignifies the ſame.

The neceſſity of obſerving propriety of *emphaſis* is ſo great that the true meaning of words cannot be conveyed without it. *Emphaſis* is of two kinds, ſimple, or complex. The former ſerves to point out the plain meaning of any propoſition; the latter alſo marks ſome affection or emotion of the mind, by the uſe of which a diſcourſe receives life and ſpirit, and is rendered capable of producing the nobleſt effects. See Sheridan's Lectures on Elocution, lect. 11.

EMPIRE, **Imperium**, in political geography, a large extent of land, under the juriſdiction or government of an emperor. See Emperor. The moſt ancient empire we read of is that of the Aſſyrians, which was ſubverted through the effeminacy of Sardanapalus; the Perſian empire was deſtroyed through the bad conduct of Darius Codomannus; the Grecian empire, by its being diſmembered among the captains of Alexander the Great; and the Roman empire, through the ill management of the laſt emperors of Rome.

Antiquaries diſtinguiſh between the medals of the upper, and lower, or bas, empire. The curious only value thoſe of the upper empire, which commences with Cæſar, or Auguſtus, and ends in the year of Chriſt 260.

The lower empire comprehends near 1200 years, reckoning as low as the deſtruction of Conſtantinople in 1453. They uſually diſtinguiſh two ages, or periods, of the lower empire: the firſt beginning where the upper ends, viz. with Aurelian, and ending with Anaſtaſius, including 200 years; the ſecond beginning with Anaſtaſius, and ending with the Palæologi, which includes 1000 years.

Empire, or *The Empire*, uſed abſolutely, and without any addition, ſignifies the empire of Germany; called alſo, in juridical acts and laws, The holy Roman empire. Authors are at a loſs under what form of government to range the empire: ſome will have it a monarchical ſtate, by reaſon all the members thereof are forced to aſk the inveſtiture of their ſtates of the emperor, and to take an oath of fidelity to him. Others will have it an ariſtocratic ſtate, by reaſon the emperor cannot determine any thing without the concurrence of the princes: and, laſtly, others will have the empire to be a monarcho-ariſtocratic ſtate.

EMPIRIC, an appellation given to thoſe phyſicians who conduct themſelves wholly by their own experience, without ſtudying phyſic in a regular way. Some even uſe the term, in a ſtill worſe ſenſe, for a quack who preſcribes at random, without being at all acquainted with the principles of the art.

EMPLASTER, popularly called plaſter, a medicine of a ſtiff, glutinous conſiſtence, compoſed of divers ingredients, ſpread on leather, or linen, and applied externally.

EMPYEMA, in medicine, a collection of pus, or purulent matter, in the cavity of the breaſt, diſcharged thither upon the burſting of ſome abſceſs or ulcer in the lungs, or membranes that incloſe the breaſt; or formed from that inſpiſſated ſerum, which Dr. Hunter obſerves is found in large quantities in the cavities of the breaſt, belly, &c. Lond. Med. Obſ. &c. vol. ii. p. 61.

FMPYREUMA, Εμπυρευμα, in chymiſtry, &c. a ſmell or taſte of burning; a quality, or change in bodies that have been burnt, or much ſcorched with fire, ſenſible to the taſte and ſmell. The word is formed of the Greek, εμπυρευειν, *to inflame, kindle*.

EMULATION, is a generous ardour kindled by the brave examples of others, which impels us to imitate, to rival, and, if poſſible to excel them. This paſſion involves in it eſteem of the perſon whoſe attainments or conduct we emulate, of the qualities and actions in which we emulate him; and a deſire of reſemblance, together with a joy ſpringing from the hope of ſucceſs. The word comes originally from the Greek αμιλλα, *diſpute, conteſt*; whence the Latin, *æmulus*, and thence our *emulation*. Plato obſerves of emulation, that it is the daughter of envy; if ſo, there is a great difference between the mother and the offspring; the one is a virtue, and the other a vice. Emulation admires great actions, and ſtrives to imitate them; envy refuſes them the praiſes that are their due; emulation is generous, and only thinks of ſurpaſſing a rival; envy is low, and only ſeeks to leſſen him. Perhaps, therefore, it would be more juſt to ſuppoſe emulation the daughter of admiration: admiration ever, is a principal ingredient in the compoſition of it.

EMULGENT, in anatomy, an epithet beſtowed on thoſe arteries which bring the blood to the kidneys, and thoſe veins which carry back what is ſuperfluous to the cava. See Syſtem of Anatomy, Part IV. Sect. I.

EMULSION, from *emulgere, to milk*, in medicine, a ſoft liquid remedy, of a colour and conſiſtence reſembling milk.

ENALLAGE, in grammar, is when one word is ſubſtituted for another of the ſame part of ſpeech: A ſubſtantive for an adjective, as *exercitus victor*, for *victorioſus*; *ſcelus*, for *ſceleſtus*: a primitive for a derivative, as *Dardana arma*, for *Dardania*: An active for a paſſive, as *nox humida cœlo præcipitat*, for *precipitatur*, &c.

ENAMEL, in general, is a vitrified matter betwixt the parts of which is diſperſed ſome unvitrified matter: hence enamel ought to have all the properties of glaſs except tranſparency.

Enamels have for their baſis a pure cryſtal glaſs or frit, ground up with a fine calx of lead and tin prepared for the purpoſe, with the addition uſually of white ſalt of tartar. Theſe ingredients baked together, are the matter of all enamels, which are made by adding colours of this or that kind in powder to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri (*De Arte Vitriar*) directs only mangeneſe to be added to the matter which conſtitutes the baſis. For azure, zaffer mixed with calx of braſs. For green, calx of braſs with ſcales of iron, or with crocus martis. For black, zaffer with manganeſe, or with crocus martis: or manganeſe with tartar. For red, manganeſe with calx of copper and red tartar. Eor purple, manganeſe with calx of braſs. For yellow, tartar and manganeſe. And for violet-coloured enamel, manganeſe with thrice-calcined braſs.

In making theſe enamels, the following general cautions are neceſſary to be obſerved. 1. That the pots muſt be glazed with white glaſs, and muſt be ſuch as will bear the fire. 2. That the matter of enamels muſt be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it muſt be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamel is this: powder, ſift, and grind, all the colours very nicely, and firſt mix them with one another, and then with the common matter of enamels; then ſet them in pots in a furnace; and when they are well mixed and incorporated, caſt them into water; and when dry, ſet them in a furnace again to melt; and when melted, take a proof of it. If too deep-coloured, add more of the common matter of enamels; and if too pale, add more of the colours. Enamels are uſed either in counterfeiting or imitating precious ſtones, in painting in enamel; or by enamellers, jewellers, and goldſmiths, in gold, ſilver, and other metals. The two firſt kinds are uſually prepared by the workmen themſelves, who are employed in theſe arts. That uſed by jewellers, &c. is brought to us chiefly from Venice or Holland, in little cakes of different ſizes, commonly about four inches diameter, having the mark of the maker ſtruck upon it with a puncheon. It pays the pound 1 s. $7\frac{41}{100}$d. on importation, and draws back 1 s. $5\frac{70}{100}$d. at the rate of 4s. per pound.

Painting in ENAMEL, is a method of painting with enamels, or metalline colours, ground, reduced to powder, and uſed like other colours with a pencil; then fuſed, baked again, and vitrified by force of fire. The art of painting in enamel, or at leaſt of giving colours to glaſs, whence this method of painting was derived, is very ancient, and appears to have been firſt practiſed on earthen veſſels, or potters ware. As early as in the age of Porſenna, king of Tuſcany, we hear of beautiful vaſes made in his territories, enamelled with various figures, though far ſhort of thoſe afterwards made at Faenza, and Caſtel Durante, in the duchy of Urbino, in the time of Raphael and Michael Angelo. There are ſtill ſome of thoſe vaſes extant in the cabinets of antiquaries; in all which, the deſign, or drawing of the figures, is much better than the colouring; for they were at that time only acquainted with two colours, viz. black and white, either for earthen or metal works, excepting a faint kind of carnation for the faces and other parts.

The preſent Method of painting in ENAMEL. This is performed on plates of gold or ſilver, and moſt commonly of copper, enamelled with the white enamel; whereon they paint with colours which are melted in the fire, where they take a brightneſs and luſtre like that of glaſs. This painting is the moſt prized of all for its peculiar brightneſs and vivacity, which is very permanent, the force of its colours not being effaced or ſullied with time as in other painting, and continuing always as freſh as when it came out of the workmens hands. It is uſual in miniature; it being the more difficult the larger it is, by reaſon of certain accidents it is liable to in the operation. Enamelling ſhould only be practiſed on plates of gold, the other metals being leſs pure: copper, for inſtance, ſcales with the application, and yields fumes; and ſilver turns the yellow white. Nor muſt the plate be made flat; for in ſuch caſe, the enamel cracks; to avoid which, they uſually forge them a little round or oval and not too thick. The plate being well and evenly forged, they uſually begin the operation by laying on a couch of white enamel (as we obſerved above) on both ſide, which prevents the metal from ſwelling and bliſtering; and this firſt layer ſerves for the ground of all the other colours. The plate being thus prepared they begin at firſt by drawing out exactly the ſubject to be painted with red vitriol, mixed with oil of ſpike, marking all parts of the deſign very lightly with a ſmall pencil. After this, the colours (which are to be before ground with water in a mortar of agate extremely fine, and mixed with oil of ſpike ſomewhat thick) are to be laid on, obſerving the mixtures and colours that agree to the different parts of the ſubject; for which it is neceſſary to underſtand painting in miniature. But here the workman muſt be very cautious of the good or bad qualities of the oil of ſpike he employs to mix his colours with, for it is very ſubject to adulterations. See OIL.

Great care muſt likewiſe be taken, that the leaſt duſt imaginable come not to your colours while you are either painting or grinding them; for the leaſt ſpeck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red hot, will leave a hole, and ſo deface the work.

When the colours are all laid, the painting muſt be gently dried over a ſlow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red hot in a fire like what the enamellers uſe. Afterwards that part of the painting muſt be paſſed over again which the fire hath any thing effaced, ſtrengthening the ſhades and colours, and committing it again to the fire, obſerving the ſame method as before, which is to be repeated till the work be finiſhed.

ENAMELLING, the art of laying enamel upon metals, as gold, ſilver, copper, &c. and of melting it at the fire, or of making divers curious works in it at a lamp. It ſignifies alſo to paint in enamel.

ENARTHROSIS, Εναρθρωσις, a ſpecies of diarthroſis. Such is that of the huckle bone, &c. See Syſtem of ANATOMY, Part I. Sect. XII.

ENCAMPMENT, in the military. See CAMP.

ENCANTHIS, in ſurgery, denotes a tumor of the caruncula lachrymalis, in the great canthus, or angel of the eye. The word is Greek, εγκανθις, formed of the prepoſition εν and κανθος, *corner of the eye.*

ENCEPPE, in heraldry, denotes chained, or girt round the middle; as is uſual with monkeys, &c.

ENCHANTMENT, of *in*, and *canto*, *I ſing*, denotes certain words and ceremonies uſed by magicians in the practice of their pretended and deluding art; thus called, becauſe the *formulæ* of their *enchantment* were generally compoſed in verſe, and deſigned to be ſung. See MAGIC.

ENCHASING, INCHASING, or CHASING, the art of enriching and beautifying gold, ſilver, and other metal-works, by ſome deſign or figures repreſented thereon, in low relievo. Chaſing is only practiſed on hollow, thin works; as watch caſes, cane-heads, tweezer caſes, or the like. It is performed by punching or driving out the metal to form the figures from within ſide, ſo as to ſtand out prominent from the plane or ſurface of the metal. In order to this, they have a great number of fine ſteel blocks, or puncheons, of divers ſizes; and the deſign being drawn on the ſurface of the metal, they apply the inſide upon the heads or tips of theſe blocks, directly under the lines or parts of the figures. Then, with a fine hammer, ſtriking on the metal ſuſtained by the block, the metal yields, and the block makes an indenture or cavity on the inſide; correſpondent to which, there is a prominence on the outſide, which is to ſtand for part of the figure. Thus the workman proceeds to chaſe and finiſh all the parts, by ſucceſſive applications of the block and hammer to the ſeveral parts of the deſign. And it is ſurpriſing, with what beauty and juſtneſs, by this ſimple piece of mechaniſm, the artiſts in this kind will repreſent foliages, groteſques, animals, hiſtories, &c.

ENCLITICA, in grammar, particles which are ſo cloſely united with other words, as to ſeem part of them as in *virumque*, &c. There are three enclitic particles in Latin, viz. *que*, *ne*, *ve*.

ENCOPE, of εν and κοπτω, *I cut*, in ſurgery, an inciſion of any part; as in a gangrene, &c.

ENCOUNTERS, in military language, a combat between two perſons; and the term is alſo more generally applied to attacks or battles between ſmall or large armies.

ENCYCLOPÆDIA, the circle or chain of arts and ſciences. The word is compounded of the prepoſition εν, *in*, κυκλος, *circle*, and παιδεια, *ſcience*, *doctrine*, *diſcipline*, *learning*; the root being παις, *child*, *infant*. The Greeks uſed the term for the knowledge of the ſeven liberal arts, and the poſſeſſion of all the ſciences. *Orbis ille doctrinæ, quem Græci* εγκυκλοπαιδειαν *vocant*, ſays Quintillian. It is ſometimes alſo written, κυκλοπαιδεια, *cyclopædia*. Vitruvius, in the preface to his ſixth book, calls it, *encyclios diſciplina*. See CYCLOPÆDIA.

ENDEMIC *Diſeaſe*, of εν and δεμος, *people*, that which affects many people together in the ſame country, as proceeding from ſome cauſe peculiar to the country where it reigns.

ENDENTED, DENTED, or INDENTED, in heraldry. See INDENTED. Endented, is alſo applied to a feſs or pale, and other triangular pieces, when divided alternately between two different colours. Coupé, or endented with or and azure.

ENDIVE, or SUCCORY, *cithorium*, in botany, a genus of the polygamia equalis order, belonging to the ſyngeneſia claſs of plants. The curled endive is now much cultivated in the Engliſh gardens, being one of the principal ingredients in the ſallads of autumn and winter; for which purpoſe it is continued as long as the ſeaſon will permit.

ENDORSE, in heraldry, an ordinary, containing the eighth part of a pale. See Syſtem of HERALDRY, Plate IV.

ENDORSEMENT, of *in* and *dorſum*, *back*, is particularly uſed in commerce, for a writing on the back of a bill of exchange by the proprietor or bearer, either thereby to transfer it to ſome other, or to render it payable to the order of ſome other, or elſe to ſerve for an acquittance or receipt. The endorſement is only the name of the proprietor, or endorſer. Note, when the endorſement of a bill of exchange is to render it payable to another, it is called an order.

ENDORSING, or INDORSING, in law, implies the writing on the back ſide of a deed, inſtrument, &c. Something relating to the matters contained therein.

ENDOWMENT, or INDOWMENT, the giving or aſſigning of a dower to a woman. The word is alſo uſed figuratively, for the ſetting forth or ſevering a ſufficient portion for a vicar, towards his perpetual maintenance, when the benefice is appropriated; whence ſuch a vicarage is called a vicarage endowed.

ENERGETICAL *Bodies* or *Particles*, are ſuch as are eminently active, and which produce manifeſt operations of various natures, according to the various circumſtances, and motions of ſuch bodies or particles.

ENERGY, an uncommon force or ſtrength in a diſcourſe, a ſentence, or a word. See EMPHASIS. The word is Greek ενεργεια, formed of the prepoſition εν, and εργον, *work, labour*.

ENERVATING, the act of deſtroying the force, uſe, or office of the nerves, either by cutting them, by weakening them with debauchery, or by ſome other violence. Exceſs of wine, and other ſtrong, hot, ſpirituous liquors, enervate or weaken the nerves. When they would render a horſe uſeleſs, they enervate him, or cut his nerves.

ENFANS *Perdus*, a French phraſe, uſed in war to ſignify the ſoldiers who march at the head of a body of forces appointed to ſuſtain them, in order to begin an attack, make an aſſault, or force a poſt. The word literally imports loſt children, on account of the imminent danger they are expoſed to. In Engliſh, they are called the forlorn, or forlorn hope. At preſent, the grenadiers uſually begin ſuch attacks.

ENFILADE, in war, is applied to thoſe trenches, and other lines, which are ranged in a right line, and ſo may be ſcoured or ſwept by the cannon lengthways, or in the direction of the line, and rendered almoſt defenceleſs. Care muſt be taken that the lines be not enfiled, or enfiladed; on the contrary, the covert line muſt be enfiladed, that the enemy may be driven out of it. The laſt boyau, or gut of the trenches, is ſubject to be enfiladed, that is, to be ſcoured according to its length. A battery *d'enfilade*, is that where the cannon ſweep a right line. A poſt, or command *d'enfilade*, is a height from which one may ſweep a whole line at once.

ENFILED, in heraldry, when the head of a man or beaſt is placed on the blade of a ſword; the ſword is ſaid to be enfiled with a head, &c.

ENFRANCHISEMENT, the incorporating any man into a ſociety or body politic. Thus, he that by charter is made denizen of England, is ſaid to be enfranchiſed. The like is underſtood of a perſon made a citizen of London, or other city or corporate town; becauſe he is thereby made partaker of the liberties appertaining to the corporation whereof he is enfranchiſed.

ENGAGEMENT, in a naval ſenſe, denotes a particular or general battle at ſea, or an action of hoſtility between ſingle ſhips, or or detachments, or ſquadrons of men of war. See NAVAL TACTICS.

ENGAGEMENT, in Engliſh hiſtory, was the obligation impoſed by Oliver Cromwell required to be ſigned by every member of the firſt parliament in 1654, aſſembled by his authority, after he was declared protector, viz. I *A. B.* do hereby freely promiſe and engage myſelf to be true and faithful to the Lord protector, and to the commomwealth of England, Scotland, and Ireland, and ſhall not (according to the tenure of the indenture whereby I am returned to ſerve in this preſent parliament) propoſe or give any conſent to alter the government, as it is ſettled in one ſingle perſon and a parliament. Many, who refuſed to ſign this engagement, were excluded from the houſe.

ENGENDERING, or INGENDERING, the act of begetting or producing the kind, by way of generation. The term is likewiſe applied to other productions of nature; thus, meteors are ſaid to be engendered in the middle region of the air. Crude fruits engender worms. The ancients believed, that inſects were engendered of putrefaction.

ENGINE, in mechanics, a compound machine, conſiſting of ſeveral ſimple ones, as wheels, ſcrews, levers, or the like, combined together, in order to lift, caſt, or ſuſtain a weight, or produce ſome other conſiderable effect, ſo as to ſave either time or force. The word is formed of the French, *engine*; of the Latin, *ingenium, wit*; becauſe of the ingenuity required in the contrivance of engines, to augment the effect of moving powers. See Syſtem of MECHANICS, Plate II.

ENGINEER, in the military art, an able expert man, who, by a perfect knowledge in mathematics, delineates upon paper, or marks upon the ground, all ſorts of forts, and other works proper for offence and defence. He ſhould underſtand the art of fortification, ſo as to be able, not only to diſcover the defects of a place, but to find a remedy proper for them; as alſo how to make an attack upon, as well as to defend the place. Engineers are extremely neceſſary for theſe purpoſes; wherefore it is requiſite, that, beſides being ingenious, they ſhould be brave in proportion. When at a ſiege the engineers have narrowly ſurveyed the place, they are to make their report to the general, by acquainting him which part they judge the weakeſt, and where approaches may be made with moſt ſucceſs. Their buſineſs is alſo to delineate the lines of circumvallation and contravallation, taking all the advantages of the ground; to mark out the trenches, places of arms, batteries and lodgments, taking care that none of their works be flanked or diſcovered from the place. After making a faithful report to the general of what is a doing, the engineers are to demand a ſufficient number of workmen and utenſils, and whatever elſe is neceſſary.

ENGLANTE, in heraldry, a French term for an oak tree, when bearing acorns.

ENGLISH, in a general ſenſe, ſomething that relates to the country, or people of England. We ſay the Engliſh crown, Engliſh copperas, Engliſh names, Engliſh money, Engliſh meaſures, Engliſh weights, &c.

ENGLISH, or the ENGLISH *Tongue*, the language ſpoken by the people of England, and, with ſome variation, by thoſe of Scotland, as well as part of Ireland, and the reſt of the Britiſh dominions. The ancient language of Britain is generally allowed to have been the ſame with the Gaulic, or French; this iſland, in all probability, having been firſt peopled from Gallia, as both Cæſar and Tacitus affirm, and prove by many ſtrong and concluſive arguments, as by their religion, manners, cuſtoms, and the nearneſs of their ſituation. But now we have very ſmall remains of the ancient Britiſh tongue, except in Wales, Cornwall, the iſlands and Highlands of Scotland, part of Ireland, and ſome provinces of France; which will not appear ſtrange, when what follows is conſidered. Julius Cæſar, ſome time before the birth of our Saviour, made a deſcent upon Britain, though he may be ſaid rather to have diſcovered than conquered it; but, about the year of Chriſt 45, in the time of Claudius, Aulus Plautius was ſent over with ſome Roman forces, by whom two kings of the Britons, Togodumnus and Caractacus were both overcome in battle; whereupon a Roman colony was planted at Malden in Eſſex, and the ſouthern parts of the iſland were reduced to the form of a Roman province; after that, the iſland was conquered as far north as the friths of Dunbarton and Edinburgh, by Agricola, in the time of Domitian; whereupon a great number of the Britons, in the conquered part of the iſland, retired to the weſt part called Wales, carrying their language with them. The greateſt part of Britain being thus become a Roman province, the Roman legions, who reſided in Britain for above 200 years, undoubtedly diſſeminated the Latin tongue; and the people being afterwards governed by laws written in Latin, muſt neceſſarily make a mixture of languages. This ſeems to have been the firſt mutation the language of Britain ſuffered. Thus the Britiſh tongue continued, for ſome time, mixed with the provincial Latin, till, the Roman legions being called home, the Scots and Picts took the opportunity to attack and harraſs England: upon which, K. Vortigern, about the year 440, called the Saxons to his aſſiſtance; who came over with ſeveral of their neighbours, and having repulſed the Scots and Picts, were rewarded for their ſervices with the iſle of Thanet, and the whole county of Kent; but growing too powerful, and not being contented with their allotment, diſpoſſeſſed the inhabitants of all the country on this ſide of the Severn: thus the Britiſh tongue was in a great meaſure deſtroyed, and the Saxon introduced in its ſtead. What the Saxon tongue was long before the conqueſt, about the year 700, we may obſerve in the moſt ancient manuſcript of that language, which is a gloſs on the Evangeliſts, by biſhop Edfrid, in which the three firſt articles of the Lord's prayer run thus:

"Uren fader thic arth in heofnas, ſic gehalgud thin noma, ſo cymeth thin ric. Sic thin willa ſue is heofnas, and in eortho, &c." In the beginning of the ninth century the Danes invaded England; and getting a footing in the northern and eaſtern parts of the country, their power gradually increaſed, and they became ſole maſters of it in about 200 years. By this means the ancient Britiſh obtained a tincture of the Daniſh language; but their government being of no long continuance, did not make ſo great an alteration in the Anglo-Saxon, as the next revolution, when the whole land, A. D. 1067, was ſubdued by William the conqueror, duke of Normandy in France; for the Normans, as a monument of their conqueſt, endeavoured to make their language as generally received as their commands, and thereby rendered the Britiſh language an entire medley. About the year 900, the Lord's prayer, in the ancient Anglo-Saxon, ran thus:

"Thue ur fader the eart on heofenum, ſi thin nama gehalgod; cume thin rice ſi thin willa on eorthan ſwa, ſwo on heofenum, &c." About the year 1160, under Henry II. it was rendered thus by pope Adrian, an Engliſhman, in rhyme:

"Ure fader in heaven rich,
"Thy name be halyed ever lich,
"Thou bring us thy michell bliſſe:
"Als hit in heaven y doe,
"Evar in yearth beene it alſo, &c."

Dr. Hicks gives us an extroardinary ſpecimen of the Engliſh, as ſpoken in the year 1385, upon the very ſubject of the Engliſh tongue. "As it is knowe how meny maner peple beeth in this lond; ther beeth alſo ſo many dyvers longages and tonges. Notheleſs Walſchemen and Scots that beeth nought medled with other nation, holdeth wel nyh hir firſte longage and ſpeche; but yif the Scottes, that were ſometime confederate and woned with the Picts, drawe ſomewhat after hir ſpeche; but the Flemynges, that woneth on the weſt ſide of Wales, haveth loſt her ſtrange ſpech, and ſpeketh Sexonliche now. Alſo Engliſhemen, they had from the bygynnynge thre maner ſpeche; northerne, ſoutherne, and middel ſpeche in the middel of the lond, as they come of thre maner of peple of Germania: notheleſs by commyxtion and mellynge firſt with Danes, and afterwards with Normans, in meny the contrary longage is apayred (*corrupted*.)

"This apayrynge of the burth of the tunge is bycauſe of tweie things; oon is for children in ſcole agenſt the uſuage and maner of all other nations, beeth compelled for to leve hire own longage, and for to conſtrue hir leſſons and here thynges in French, and ſo they haveth ſethe Normans come firſt into Engelond. Alſo gentlemen children beeth taught to ſpeke Frenſche, from the tyme that they beeth roked in here cradel, and kunneth ſpeke and play with a childe's broche; and uplondiſſche men will lykne hymſelf to gentilmen, and fondeth with great beſyneſſe for to ſpeak Frenſche to be told of. Hit ſeemeth a great wonder how Engliſhemen and her own longage and tonge is ſo dyverſe of ſown in this oon iland; and the longage of Normandie is comlynge of another lond, and hath oon maner ſoun amonge alle men that ſpeketh hit arigt in Engelond. Alſo of the aforeſaid Saxon tonge that is deled (*divided*) a three, and is abide ſcarceliche with fewe uplondiſſche men, is greet wonder. For men of the eſt, with men of the weſt, is, as it were, undir the ſame partie of hevene accordeth more in ſowynge of ſpeche, than men of the north with men of the ſouth. Therefore it is that Mercii, that beeth men of myddel Engelond, as it were, parteners of the endes, underſtondeth bettre the ſide longes northerne and ſoutherne, than northerne and ſoutherne underſtondeth either other. All the longage of the Northumbers and ſpechialiche at York, is ſo ſcharp, ſlitting and frotynge, and unſchape, that we ſoutherne men may that longage unnethe underſtonde, &c.

In the year 1537, the Lord's prayer was printed as follows: " O oure father which arte in heven, hallowed be thy name: let thy kingdome come, thy will be fulfilled as well in earth as it is in heven; geve us this daye in dayly bred, &c." Where it may be obſerved, that the diction is brought almoſt to the preſent ſtandard, the chief variations being only in the orthography. By theſe inſtances, and many others that might be given, it appears, that the Engliſh Saxon language, of which the Normans deſpoiled us in a great meaſure, had its beauties, was ſignificant and emphatical, and preferable to what they impoſed on us. " Great, verily, (ſays Camden), was the glory of onr tongue before the Norman conqueſt, in this, that the old Engliſh could expreſs moſt aptly, all the conceptions of the mind in their own tongue, without borrowing from any." Of this he gives ſeveral examples.

Having thus ſhewn how the ancient Britiſh language was in a manner extirpated by the Romans, Danes, and Saxons, and ſucceeded by the Saxon,and after that the Saxon blended with the Norman French, we ſhall now mention two other cauſes of change in the language. The firſt of theſe is owing to the Britons having been a long time a trading nation, whereby offices dignities, names of wares, and terms of traffic are introduced, which we take with the wares from the perſons of whom we have them and form them anew, according to the genius of our own tongue; and beſides this change in the language, ariſing from commerce, Britain's having been a conſiderable time ſubject to the ſee of Rome, in eccleſiaſtical affairs, muſt unavoidably have introduced ſome Italian words among us. Secondly, As to the particular properties of a language, our tongue has undergone no ſmall mutation, or rather has received no ſmall improvement upon that account: for, as to the Greek and Latin, the learned have together with the arts and ſciences now rendered familiar among us, introduced abundance; nay, almoſt all the terms of art in the mathematics, philoſophy, phyſic, and anatomy; and we have entertained many more from the Latin, French, &c. for the ſake of neatneſs and elegancy: ſo that, at this day, our language, which, about 1800 years ago, was the ancient Britiſh, or Welſh, &c. is now a mixture of Saxon, Teutonic, Dutch, Daniſh, Norman, and modern French, embelliſhed with the Greek and Latin. Yet this, in our opinion, is ſo far from being a diſadvantage to the Engliſh tongue as now ſpoken, (for all languages have undergone changes, and do continually participate with each other), that has ſo enriched it as now to become the moſt copious, ſignificant, fluent, courteous, and maſculine language in Europe, if not in the world.

ENGOULANT, in heraldry, ſwallowing, as applied to ſerpents, &c.

ENGRAFTING, GRAFTING, or GRAFFING, in gardening, the art, or act of inſerting, or fixing, a cyon, ſhoot, or bud of one tree, into the ſtock of another; in order to correct, and improve its fruit. See Treatiſe on GARDENING.

ENGRAILED, or INGRAILND, in heraldry (from the French *grêle, hail*) is when a thing is preſented with its edges ragged, or notched, ſemicircularly, as if broken by ſomething falling on it.

ENGRAVING, the art of cutting metals and precious ſtones, and repreſenting thereon figures, letters, or whatever device, or deſign, the artiſt fancies. Engraving, properly a branch of ſculpture, is divided into ſeveral other branches, according to the matter whereon it is employed, and the manner of performing it. For the rudeſt branch, that of engraving on wood, ſee *Cutting in* WOOD.

ENGRAVING *on Copper*, the making, correſpondently ſome delineated figure or deſign, ſuch concave lines on a ſmooth ſurface of copper, either by cutting or corroſion, as render it capable, when charged properly with any coloured fluid, of imparting by compreſſion an exact repreſentation of the figure or deſign to paper or parchment.

Whether we conſider the art of engraving, with regard to the utility and pleaſure it affords, or the difficulty that attends its execution, we cannot but confeſs, that on every account it deſerves a diſtinguiſhed rank among the polite arts. It is by means of this art that the cabinets of the curious are adorned with the portraits of the greateſt men of all ages and all nations; that their memories, their moſt remarkable and moſt glorious actions, are tranſmitted to the lateſt poſterity. It is by this art alſo, that the paintings of the greateſt maſters are multiplied to a boundleſs number; and that the lovers of the polite arts, diffuſed over the face of the whole earth, are enabled to enjoy thoſe beauties which their diſtant ſituations ſeemed to have for ever debarred them; and perſons of moderate fortunes are hereby enabled to become poſſeſſed of all the ſpirit, and all the poetry, that are contained in thoſe miracles of art, which ſeemed to have been reſerved for the temples of Italy, or, the cabinets of princes. When we reflect, moreover, that the engraver, beſide the beauties of poetic compoſition, and the artful ordinance of deſign, is to expreſs, merely by the means of light and ſhade, all the various tints of colours and clair obſcure; to give a relief to each figure, and a truth to each object; that he is now to paint a ſky ſerene and bright, and then loaded with dark clouds; now the pure tranquil ſtream, and then the foaming, raging ſea; that here he is to expreſs the character of the man, ſtrongly marked in his countenance, and there the minuteſt ornament of his dreſs; in a word, that he is to repreſent all, even the moſt difficult objects in nature; we cannot ſufficiently admire the vaſt improvements in this art, and that degree of perfection to which it is at this day arrived.

The invention of this art is ſaid to be owing to chance. In the 15th century, a goldſmith of Florence, who was in much eſteem with pope Innocent X. having placed a ſheet of oiled paper under a plate of ſilver that was engraved, and on which, by accident, he had laid a heavy weight, was much ſurpriſed to find, a few days after, a complete impreſſion of the plate upon the paper. This he communicated to ſome able painters, his cotemporaries; who profiting by that example, laid the firſt foundation of the art of engraving: which Raphael in Italy, and Albert Durer in Germany, greatly improved; and which the Italian, French, and Flemiſh maſters, ſuch as Michal Angelo, Edinlinck, Rembrandt, &c. and lately ſome of the Britiſh artiſts, have ſucceſſively carried to the higheſt degree of excellence.

The method by which engraving is performed, by the graver or tool alone, is in common language the only kind called ſtroke engraving; that by corroſion with aqua fortis, which is generally called etching: and by entirely covering the ſurface of a copper plate with a dark ground, in ſuch a manner, that the whole may produce the effect of black in an impreſſion; and then ſcraping or burniſhing away part of the dark colour, ſo as to cauſe the remainder to have the effect of a painting, which laſt kind is called ſcraping in mezzotinto. Of late the methods of producing effects upon copper have been ſo various, that it would be endleſs to deſcribe them. But there are two methods very much in preſent practice, the firſt is ſtippling, which is performed by dots on the copper, and by this means worked up in ſuch a manner, as to have ſomething of the appearance of a mezzotinto; but infinitely preferable, as it will afford a ſofter, and yet more ſpirited effect. The other method is by aquatinta, which we have deſcribed under that article.

Engraving with the tool was the kind originally practiſed, and it is yet retained for many purpoſes. For though etching be more eaſy, and other advantages attend it; yet where great regularity and exactneſs of the ſtroke or lines are required, the working with the graver is much more effectual: on which account it is more ſuitable to the preciſion neceſſary in the execution of portraits; as there every thing the moſt minute muſt be made out and expreſſed, according to the original ſubject, without any licenſe to the fancy of the deſigner in deviating from it or varying the effect either by that maſterly negligence and ſimplicity in ſome parts, or thoſe bold ſallies of the imagination and hand in others, which give ſpirit and force to hiſtory-painting.

The principal inſtruments uſed in engraving with the tool, are gravers, ſcrapers, a burniſher, an oil-ſtone, and a cuſhion for bearing the plates. Gravers are made in ſeveral forms with reſpect to the points, ſome being ſquare, others lozenge; the ſquare graver for cutting board, and the lozenge for more delicate deep and fine ſtrokes. The dry point, or needle, which has been of late much uſed in engraving, is a tool like an etching point, which being drawn hard on the copper, cuts a ſtroke, and raiſes a burr; the burr is ſcraped off, and there remains a ſtroke more ſoft and delicate than can be produced in any other way.

The burniſher is uſed to aſſiſt in the engraving on ſome occaſions, as well as to poliſh the plates. The principal application of it in engraving, beſides its uſe in poliſhing the plates, is to take out any ſcratches, or accidental defacings, that may happen to the plates during the engraving; or to leſſen the effect of any parts that may be too ſtrongly marked in the work, and require to be taken down. A cuſhion, as it is called, is likewiſe generally uſed for ſupporting the plate in ſuch a manner, that it may be turned every way with eaſe. It is a bag of leather filled with ſand, which ſhould be of the ſize that will beſt ſuit the plates it is intended to bear. They are round, and about nine inches over, and three inches in thickneſs.

In making circular or other curve lines, hold your hand and graver ſteadily; and as you work, turn your plate upon the cuſhion againſt your graver, otherwiſe it will be impoſſible for you to make any circular or curved lines with that neatneſs and command of hand you by this means may. After part of the work is engraved, it is neceſſary to ſcrape it with the ſcraper, or graver, paſſed in the moſt level direction over the plate to take off the roughneſs formed by the cutting of the graver; but great care muſt be taken not to incline the edge of the ſcraper or tool uſed, in ſuch a manner that it may take the leaſt hold of the copper, as it would otherwiſe produce falſe ſtrokes or ſcratches in the engraving: and that engraved work may be rendered more viſible, it may afterwards be rubbed over with a roll of felt dipped in oil.

It is very neceſſary for thoſe, who learn to engrave in perfection, to endeavour, by frequent trials, to acquire the habit of making ſuch ſtrokes both ſtraight and curving, by lightning or ſinking the graver with the hand, according to the occaſion. If, after finiſhing the deſign, any ſcratches appear, or any part of the engraving be falſely executed, ſuch ſcratches, or faulty parts, muſt be taken out by the burniſher, and further poliſhed, if neceſſary, by the above-mentioned roll.

Engraving *on Precious Stones*, is the repreſenting of figures, or devices, in relievo or indented, on divers kinds of hard poliſhed ſtones. The art of engraving on precious ſtones is one of thoſe wherein the ancients excelled; there being divers antique agates, cornelians, and onyxes, which ſurpaſs any thing of that kind the moderns have produced. Pyrgoteles among the Greeks, and Dioſcorides under the firſt emperors of Rome, are the moſt eminent engravers we read of: the former was ſo eſteemed by Alexander, that he forbade any body elſe to engrave his head; Auguſtus's head, engraven by the latter, was deemed ſo beautiful, that the ſucceeding emperors choſe it for their ſeal. All the polite arts having been buried under the ruins of the Roman empire, the art of engraving on ſtones met with the ſame fate. It was retrieved in Italy at the beginning of the 15th century, when one John of Florence, and after him Dominic of Milan, perfomed works of this kind no way to be deſpiſed. From that time, ſuch ſculptures became common enough in Europe, and particularly in Germany, whence great numbers were ſent into other countries: but they came ſhort of the beauty of thoſe of the ancients, eſpecially thoſe on precious ſtones; for, as to thoſe on cryſtal, the Germans, and, after their example, the French, &c. have ſucceeded well enough. In this branch of engraving, they make uſe either of the diamond, or of emery.

The diamond, which is the hardeſt of all ſtones, is only cut by itſelf, or with its own matter. The firſt thing to be done in this branch of engraving, is to cement two rough diamonds to the ends of two ſticks big enough to hold them ſteady in the hand, and to rub or grind them againſt each other till they be brought to the form deſired. The duſt or powder that is rubbed off ſerves afterwards to poliſh them, which is performed with a kind of mill that turns a wheel of ſoft iron. The diamond is fixed in a braſs diſh; and, thus applied to the wheel, is covered with diamond-duſt, mixed up with oil of olives; and when the diamond is to be cut facet-wiſe, they apply firſt one face, then another, to the wheel. Rubies, ſapphires, and topazes, are cut and formed the ſame way on a copper wheel, and poliſhed with tripoli diluted in water. As to agates, amethyſts, emeralds, hyacinths, granates, rubies, and others of the ſofter ſtones, they are cut on a leaden wheel, moiſtened with emery and water, and poliſhed with tripoli on a pewter wheel. Lapis-lazuli, opal, &c. are poliſhed on a wooden wheel. To faſhion and engrave vaſes of agate, cryſtal, lapis-lazuli, or the like, they make uſe of a kind of lathe, like that uſed by pewterers to hold the veſſels, which are to be wrought with proper tools: that of the engraver generally holds the tools, which are turned by a wheel; and the veſſel is held to them to be cut and engraved, either in relievo or otherwiſe; the tools being moiſtened from time to time with diamond-duſt and oil, or at leaſt emery and water. To engrave figures or devices on any of theſe ſtones, when poliſhed, ſuch as ſeals, &c. they uſe a little iron wheel, the ends of whoſe axis are received within two pieces of iron, placed upright, as in the turner's lathe; and to be brought cloſer, or ſet further apart at pleaſure: at one end of the axis are fitted the proper tools, being kept tight by a ſcrew. Laſtly, The wheel is turned by the fort, and the ſtone applied by the hand to the tool, and is ſhifted and conducted as occaſion requires. The tools are generally of iron, and ſometimes of braſs; their form is various, but it generally bears ſome reſemblance to chiſels, gouges, &c. Some have ſmall round heads, like buttons, others like ferrels, to take the pieces out, and others flat, &c. When the ſtone has been engraven, it is poliſhed on wheels of hair-bruſhes and tripoli.

Engraving *on Steel* is chiefly employed in cutting ſeals, punches, matrices, and dyes proper for ſtriking coins, medals, and counters. The method of engraving with the inſtruments, &c. is the ſame for coins as for medals and counters: all the difference conſiſts in their greater or leſs relievo; the relievo of coins being much leſs conſiderably than that of medals, and that of counters, ſtill leſs than that of coins.

Engravers in ſteel commonly begin with punches, which are in relievo, and ſerve for making the creux, or cavities, of the matrices and dyes: though ſometimes they begin with the creux, or hollowneſs; but then it is only when the intended work is to be cut very ſhallow. The firſt thing done, is that of deſigning the figures; the next is the moulding them in wax, of the ſize and depth they are to lie, and from this wax the punch is engraven. When the punch is finiſhed, they give it a very high temper, that it may the better bear the blows of the hammer with which it is ſtruck to give the impreſſion to the matrix. The ſteel is made hot to ſoften it, that it may the more readily take the impreſſion of the punch; and after ſtriking the punch on it, in this ſtate, they proceed to touch up or finiſh the ſtrokes and lines, where by reaſon of their fineneſs or the too great relievo they are any thing defective, with ſteel gravers of different kinds, chiſels, flatters, &c. being the principal inſtruments uſed in graving on ſteel. The figure being thus finiſhed, they proceed to engrave the reſt of the medal, as the mouldings of the border, the engrailed ring, letters, &c. with little ſteel punches well tempered, and very ſharp.

ENGROSSING, the writing a deed over fair, and in proper legible characters. Among lawyers it more particularly means the copying of any writing fair upon parchment, or ſtamped paper.

Engrossing, in commerce, ſignifies the buying up any commodity in the groſs, or foreſtalling the market.

ENGUICHE, in heraldry, is ſaid of the great mouth of a hunting horn, when its rim is of a different colour from that of the horn itſelf.

ENHANCED, in heraldry, placed high in the field.

ENIGMA. See Ænigma.

ENMANCHE, in heraldry, is when a chief has two lines drawn from the middle of the upper edge, to the ſides, the depth of half the chief; the two lines including an obtuſe angel, whoſe vertex is the centre of the top of the chief.

ENNEAGON, in geometry, a figure of nine angles, and nine ſides. The word is formed of εννεα, *nine*; and γωνια, *angle*.

ENNEANDRIA, in botany, the ninth claſs of plants; in the Linnæan Syſtem. The word is derived from the Greek εννεα, *nine*, and ανηρ, *male*. This claſs comprehends three orders; viz. the monogynia, the trigynia, and hexagynia. See Syſtem of Botany, Sect. V. and Plate IV.

ENORMOUS, ſomething exceſſive, or monſtrous, eſpecially of bulk. The coluſſus of Rhodes was of an enormous ſtature.

ENSEMBLE, a French term, ſometimes uſed in our language, literally ſignifying *together*, or *one with another*; being formed from the Latin, *in*, and *ſimul*. In architecture, we ſay, the *enſemble*, or *tout enſemble* of a building; meaning the work or compoſition, conſidered together, and not in parts; and ſometimes alſo the relative proportion of the parts to the whole. Alſo thoſe pieces of building make a fine *enſemble*.

To judge well of a ſtatue, or other work of ſculpture, one muſt firſt examine whether the *enſemble* be good. The *tout enſemble* of a painting, is that harmony which reſults from the diſtribution of the ſeveral objects or figures whereof the whole is compoſed. This picture is good, taking the parts ſeparately; but the *tout enſemble* is bad.

ENSIFORM *Leaf*, in botany. See Syſtem of Botany, Plate I. *fig*. 56.

ENSIGN, in the military art, a banner or colours under which ſoldiers are ranged, according to the different companies or parties they belong to. See Flag, Colours, Standard, &c.

Ensign is alſo the officer that carries the colours, being the loweſt commiſſioned officer in a company of foot, ſubordinate to the captain and lieutenant. It is a very honourable and proper poſt for a young gentleman at his firſt coming into the army: he is to carry the colours both in aſſault, day of battle, &c. and ſhould not quit them but with his life; he is always to carry them himſelf on his left ſhoulder: only on a march he may have them carried by a ſoldier. If the enſign is killed, the captain is to carry the colours in his ſtead.

Naval Ensign, a large ſtandard or banner hoiſted on a long pole erected over the poop, and called the *enſign ſtaff*. The enſign is uſed to diſtinguiſh the ſhips of different nations from each other, as alſo to characteriſe the different ſquadrons of the navy. The Britiſh enſign in ſhips of war is known by a double croſs, viz. that of St. George and St. Andrew, formed upon a field which is either red, white, or blue.

ENTABLATURE, in architecture, is that part of an order of column which is over the capital, comprehending the architrave, frize, and corniche. See Syſtem of Architecture, on the Orders of Architecture in general, and Plate VI.

ENTAIL, in law, ſignifies fee tail, or fee entailed, that is, abridged, curtailed, or limited to certain conditions.

ENTEROLOGY, from εντερον, *inteſtinum*, a gut, and λογος, *ſermo*, diſcourſe) is properly a treatiſe on the bowels. Though the word is generally underſtood to include the contents of three cavities, head, breaſt, and all the viſcera or belly.

ENTHYMEME, in logic and rhetoric, an argument conſiſting only of two propoſitions, an antecedent, and a conſequent deduced from it.

ENTITY, in the ſchool philoſophy, a phyſical ens, or being, conſidered according to what it is in its natural capacity.

ENTOMOLOGY, the ſcience of inſects, or that part of zoology which treats of inſects.

SYSTEM OF ENTOMOLOGY.

PART. I.

INTRODUCTION.

THIS ſcience, although it is only a ſmall part of zoology, yet in the number of individuals and ſpecies it exceeds all the other parts united; inſects are the moſt numerous tribe of animals though leaſt in ſize, and notwithſtanding the extreme minuteneſs, admirable ſkill and perfect mechaniſm which pervade the whole, the omnipotence and omniſcience of the great Creator is manifeſtly diſplayed, and that divine rule and order which regulate all his works are equally apparent in the moſt minute as in the largeſt of his creatures. Inſects therefore aſſuredly claim a proper degree of attention: the effects produced by them are inimitable by art, and oftentimes ſo great and incomprehenſible as to exceed the bounds of human reaſon: but notwithſtanding their univerſality, their variety and the exceſſive beauty of ſome particular ſpecies, and that thirſt for novelty inherent in man, the ſtudy of theſe minute animals has never been cultivated with that ardor and ſucceſs which has fallen to the ſhare of botany. This probably aroſe from the many difficulties attending it; the minuteneſs of their form and the ſingularity of their transformations, together with the idea which formerly prevailed, that their generation was equivocal, and their production inconſtant, ſpontaneouſly iſſuing without law or order, in immenſe varieties from the putrified remains of animals and other ſubſtances. However ridiculous and abſurd ſuch an opinion may now appear, it was almoſt univerſally credited, till the valuable and numerous experiments of Harvey and Rhedi enlightened the ſubject; and clearly and fully demonſtrated that every living thing was produced from an egg. There were indeed other reaſons that operated powerfully againſt this ſtudy, viz. the difficulty of aſcertaining what an inſect was, and the terror that many people have for particular ſpecies: again, a man was looked upon with contempt who employed himſelf in thoſe purſuits, and often ſtigmatized with the opprobrious epithets of fool or madman, for thus, as it was called, miſpending his time, though in exploring the works of that Being from whom our own exiſtence is derived.

With a view to render this ſtudy more eaſy, and a deſire to make it more general, it is our intention to elucidate it, firſt by giving a ſhort liſt of the authors who have diſtinguiſhed themſelves in this branch of knowledge, then to add ſome obſervations on the ſexes, food, modes of living, uſes, deſtructive properties and metamorphoſes of inſects, with conciſe directions for catching and preſerving them; alſo a complete definition of an inſect, and a ſcientific deſcription of its component parts; and conclude with a clear and comprehenſive view of that admirable ſyſtem laid down by Linnæus.

HISTORY.

Among the ancients, Ariſtotle and Pliny did not neglect the contemplation of inſects; but Ariſtotle, rich as he is in remarks on their general œconomy has deſcribed but very few of the ſpecies to which he refers, an omiſſion which we cannot ſufficiently lament, and Pliny's obſervations are not numerous. In ſhort, little was effected till the beginning of the 17th century, when Mouffet's Inſectorum ſive minimorum animalium theatrum was printed in London 1634; this work appears to have been only finiſhed by Mouffet, it having been begun in 1550, by Edward Wootton, continued by Conrad Geſner, and enriched by Thomas Penny; it is embelliſhed with wooden cuts. Aldrovand, who publiſhed in 1638, and Jonſton in 1653, were mere compilers, and added nothing new to this ſtock of knowledge. To theſe ſucceeded many figures of inſects uſed as embelliſhments to paintings of flowers, which led the artiſts as it were imperceptibly to apply themſelves to this ſtudy; in this liſt we find the names of Robert, Hoefnagel, Goedart, Merian, Schvartz, Albin, &c. Rhedi in 1668 and 1684 publiſhed his valuable works. The invention of microſcopes opened a new field totally unknown to the ancients, and among the labourers in this extenſive field we ſee the valuable names of Lewenhoek, Joblot, Hook, Needham, Malphigi, Swammerdam, Lyonet, De Geer, Baker, and the two Adams's, father and ſon, beſides many others. But in this liſt Swammerdam appears to have ſurpaſſed all his predeceſſors, and to have gained infinite fame; he was the firſt who inveſtigated the internal ſtructure of inſects, at which he acquired ſuch a preciſion and dexterity, that he could diſplay and demonſtrate the moſt minute parts of theſe ſmall animals with clearneſs and accuracy. Lyonet's work on the Larva of the Phalæna Coſſus, is beyond praiſe; and it is ſincerely to be wiſhed that his ſecond work on the Pupa of the ſame inſect, which it is ſaid was finiſhed before his death, may not long be with-held from the public. Reaumur made a rapid progreſs, not only in the anatomy but alſo in the œconomy and habits of inſects, purſuing them with unwearied attention through their ſeveral ſtates and changes. The illuſtrious Swede Baron Charles De Geer, trod in the ſame path, and excelled all that had gone before him, not only adding to the diſcoveries of Lewenhoek, but extending the anatomical reſearches of Swammerdam, uniting with theſe the objects of inveſtigation propoſed by Reaumur; and above all, digeſted the catalogue of inſects into claſſes and orders. The ſpace allotted us in this work will prevent our doing ample juſtice to the merits of all the writers on this exhauſtleſs ſubject; but we cannot paſs over the excellent work of our countryman Liſter, on Engliſh ſpiders, which to this day remains unequalled, nor the copious obſervations of that ſuperlative genius Ray, a man of inexhauſtible induſtry and perſeverance. The ſyſtematic writers are Linnæus, De Geer, Scopoli, Shultzer, Geoffroy, Gronovius, Schæffer, Fabricius, &c. and of theſe Linnæus ranks the higheſt; it was he who firſt reduced the genera and families of inſects into order in the Syſtema Naturæ, publiſhed in 1735 and 1740; and although his ſyſtem was the firſt, it yet ſtands unrivalled for clearneſs and perſpicuity. We muſt now content ourſelves with giving a bare liſt of many admirable works, ſome of which are lately publiſhed, and do honor to the ſcience, ſuch as Bonnet, Friſch, Seba, Ehret, Admiral, Wilkes, Brunnich, Leche, Leſſer, Roeſel, Drury, Harris, Sepp, Knoch, Forſter, Ernſt, Cramer, Voet, Stoll, Fueſly, Fabricius, Schrank, cum multis aliis: together with a number of elegant diſſertations of Linnæus and his pupils, publiſhed in the Amœnitates Academicæ, many of which are tranſlated by Stillingfleet, Brand and Curtis; and to theſe we would recommend our readers as affording much valuable information.

SEXES OF INSECTS, AND THE PROPAGATION OF THEIR SPECIES.

In this particular, inſects differ from all other animals, there being not only males and females of each ſpecies, but in many caſes neuters; to diſtinguiſh the ſexes of inſects, requires much ſkill and knowledge, the males in many inſtances differing ſo eſſentially from the females as not even to preſerve a ſimilarity; as in the *Lampyris noctiluca*, or glow worm, and in many ſpecies of moths, where the male is winged and the female apterous. Among the ants the neuters only are without wings. This laſt ſex is confined to thoſe inſects who live in ſocieties, as bees, waſps, ants, &c. where providence has ſo ordained, that being incapable of generation, they perform the whole buſineſs of the community, leaving the males and females to *The Propagation of their Species*; In which we find very ſingular exceptions to thoſe laws which are obſerved in the higher orders of animated beings. We have before obſerved that inſects are produced from an egg laid by the female parent, after an impregnation from the male; but in the Aphides one impregnation or union of the male and female, is ſufficient for five generations; and what is ſtill more worthy of admiration, the ſame ſpecies of Aphis which was viviparous in the ſummer, becomes oviparous in the autumn; it would be impoſſible to note here one thouſandth part of that care and attention, aſtoniſhing ſagacity, or inſtinct, with which inſects are endued for the preſervation of their young; the facts are conſtantly before us, and yet are paſſed by unnoticed and neglected.

FOOD OF INSECTS.

All animal and vegetable ſubſtances ſeem to be allotted by the Creator, for the food of inſects, and the higheſt tree has its inhabitants equally with the loweſt moſs. The root, trunk, leaves, flowers, and fruit, have each its deſtroyer, while many exiſt in the bodies of living animals, and numbers depoſit their eggs in dead and putrid carcaſes, dunghills, ſtagnant waters, &c. all of which afford a proper nouriſhment for the young offspring, even hard and dried wood, and all animal ſubſtances, ſuch as preſerved quadrupeds, birds and inſects, are ſoon deſtroyed without great care; and it is not a ſmall number who live upon other inſects; for there is no claſs of animals ſo voracious or who eat ſo much food in proportion to their ſize as inſects. In many countries they occaſion a famine, and even in our own where we are not ſo liable to their depredations, we are conſtantly exerting ourſelves to preſerve our viands, clothes, and furniture, and even our bodies, from being conſumed or annoyed by them.

MODE OF LIVING.

After giving ſome account of the food of inſects, it may not be improper to give a ſlight ſketch of that admirable proviſion adapted to the preſervation of each individual ſpecies in its infant ſtate; ſome as ſoon as they are hatched form little ſocieties, and live in a web, ſpun round the ſlender branch of a tree, which they enlarge as they increaſe in ſize; others fixed by one end to a ſmall twig ſtand almoſt erect and motionleſs, reſembling a thorn or decayed part, their colour being ſimilar; many by a delicate ſlender thread draw the leaves of a plant cloſe and tight round them, forming a neat cylindric caſe. The phalæna ſarcitella, or cloaths moth, covers itſelf with the fineſt threads of the wool on which it is feeding, enlarging its houſe as it grows bigger; and if you fix it ſucceſſively upon different coloured cloths, it becomes party-coloured like the jacket of an harlequin. The cicada ſpumaria, or froghopper, emits a frothy matter in which it lies concealed, and the larvæ of the phryganeæ, who ſeek their food in the bottom of ponds and rivers, form little ſtrong hollow tubes with ſtones, ſhells, or ſmall particles of wood, which they line with a ſilky ſubſtance, and by that means eſcape falling a prey to many ſpecies of fiſh.

USES OF INSECTS.

Reaſon and obſervation daily teach us that nothing was created in vain, but that every living creature has its uſe, although that uſe may not always come within the ſphere of our capacity, and it is probable that the uſes of numberleſs ſpecies of inſects may never be made known to us; yet we have every reaſon to believe that theſe minute beings are of very conſiderable importance in the grand ſcale of creation, that each of them has its proper buſineſs aſſigned to it in the œconomy and police of nature, whereby they tranſact the greateſt things, and though gradually and ſlowly, yet by their number they effect what would appear to exceed all expectation and belief. It is by their means that a proper proportion and equilibrium are preſerved in vegetables by deſtroying many which are inacceſſible to large animals; happily ſome clear the ſurface of the earth, of impure and ſuperfluous, ſome the air of fœtid and putrid matters, and others muddy and ſtagnating waters of heterogeneous and filthy mixtures. The labours of the ſilk-worm and bee are little attended to in general, becauſe they are frequently before us; but can we without gratitude reflect that in this ſmall iſland 50,000 people are daily maintained by the delicate and curious workmanſhip of one little groveling worm. The medicinal properties of honey, and the numerous uſes to which wax is applied, have made them conſiderable objects of commerce. The meloe veſicatorius, or cantharides of the ſhops, is alſo of ſovereign utility in the hands of the phyſicians; as is the cochineal inſect to the dyer. The labour of another inſect (cynips) produces the gall ſo eſſential in making ink; but this is an exhauſtleſs ſubject; and therefore we ſhall, agreeable to our plan, proceed to their.

DESTRUCTIVE PROPERTIES.

Happily in our climate we are fully exempt from many of the moſt terrible deſtroyers: we are totally unacquainted with the gryllus migratorius, a ſpecies of locuſt, which ſome years ago came in ſuch immenſe numbers out of Tartary as to darken the air, laying waſte almoſt all Europe; the muſca hordei, which is ſaid by Linnæus to deſtroy one fifth part of the corn in the granaries of Sweden amounting annually to 100,000 tons. The phalæna calamitoſa and graminis, in ſome countries lay waſte the meadow lands ſo as to render the hay not worth cutting. The tenthredo pini ſtrips whole plantations of firs of their leaves, and by that means haſtens their death; and ſurely we ought to be peculiarly thankful for our ignorance of the Heſſian fly, that for eleven years paſt has been increaſing in America, totally deſtroying all the wheat. We are indeed much plagued in our cities and large towns, with the cimex lectularius, or bed bug, the common flea, and the louſe which ſwarm in the heads of children; the blatta orientalis is very troubleſome in our kitchens; but the inſect moſt terrible in its effects is the acarus ſiro, which inſinuates itſelf under the cuticle, where it increaſes to an immenſe degree ulcerating and producing a leprous irruption called the itch. Many ſpecies of the tabani, gnats, &c. annoy us in the fields with their pungent bite, as do the conops calcitrans, an inſect much reſembling the common fly in our houſes.

Spiders alſo are very unpleaſant companions in our houſes, although they leſſen the quantity of the houſe fly in the autumn when it covers all our victuals and ſweetmeats in ſuch vaſt numbers; the phalæna granella deſtroys the corn in our granaries, and the eggs of the tenebrio molitor, produce the meal worm in flour. Cheeſe is deſtroyed in quantity by acari, or mites, and the larvæ of the muſca putris; our woollen furniture and cloaths without great care fall a ſacrifice to a ſmall moth, as do our furs to the dermeſtes pellio. Our fruit trees are frequently ſpoiled of their foliage by the larvæ of various moths, and our cabbages totally deſtroyed by the caterpillars of the white butterfly; but were we to enumerate the damage done by each particular ſpecies, it would fill a volume: we ſhall however obſerve that the inſects which deſtroy the turnep in ſome counties and the hop in others, neither of which appear to be properly defined, are the moſt pernicious inſects the farmers in this country have to encounter. Our oxen and cows ſuffer much from the oeſtrus bovinus, which is nouriſhed in their backs, living there the whole winter. The oeſtrus hæmmorhoidalis, or bot, is bred in the inteſtines of horſes to which it enters by the rectum; the oeſtrus ovis leaves its eggs in the noſtrils of ſheep, the maggots of which lodge the whole winter in the cavity of the forehead often occaſioning death. The hippoboſea equina, or foreſt-fly is very troubleſome to horſes, who have alſo a ſpecies of louſe which emaciates them by degrees. Birds are all infeſted with lice, each genus having a peculiar one; our domeſtic poultry, if they rooſt for a conſiderable time in a confined place, ſuffer very much from them, the old ones droop, but the young ones die; pepper is in this caſe the beſt antidote. Crabs are great deſtroyers of fiſh in rivers, lakes, &c. as are the dytiſci in ponds. The oniſcus entomon is a terrible enemy to the herring, and even that enormous animal the whale, is prayed upon by the oniſcus ceti. The inſects which deſtroy other inſects are innumerable, and therefore we muſt paſs them over, with only obſerving that the breeders of bees ſhould be very careful to guard them againſt the phalæna melonella, which eats the honey comb, and from hornets and waſps their moſt deſtructive enemies.

METAMORPHOSES OF INSECTS.

This aſtoniſhing property ſeems peculiar to inſects; for all, except thoſe of the aptera claſs, are continually undergoing ſome transformation; this circumſtance while it increaſes the number of objects, renders the ſtudy of the ſcience more difficult, becauſe the ſame individual in one ſtate bears no reſemblance to itſelf in another ſtate; their firſt change is from the egg to the *larva*, caterpillar or maggot, then into the *pupa*, chryſalis or aurelia, and laſtly into the *imago*, fly, or perfect ſtate. Linnæus was the firſt who applied the term *larva*, which ſignifies maſked, to the firſt ſtate of an inſect, becauſe he thought it fully expreſſed its ſituation, as its true appearance then lay concealed; Swammerdam having demonſtrated that the butterfly with its wings, exiſts in the caterpillar, though its reſemblance is very imperfect. Inſects in this ſtate feed and increaſe in ſize, frequently changing their ſkin: when they are full fed they ſeek out a convenient place, roving ſometimes for days, wherein to make their ſecond change, formerly called chryſalis and aurelia from the elegant ſpots like gold on ſome of the butterflies; now named *pupa*, from the likeneſs they bear to an infant in ſwaddling cloaths. The modes in which this is performed are almoſt as numerous as inſects themſelves, and in this ſtate all, but the hemiptera claſs, take no nouriſhment. After a certain time, which is often accelerated or retarded by the ſeaſons, the inſect breaks its outward covering and burſts forth as it were into new life, in glory and ſplendour; this laſt production is called by the ſame author its *imago* or perfect ſtate; it appears at firſt, moiſt, tender, and its wings rumpled together, in a few minutes it becomes dry, its antennà appear, the wings ſhoot forth, its ſtrength increaſes, and all its beauty and luſtre become apparent; it now undergoes no more transformations, but ſporting in the air ſeeks out its mate; and, after propagating its ſpecies, dies. It is here however worthy of remark, that the ephemeron, gnat, &c. who live through and undergo their two firſt changes in the water, in their laſt or fly ſtate, infallibly loſe their lives if they chance to fall into that element. As the *pupa* of inſects differ much in ſhape, they have been named,

Coarctata, when round, and as it were turned without any reſemblance to the inſect incloſed, as in the diptera.

Obtecta, when it conſiſts of two parts, one of which incloſes the head and thorax, and the other the abdomen.

Incompleta, in this they have wings and feet, but are not capable of moving them, as in the hymenoptera.

Semicompleta, theſe walk or run, but have only rudiments of wings.

Completa, in which they immediately obtain the form of the inſect without undergoing any further change as in the aptera, the flea excepted. The bed bug belongs to this claſs.

The ſpider undergoes frequent transformations, but it is only in the colour of its ſkin; cruſtaceous inſects, as crabs, lobſters, &c. yearly caſt their ſhells, as their growth would otherwiſe be impeded. The ſcolopendri, when young, have fewer feet than when they are full grown.

METHOD OF COLLECTING AND PRESERVING INSECTS.

Thoſe who would wiſh to acquire a good collection of inſects muſt not ſhrink from a little trouble, but be conſtantly on the foot for that purpoſe. Three kinds of net are neceſſary, viz. the forceps net, a hoop net, and a large folding net, made like thoſe uſed for batfowling; all of which ſhould be made of gauze, with the ſtiffening taken out. The firſt will be found convenient for taking the inſects of the hymenoptera claſs, or thoſe armed with ſtings, the ſecond is beſt adapted to water inſects, and the laſt for butterflies and moths, in the handling of which much care is neceſſary, ſo as not to rub off the curious ſcales or feathers with which their wings are covered; they are beſt killed by ſqueezing them with the finger and thumb between the wings while in the net, and then ſticking a pin through the body, by which means they may be immediately placed in the pocket box, which ſhould be made of thin deal, and lined at top and bottom with cork. Butterflies are on the wing during the day in fine weather, and are to be found in various ſituations according to their kinds, many of the moſt beautiful, frequent woods, they may alſo be caught in an evening while aſleep on different plants. Moths in general fly only in the twilight after ſun ſet, and therefore require a keener eye; but the beſt way of having them in perfection is to breed them from the caterpillars, which may be procured by ſpreading a large ſheet under the trees, and beating them with a long pole; they are then to be placed in a ſquare box with canvas ſides like a meat ſafe, the bottom of which ſhould be covered 3 or 4 inches deep with light earth kept tolerably moiſt, care being had to ſupply them with the plants on which they are found, which will keep freſh for ſeveral days if placed in phials of water; when the time of change approaches they leave off eating, and either go into the earth to perfect their change, or ſpin themſelves webs againſt the ſides of the box, wanting no further care nor attention. Many curious inſects may often be found on the ſheet by the foregoing mode of beating; if a ſheet is not at hand, a large piece of paſteboard is a good ſubſtitute, which the collector can hold in one hand while he beats with the other. The pupa of many moths may be found by digging at the roots of trees. Underwoods, particularly thoſe which are cut down every 5 or 7 years, afford the greateſt variety of inſects; but it is neceſſary that the collector ſhould examine putrid bodies, dung of animals, rotten wood, ditches, pools, &c. if he wiſhes to obtain an extenſive knowledge or acquire a large collection, he will alſo find many inſects under ſtones in moiſt and humid places. Bees waſps, &c. are killed by ſpirits of turpentine, and the whole tribe of beetles or cruſtaceous inſects by immerſion in ſcalding water. The collector ſhould always be furniſhed with a pincuſhion, well ſtored with pins of different ſizes and a number of pill boxes, or ſmall phials. To preſerve them properly, it is neceſſary to place them in drawers or boxes lined with cork, and covered with glaſs, which ſhould be made to ſhut as tight as poſſible, and a ſmall compartment or two ſhould be contrived to hold camphire, which is a good preſervative.

DEFINITION OF AN INSECT.

Linnæus has clearly proved that of all animals thoſe only which he has called inſects, are furniſhed with antennæ, that they are deſtitute of bones, but covered with ſkin externally hard, which like a compleat ſuit of armour preſerves them from injury, being of immenſe ſtrength in compariſon to its ſize. All inſects have ſix or more feet, and they reſpire through pores placed on the ſides of their bodies, which are termed ſpiracula; but the antennæ placed on the fore part of the head conſtitute the principal diſtinction. They are jointed and moveable, in which they differ from the horns of all other animals. Before Linnæus pointed out theſe eſſential characters, the crab, which is a true inſect, was claſſed with fiſh, and the hippocampus, a fiſh, was claſſed with inſects. The meduſa, cockle, earth worm, even zoophites, and other claſſes of worms, were likewiſe confounded with them.

SCIENTIFIC DESCRIPTION.

The body of an inſect is divided into a *head*, *trunk*, *abdomen*, and *limbs*. *Caput*, the head, is attached to the trunk by an articulation or joint; it is furniſhed with eyes, antennæ, and in moſt caſes a mouth, but is deſtitute of brains, noſtrils or ears. The eyes are moſtly two in number, without eyelids, and are either ſimple or compound, conſiſting of one or more lenſes, and are the organs of viſion as in other animals. Inſects in general have two antennæ compoſed of an indefinite number of articulations; they differ from the tentacula of the vermes in being cruſtaceous; and are eaſily diſtinguiſhed by their ſituation from the palpi of inſects, which are generally more numerous, and always placed near the mouth. As the antennæ are a very diſtinguiſhing feature in many genera, it will be proper to explain their different forms; they are called

Setaceous, when they gradually taper from the baſe, to the point, like a briſtle.

Filiformes, or thread ſhaped, when of equal thickneſs throughout.

Moniliformes, compoſed of globular joints, reſembling a ſtring of beads.

Enſiformes, ſhaped ſomething like a ſword.

Clavatæ, club ſhaped, when they gradually increaſe in ſize towards the extremity.

Capitatæ, like clavatæ, but the laſt articulation larger and rounder, forming a kind of knob.

Fiſſiles, are capitatæ, but the capitulum or knob is divided longitudinally into 3 or 4 plates, or laminæ.

Perfoliatæ, are alſo like capitatæ, but with the capitulum horizontally divided.

Serratæ, notched like the teeth of a ſaw.

Pectinatæ, like a comb or feather.

Filatæ, ſimple without a lateral hair.

Ariſtatæ, ſuch as have a lateral hair, either naked or furniſhed with leſſer hairs.

Plumatæ, having a lateral feather.

They are termed *breviores*, when ſhorter than the body, *mediocres* when of equal length, and *longiores*, when longer than the body. The *palpi*, or feelers, ſo firſt named by Linnæus, reſemble thread ſhaped, articulated moveable antennæ, from which they differ in being naked, ſhort, and always placed about the mouth: they are moſt commonly four in number, ſometimes ſix, and in a few inſtances only two.

Os, the mouth, is generally placed on the anterior part of the head, extending ſomewhat downwards, ſometimes in the breaſt, and is furniſhed with a roſtrum, or proboſcis, an upper lip, jaws, teeth, tongue and palate; ſome inſects indeed have no mouth.

Maxillæ, the jaws, are two, and ſometimes four in number, placed horizontally, the inner edge of which in ſome inſects is ſerrated, or furniſhed with teeth.

Lingua, the tongue, is either taper and ſpiral, fleſhy, reſembling a proboſcis, or tubular.

Labium ſuperius, the upper lip, is ſituate above the jaws.

Stemmata, or gems, are three bright convex ſpots, or tubercules, placed upon the crown or upper part of the head.

Truncus, the trunk, is that part of the body, ſituate between the head and abdomen, the upper part is called the *thorax*; to the poſterior part of which the ſcutellum, or eſcutcheon, is annexed. This is frequently triangular, and appears to be divided from the thorax at its baſe by an intervening ſuture, and projects between the elytra, from the interior margin of each a piece appears to be cut out for its inſertion. The under part of the trunk, is called the ſternum, or breaſt, and to this part the feet are generally fixed.

Abdomen, this is the hinder part of the inſect, it is diſtinct from the thorax, and contains the ſtomach, inteſtines, and viſcera: it is compoſed of a number of annular ſegments, which are pierced in the ſides with ſpiracula or pores that ſupply the want of lungs, the upper part of the abdomen is called *tergum*, or the back, the under *venter*, or belly, which is terminated by the anus.

Artus, the limbs, are the tail, feet, and in many ſubjects, the wings alſo.

Pedes, the feet, are compoſed of three joints, the firſt of which is generally the thickeſt, and is called *femur*, or thigh; the ſecond, which is commonly of the ſame ſize throughout, is named *tibia*, or leg; and the third, which is divided into leſſer joints, is called *tarſis*, or foot; and theſe are terminated by *ungues*, nails; ſome indeed have a kind of hand, chela, with a moveable thumb; the hinder feet are formed for different movements, as running (curſorii) leaping, (ſaltatorii) ſwimming, (natatorii); thoſe feet which have no claws, are termed *mutici*.

Alæ, wings, are curious inſtruments by which they are enabled to fly; theſe are membraneous and undivided, except in one genus of moths Alucitæ.

Moſt inſects have four wings, but the claſs diptera and the coccus have only two. The wing is divided into its ſuperior and inferior ſurfaces; the anterior part is the thick margin nearly in a line with the head when the wings are extended; the poſterior, the ſlender margin next the anus; the exterior part, is that towards the outer edge; the interior, that next the body; they are called *plicatiles*, when folded up, while the inſect is at reſt, as in the *forficula*; and *planæ* when they are incapable of being folded, as in the papiliones.

Erectæ, ſuch as have their ſuperior ſurfaces brought in contact, when the inſect is at reſt, as in the ephemera, &c.

Patentes, which remain horizontally, as in the phalæna geometra.

Incumbentes, theſe cover horizontally the ſuperior part of the abdomen.

Deflexæ, the outer edges declining towards the ſides, and the inner edges uniting above the abdomen, like the ridge of a houſe.

Reverſæ, is the ſame as deflexæ, with this difference, that the under wings project conſiderably from under the upper ones.

Dentatæ, the edges of theſe are ſerrated or ſcolloped.

Caudatæ, theſe have one or more projections in the hinder wings like tails.

Reticulatæ, when the veins or membranes croſs one another ſo as to reſemble net work.

The colours of the wings are diſtinguiſhed by different names according to their figure, as punctæ, dots; maculæ, ſpots; faſciæ, bands; ſtrigæ, ſtreaks; which are ſlender faſciæ; and lineæ, lines; which are longitudinally extended; ocellus or eye, is a round ſpot containing a leſſer ſpot within it; ſtigma, is a kidney ſhaped ſpot almoſt univerſal in the wings of the phalæna noctua. Stigmata, is another term uſed by Linæus to ſignify the ſpot or anaſtamoſis, in the middle of the wing near the anterior margin, conſpicuous in moſt of the hymenoptera and neuroptera, and alſo in the coleoptera.

Elytron, plural Elytra, are the upper wings, or rather wing caſes, two in number, of a cruſtaceous ſubſtance, extended when the inſect flies, but ſhut when it reſts, forming a longitudinal ſuture down the back, and covering the wings. The elytra are variouſly diſtinguiſhed, and are termed,

Abbreviata, when ſhorter than the abdomen.

Truncata, are alſo ſhorter than the abdomen, but terminate in a right line at their extremity.

Faſtigiata, are of equal or greater length than the abdomen, but terminate in a tranſverſe line.

Serrata, when the exterior margin towards the apex is notched, or ſerrated.

Spinoſa, when the ſurface is covered with ſharp points, or prickles.

Scabra, when the ſurface is rough like a file.

Striata, when marked with ſlender longitudinal furrows.

Porcata, when marked with elevated longitudinal ridges.

Sulcata, when furrowed, or deeply channelled.

Punctuata, when marked with concave, or convex ſpots.

Hemelytra, are ſo called, when the ſuperior wings, or caſes, are harder than the wings, but yet ſofter than the elytra, and are either totally ſo as in the grylli, or partially ſo as in the notonecta, nepa, cimeces, &c. The ſecond order, or hemiptera, contains all the inſects of this claſs.

Halteres poiſers, or balancers, are little heads placed on a pedicle, or foot ſtalk, and are ſituate in the thorax behind and under the wings of the ſixth, or diptera claſs, which have only two wings, and are ſuppoſed to act as balances, to keep the body in equilibrio, when they fly.

Cauda, the tail, differs in different inſects, and is either ſimple or furniſhed with various appendages; it is *Triſeta*, conſiſting of three briſtles in the ephemera, *Furcata*; forked in the podura; *Forcipata*, like pincers in the forficula; *Folioſa*, reſembling a leaf in the blatta and ſome cancri; *Telifera*, armed with a ſting, as in the ſcorpion and panorpa; *Aculeus* is alſo another kind of ſting, concealed within a fine tube, which inſtills a poiſon at the time it wounds, as in the bees, hornets, waſps, &c.

To render the foregoing deſcription more uſeful, and explicit, we have added an explanatory plate.

PART II.

CLASSIFICATION ACCORDING TO THE LINNÆAN SYSTEM.

Linnæus has divided inſects into ſeven orders, ſix of them from the nature and number of their wings, and the ſeventh from their being deſtitute of wings.

The firſt order he has named *Coleoptera*, from κολεὸς, *a ſheath*, and πλεϱὸν, *a wing*; and this order comprehends all that claſs of inſects, called beetles, which have hard cruſtaceous elytra, that ſhut together and cover the wings, forming a longitudinal ſuture down the back. The elytra in moſt inſects cover the abdomen entirely, as in the cock-chaffers; but in others but partially, as in the ear-wig, &c.

Order 2. *Hemiptera*, from ἡμισυ, *half*, and πλεϱὸν, *a wing*. Theſe have their elytra, or upper wings, but half cruſtaceous, and half membranaceous, not forming a longitudinal ſuture, but incumbent on each other.

Order 3. *Lepidoptera*, from λεπὶς, *a ſcale*, and πλερον, *a wing*. Theſe have four membranaceous wings, imbricated or covered with ſcales, like powder or meal.

Order 4. *Neuroptera*, from νεῦρὸν, *a nerve*, and πλερὸν, *a wing*. Theſe have four membranaceous, tranſparent, naked wings, generally reticulated with veins, or nerves; tail unarmed, or without a ſting.

Order 5. *Hymenoptera*, from ομὴν, *a membrane*, and πλερὸν, *a wing*. Theſe have four membranaceous wings, tail armed with a ſting.

Order 6. *Diptera*, from δύω, *two*, and πλερὸν, *a wing*. Two wings only, but finiſhed with halteres or poiſers, inſtead of under wings.

Order 7. *Aptera*, from ἀ, *without*, and πλερὸν, *a wing*. Having no wings, as in the ſpider, &c.

Theſe Orders are ſubdivided by Linnæus, in a table under the title of *Characteres Inſectorum*; but as theſe characters are again repeated as the diſtinguiſhing mark of each genus, it is quite unneceſſary to give them here.

ORDER I. INSECTA COLEOPTERA.

This Order is diſtinguiſhed, by the hard cruſtaceous elytra, which cover and protect the wings, and contains 30 diſtinct genera.

Genus 1. SCARABÆUS, or beetle. The antennæ of which terminate in a kind of club, which is divided longitudinally into plates or laminæ, from 2 to 7 in number, the tibiæ of the firſt pair of legs are armed with ſpines or teeth.

This genus contains three diviſions or families.

1ſt. Thoſe in which the thorax is armed with horns.

2d. Thoſe which have horns on the head only.

3d. Thoſe which have head and thorax, both ſimple or without horns.

Genus 2. LUCANUS, or ſtag beetle; the antennæ of the Lucanus terminate in a club or knob, but differs from the preceding genus in its being compreſſed or flattened on one ſide, which part is divided into ſhort plates or laminæ; ſome of this genus have the antennæ bent in the middle, forming a kind of elbow. The maxillæ or jaws, are ſtrong, advanced before the head, and are armed with teeth.

Genus 3. DERMESTES. Antennæ ending in a perfoliated club or head of an oval form, divided into horizontal plates, which appear to be united together by a ſmall ſtalk paſſing through their center; the three extreme articulations are larger than the others: the thorax is convex, and ſlightly margined: the head is bent inwards, and as it were concealed under the thorax.

Genus 4. PTINUS. Antennæ filiform or thread ſhaped, the exterior articulations longer than the others. The thorax nearly round, with a margin into which the head is received or drawn back.

Genus 5. HISTER. The firſt articulation of the antennæ is compreſſed and curved: the laſt or terminating one appears to be a ſolid knob: the head is drawn within the body, ſo that the jaws, which reſemble a forceps, are only viſible: the elytra are ſhorter than the body, and the fore legs are dentated as in the ſcarabæus.

Genus 6. GYRINUS. Antennæ club formed, ſtiff and ſhorter than the head. It has four eyes, two on the upper, and two on the under ſide the head.

Genus 7. BYRRHUS. Antennæ clubformed, terminating in a capitulum or knob, which is of an oval form, rather flattened, and almoſt ſolid.

Genus 8. SILPHA. Antennæ ſmall at their baſe, and gradually increaſing in thickneſs to their extremity; the elytra have a margin, the head prominent, and the thorax rather flattened, with a margin.

Genus 9. CASSIDA, or tortoiſe beetle. Antennæ nearly of equal thickneſs, but increaſe in ſize towards the extremity. Elytra has a broad margin, the thorax is flat and margined, forming a kind of ſhield for the head, which is entirely concealed under it.

Genus 10. COCCINELLA. Antennæ are ſubclavated, or increaſing a little in thickneſs towards the end, the laſt joint appears as if the end was chopped off. The palpi are club-formed, with the laſt articulation, ſhaped like a heart. The body is hemiſpherical, thorax and elytra margined, abdomen and belly flat.

This genus is ſubdivided into families, from the colour of the elytra, and of the ſpots with which they are adorned.

1. Thoſe with red or yellow elytra, and black ſpots.
2. Thoſe with white ſpots on a red or yellow ground.
3. Thoſe with black elytra and red ſpots.
4. Thoſe with black elytra, and white or yellow ſpots.

Genus 11. CHRYSOMELA. Antennæ moniliformes, or compoſed of little globular articulations, increaſing in ſize towards the extremity. Neither thorax nor elytra have any margin. This genus is divided into five families, viz.

1. Corpore ovato, whoſe bodies are of an oval form; many of which reſemble the coccinellæ.

2. Saltatoriæ, whoſe hinder thighs are much thicker than the other, and are made for leaping.

3. Corpore cylindrico. The bodies of theſe are of a cylindric form.

4. Corpore oblongo, Thorace anguſtiore. In theſe the body is oblong, and the thorax narrower than the abdomen.

5. Elongatæ. Theſe are long and of a ſlender make, and indeed bear little affinity to either of the others.

Genus 12. HISPA. Antennæ fuſiformes, increaſing gradually in ſize from each extremity towards the middle; they are ſituate between the eyes, and are placed ſo near each other at the baſe, that they ſeem to ariſe from one point. The thorax and elytra are generally covered with ſpines.

Genus 13. BRUCHUS. Antennæ filiformes, ſenſim craſſiores, that is of equal ſize, but growing thicker towards the extremity; this was ſurely an overſight in Linnæus, as it is contradictory; the antennæ of the Linnean Bruchi, do gradually increaſe in ſize towards the extremity, the head projects forward ſomething like a roſtrum. The thorax is marginated, and the elytra are ſhorter than the abdomen, and rounded at the apex.

Genus 14. CURCULIO. Antennæ ſubclavatæ, roſtrum inſidentes, or ſubclavated, and ſeated in a roſtrum or proboſcis, which is of a horny ſubſtance; and in ſome ſpecies prominent, in others inflex or bent under the thorax. This genus is divided into the following families.

1. Longiroſtres femoribus ſimplicibus. Roſtrum or beak longer than the thorax, and whoſe thighs are ſimple, without teeth or ſpines.

2. Longiroſtres ſaltatorii femoribus poſticis craſſis. Roſtrum longer than the thorax, hinder thighs large and made for leaping.

3. Longiroſtres femoribus dentatis. Roſtrum longer than the thorax, and the thighs dentated.

4. Breviroſtres femoribus dentatis. Roſtrum ſhorter than the thorax, and the thighs dentated.

3. Breviroſtres femoribus muticis. Roſtrum ſhorter than the thorax, and the thighs ſimple.

Genus 15. ATTELLABUS. The head of the attellabus is broader in the fore part, and tapers gradually from the eyes to the thorax. Antennæ are thicker towards the extremity than at the baſe; ſome of this genus come ſo near the curculiones, as often to be miſtaken for them.

Genus 16. CERAMBYX. Antennæ compoſed of oblong articulations, which gradually diminiſh in ſize towards the extremity. The thorax is either armed with ſpines or gibbous, made uneven by ſmall elevations. The elytra are narrow and of equal breadth throughout. This genus is divided into ſections from the form of its thorax, and that part being armed or not armed with ſpines.

1. Thorace ſpinis lateralibus mobilibus. Thorax armed on each ſide with moveable ſpines.

2. Thorace marginato dentibus lateralibus. Thorax margined, and ſides armed with teeth or ſpines.

3. Thorace rotundato, ſpinis fixis lateralibus mucronato. Thorax round and armed with fixed ſpines.

4. Thorace inermi ſubcylindrico. Thorax nearly cylindrical and unarmed.

5. Thorace inermi ſubrotundo ſive ex globoſo depreſſo. Thorax roundiſh, reſembling a globe flattened on the upper ſide.

Genus 17. LEPTURA. Antennæ briſtle ſhaped, elytra diminiſhing in breadth towards the apex; thorax roundiſh and of a ſlender make.

This genus is divided into two families.

1ſt. Thorace ovato ſivè entrorſum, oblongiuſculo anguſtiore, elytris apice truncatis. Thorax ovate or broader at the apex, than were joined to the head, the elytra cut off in a right line at their extremity.

2d. Thorace ſubgloboſo, nec antice attenuato, elytris, apice obtuſis, nec truncatis. Thorax nearly globular, and elytra obtuſe at the extremities.

Genus 18. NECYDALIS. Antennæ briſtle ſhaped; this genus is divided into two ſections.

1ſt. The elytra-ſhorter than the wings and abdomen, wings not folded under the elytra, as in the forficula.

2d. Elytra as long as the body, but narrower, contracting to a point, or awl ſhaped.

Genus 19. LAMPYRIS. Antennæ of equal thickneſs throughout Elytra, weak and flexible, thorax flat; and ſemiorbicular, ſurrounding and concealing the head. The ſegments of the abdomen, terminate on each ſide in papillæ, or little appendices, which are bent up towards the elytra, and in part cover one another; females in general are apterous.

Genus 20. CANTHARIS. Antennæ ſhaped like a briſtle; thorax margined, and ſhorter than the head. Elytra flexible; ſides of the abdomen, as in the preceding genus; there are two families.

1ſt. Thorace depreſſo, in theſe the thorax is flat and broad.

2d. Thorace teretiuſculo; thorax rounded in the ſides and narrow.

Genus 21. ELATER. Antennæ briſtle ſhaped; this genus is diſtinguiſhed by an elaſtic ſpring, or ſpine, which projects from the hinder extremity of the breaſt, or under ſide of the thorax, by which means the inſect makes a very ſingular leap, different from all other inſects; there is alſo a groove or cavity, ſcooped out of the under ſide of the head, in which the antennæ are lodged.

Genus 22. **CICINDELA.** Antennæ tapering to the extremity, maxillæ, or jaws armed with teeth, and project forwards, the eyes prominent, thorax roundiſh and margined.

Genus 23. **BUPRESTIS.** Antennæ briſtly, and the length of the thorax, the head is half drawn back within the thorax, they are divided into three families.

1ſt, In which the elytra decline towards the ſides, being much elevated at the ſuture, particularly near the baſe.

2d, Elytra ſerrated or armed with ſhort ſpines near their extremity.

3d, Elytra whole and intire.

Genus 24. **DYTISCUS.** Antennæ { ſetaceous, or increaſing in ſize, having a perfoliated capitulum.

They are divided into ſections.

1ſt. Antennæ perfoliated
2d. Antennæ ſetaceous } hinder feet hairy, natatorii, and armed with ſmall claws.

Genus 25. **CARABUS.** Antennæ briſtle ſhaped, thorax in the form of a heart, with the point cut off. The elytra are margined, a conſiderable lamina or knob, fixed at the baſe of the hinder thighs appear conſtant in this genus, and therefore ought to be noticed. Linnæus divides them into two families, merely from their ſize; viz. majores et minores.

Genus 26. **TENEBRIO.** Antennæ moniliform, or like a ſtring of beads, the laſt articulation rounder than the others. Head ſtretched forward, and elytra ſtiff; this genus is divided into families, the firſt containing thoſe which have wings, and the other in which the elytra are united, or without a longitudinal ſuture.

Genus 27. **MELŒ.** Antennæ moniliform, but the laſt joint oval, thorax roundiſh. Elytra ſoft and flexible, head inflected and gibbous. Theſe are divided into two families,

1ſt. With ſhort elytra, and no wings.

2d. Elytra the length of the body, and covering the wings.

Genus 28. **MORDELLA.** Antennæ filiform, and ſerrated. Head deflected or bent under the neck, elytra are curved or incline downwards towards their point, palpi compreſſed, clubbed, and obliquely truncated. A broad lamina is ſeated at the baſe of the abdomen, before the thighs.

Genus 29. **STAPHYLINUS.** Antennæ moniliform, elytra not half the length of the abdomen, wings folded up, and concealed under the elytra. The tail or extremity of the abdomen is ſimple, not being armed as in the following genus, but furniſhed with two oblong veſicles, which the inſect can ſhoot out, or retract at pleaſure.

Genus 30. **FORCICULA,** or Earwig. Antennæ ſetaceous, elytra much ſhorter than the abdomen, the wings are folded and covered by the elytra, the extremity of the abdomen is armed with a kind of forceps.

ORDER II.

INSECTA HEMIPTERA.

The mouth and proboſcis of the inſects which compoſe this order, are inflected or bent inwards, towards the breaſt.

The wings are of a ſubſtance between the cruſtaceous and membranaceous, not ſo hard and ſtrong as the firſt, but more ſo, than the latter; the upper wings are ſemi-coriaceous, and do not meet in a longitudinal ſuture, as in the coleoptera, but have ſome part of their interior margin croſſed, or laid one over another, above the abdomen. This order contains twelve genera.

Genus 31. **BLATTA.** Antennæ briſtle ſhaped, head inflected, elytra and wings extended, ſmooth and ſemi-coriaceous, or of a ſubſtance reſembling vellum. The thorax is flattiſh, orbicular and margined. The feet made for running. The abdomen is terminated by two little appendices, or horns.

Genus 32. **MANTIS.** Antennæ ſetaceous, head unſteady, in conſtant motion, ſlightly attached to the thorax, mouth armed with jaws, and furniſhed with palpi. Wings membranaceous wrapped round the body, the under ones folded. The thorax is narrow, extended to a conſiderable length, and of equal ſize throughout. The firſt pair of feet are compreſſed, armed on the under ſide with teeth like a ſaw, and terminated by a ſingle nail, or crotchet, the four hinder ones are formed for ſlow, rather than quick motion.

Genus 33. **GRYLLUS.** Antennæ in ſome briſtle ſhaped, in others filiform. Head inflected, armed with jaws, and furniſhed with palpi. Wings declined downwards, and wrapped round the ſides of the body; the under ones are folded up, ſo as to be concealed under the elytra, all the feet are armed with two nails or crotchets, the hind ones are formed for leaping. This genus is divided into five families.

1. Acridæ, head conic, longer than the thorax, antennæ ſword ſhaped.

2. Bullæ. Thorax elevated in the middle, antennæ ſhorter than the thorax, and filiform.

3. Achetæ, have two ſetæ or briſtles ſituate above the extremity of the abdomen.

4. Tetigoniæ, the abdomen of the females furniſhed with a tube, through which they depoſit their eggs: antennæ of both ſexes ſetaceous.

5. Locuſtæ, antennæ filiform, abdomen without the tube.

Genus 34. **FULGORA.** The fore part of the head is drawn out, extended and empty, antennæ, placed beneath the eyes of two articulations, whereof the exterior is larger, and of a globular form, the roſtrum is inflected or bent inwards under the body, the feet are formed for walking; in this circumſtance, it differs from the following Genus, with which it was formerly confounded.

Genus 35. **CICADA.** Antennæ briſtle ſhaped, roſtrum bent under the breaſt, four membranaceous wings, declining along the ſides of the body, feet in ſome formed for leaping, in others for walking, or creeping; they are divided into five families.

1ſt. Foliaciæ, thorax compreſſed, membranaceous, and larger than the body.

2d. Cruciatæ, which have the thorax armed on each ſide, with a horn or ſpine.

3d. Maniferæ. Feet not made for leaping.

4th. Ranatræ, feet ſaltatorii, the hinder ones made for leaping.

5th. Deflexæ. Wings wrapped round the ſides of the body.

Genus 36. **NOTONECTA.** Antennæ ſhorter than the thorax, roſtrum inflected, four wings folded croſſwiſe, and coriaceous from the baſe, to their middle hind feet, hairy and formed for ſwimming.

Genus 37. **NEPA.** Antennæ none, roſtrum bent inwards, four wings folded croſſwiſe, anterior parts coriaceous; two fore feet reſemble the claws of a crab; the four others formed for walking. Geoffroy is of opinion, that the fore feet are the antennæ of this inſect.

Genus 38. **CIMEX.** Antennæ longer than the thorax, roſtrum inflected, wings folded croſſwiſe, upper ones coriaceous from the baſe, to the middle, back flat, thorax margined, and feet formed for running; they are divided into eleven families.

1. Apteri, theſe are without wings.

2. Scutellati, in which the ſcutellum or eſcutcheon, is extended ſo far as to cover the abdomen and wings.

3. Coleoptrati. Elytra coriaceous, not becoming membranaceous towards their extremity, as in the other cimices.

4. Membranacei, elytra membranaceous, very much depreſſed, like a leaf.

5. Spinoſi, thorax armed on each ſide, with a ſpine.

6. Rotundati, oval ſhaped, without ſpines on the thorax.

7. Seticornes. Antennæ like a briſtle towards the point.

8. Oblongi, of an oblong figure.

9. Antennæ, ſetaceous, and as long as the body.

10. Spinipedes, thighs armed with ſpines.

11. Lineares, body remarkably long and narrow.

Genus 39. **APHIS.** Antennæ longer than the thorax, roſtrum bent inwards, four erect wings or apterous, feet made for walking, generally two horns or ſpines, at the end of the abdomen.

Genus 40. **CHERMES.** Antennæ longer than the thorax, roſtrum placed under the breaſt, wings declined along the ſides of the abdomen, thorax gibbous, and feet made for leaping.

Genus 41. **COCCUS.** Roſtrum ſituate in the breaſt, hinder part of the abdomen briſtly, males two erect wings, females apterous.

Genus 42. **THRIPS.** Antennæ as long as the thorax, roſtrum obſcure or ſcarce perceptible, body ſlender, and of equal thickneſs, abdomen bent downwards.

ORDER III.

INSECTA LEPIDOPTERA.

The inſects which compoſe this order, are the moſt delicate, elegant and beautiful of all the different genera; they have four wings covered with a farinaceous powder, or a kind of ſcales, diſpoſed in rows, nearly in the ſame manner as tiles are laid upon the roofs of houſes; the various colours that adorn the wings are formed by theſe ſcales, which under a microſcope, appear like an elegant and beautiful carpet; if theſe ſcales are rubbed off, the wings are nothing more than a naked membrane. The mouth is furniſhed with a ſpiral tongue, which they can unfold, and roll up again at pleaſure. Their bodies are hairy. This order is divided into three genera.

Genus 43. **PAPILIO,** or butterfly. Antennæ increaſe in thickneſs towards the extremity, and in general terminate in a kind of capitulum or head. Their wings when ſetting or at reſt, are erect, their extremities meeting, or touching one another above the body. They fly in the day time. This genus is divided into ſections, and are thus diſtinguiſhed.

1. Equites, upper wings longer from the hinder corner or angle, to the anterior extremity, than from the ſame point to their baſe, ſome of theſe have filiform antennæ, in which they reſemble the phalæma, but they ſtill differ in the lightneſs and airineſs of their make; they are further divided, and are called,

Troes, theſe are of a dark, or black colour, with bloody ſpots on their breaſt.

Achivi, the colours of theſe are generally gay, without the bloody ſpots of the Troes, but they have an ocellum, or ſpot, reſembling an eye at the inner corner of the poſterior wings, they are

Simple, of one colour, or variegated, adorned with various colours.

2. Heliconii, wings narrow and intire, oftentimes appearing naked or without ſcales; the upper wings oblong and narrow, the under ones in general ſhorter.

3. Danai, wings intire, but divided into two families.

Candidi, the ground colour of the wings always white.

Feſtivi, wings variegated, or adorned with a variety of colours.

4. Nymphales, wings indented, or ſcolloped; there are two families in this diviſion.

Gemmati, wings adorned with eyes, in ſome only the upper ones, in others, the lower, and in many the whole four.

Phalerati, wings beautifully variegated, but without eyes.

5. Plebeii, theſe are in general ſmall, and are either,

Rurales, ſpots and markings of the wings, often very beautiful but opake, not pellucid or tranſparent.

Urbicoli, ſpots on the wings moſtly tranſparent.

To this diviſion of butterflies, into ſections and families, many objections may be made, as is very juſtly obſerved, by that ingenious and able entomologiſt, the late Mr. Thomas Pattiſon Yeates, in his Inſtitutions of Entomology, which is a tranſlation of Linnæus's Ordines et Genera Inſectorum; he there remarks, that the family of the *Plebeii*, in particular, is very inaccurate, and contains inſects very different from one another, at the ſame time that they reſemble, and have all the characters of ſome or other of the preceding ones; under which many of them might be properly arranged; the remaining *Plebeii*, would compoſe a family very diſtinct from all others, and which might be formed into two ſections, the firſt containing ſmall butterflies, having long and flexible, or weak tails, ſlender bodies and clubbed antennæ, as the *Cupido*, the *Marſyas*, the *Bœticus*, &c. the other diſtinguiſhed by the ſhortneſs, thickneſs, or breadth of their head, thorax, and abdomen, and by the ſhape of their upper wings, which in theſe laſt are pointed at the extremity, and long in proportion to their width, as the *Proteus*, *Phidias*, and others.

The Antennæ in this laſt diviſion, are generally uncinnated, or crooked at their extremity; ſome of them have likewiſe tails, but theſe are very broad and ſtrong, and are always ciliated or edged with a fringe of hairs, as in the *Proteus*, &c.

The bloody ſpots are not always found on the breaſts of the Eq. Trojani, nor is the interior angle of the Achivi always adorned with an eye, ſo that the ſureſt method, is to refer ſuch equites as are of dark or mourning colours, to the family of the *Troes*, and thoſe of gay, lively ones, to that of the *Achivi*.

The under wings of a great many of the Papiliones, placed by Linnæus among his *Heliconii*, are ſlightly indented, and as they are without eyes, they ought, ſtrictly ſpeaking, to be referred to the *Nymphales Phalerati*, but are diſtinguiſhable by the delicacy of their texture, and the ſmoothneſs of their wings, which are leſs covered with ſcales, than thoſe of the laſt mentioned family.

The under wings of the *danai feſtivi*, are likewiſe often indented, but in that caſe, they are generally edged with a kind of fringe, or their margins, eſpecially on the under ſide, ſurrounded by one or more *waved* lines, or rows of white ſpots; thoſe butterflies, therefore, whoſe wings are but *ſlightly* indented, adorned with eyes, and the margins ſurrounded by rows of white ſpots, or *narrow waving* lines, belong rather to this family, than to that of the *nymphales gemmati*.

As butterflies from the elegance of their form, and exceſſive beauty of their colours, have more engaged the attention of the curious than any other claſs of inſects, ſo we find more of them in all collections ſent from foreign parts, many people collect them on account of their ſingular beauty, who have not the leaſt taſte for the ſtudy of inſects in general, and therefore we are totally unacquainted with their food, and manner of living; and this we preſume was what occaſioned Linnæus, to deviate from his general rule, in adapting trivial names to them, in which, in general he has been remarkably happy, and ſucceſsful. The trivial names of his Papiliones diſplay, a fund of ingenuity. The firſt diviſion of the Equites, he has named after the Trojan nobles, giving the name of Priam, who was king of Troy, to the moſt ſplendid; the ſecond diviſion are diſtinguiſhed by the names of the Grecian heroes; further diſtinguiſhing all thoſe elegant ones, whoſe hinder wings reſembled tails, by ſome royal name as Paris, in the firſt diviſion, and Agamemnon in the latter. The ſecond ſection or heliconii, take their names from the muſes.

To the third ſection or danai, he has affixed the names of the ſons and daughters of Danaus, which being again divided, he has confined the names of the daughters to the *candidi*, or white ones, and given to the *feſtivi* or party coloured ones, the names of the ſons of Egyptus.

The fourth ſection or nymphales, are named from various nymphs of antiquity; and the fifth ſection or *Plebeii*, from thoſe men among the antients, whoſe names deſerve to be recorded: by this method, he has in ſome meaſure introduced a knowledge of the antients, and rendered the ſtudy of this ſcience more agreeable.

Genus 44. SPHINX, or hawk moth. Antennæ, in ſhape of a priſm, but thicker in the middle than at the extremities. Wings deflected, the outer margins declining towards the ſides, their flight is ſlow and heavy. They are divided into two families.

1. *Legitimæ* { Wings angulated, anus ſimple not terminated with a tuft of hair.
Wings entire, anus ſimple.
2. Wing entire, anus terminated by a tuft of hair.

2. *Adſcitæ*, differ from the others, in their external appearance, and alſo in their caterpillar.

Genus 45. PHALENA. Moth. Antennæ decreaſing from the baſe to the point. Wings generally deflected when at reſt, fly in the evening, or night; they are divided into two families, as under.

1. *Attaci*. Wings incline downward, and are ſpread open, and have either pectinated antennæ, without a tongue.

Pectinated antennæ
Setaceous antennæ } with a ſpiral tongue

2. *Bombyces*. Wings cover the body, nearly horizontal, antennæ pectinatæ; they are alſo

elingues without the ſpiral tongue { wings reverſed
——depreſſed, back ſmooth
——depreſſed, criſtated on the back

Spirilingues with the ſpiral tongue { wings deflected, back ſmooth
ditto, creſted

3. *Noctuæ*. Wings incumbent, antennæ ſetaceous,
elingues without tongues { back ſmooth
Spirilingues having ſpiral tongues { back creſted

4. *Geometræ*. Wings extended horizontally, when the inſect is at reſt.

Theſe are Antennæ feathered { wings angulated, or
Antennæ briſtle ſhaped { round with entire edges

5. *Tortrices*. Wings obtuſe, the exterior margin is curve and declines towards the ſize of the body; they have ſhort palpi.

6. *Pyralis*. The inner margin of the wings in this ſection lay one over the other, the wings themſelves decline a little towards the body; and in ſhape reſemble a delta or triangle, theſe have large palpi, ſome of which curve upwards, others are ſtrait and extended.

7. *Tiniæ*. Wings wrapped or folded round the body ſo as to give the inſect a cylindric form; forehead ſtretched out or advanced forward.

8. *Alucitæ*. Wings ſplit, or divided into branches almoſt to their baſe.

ORDER IV.

INSECTA NEUROPTERA.

The inſects of this order have four membranaceous, naked wings, reticulated with veins, ſo as to appear like network. Their tail is unarmed or without a ſting, but is frequently furniſhed with appendices like pincers, by which the males are diſtinguiſhed. This order contains 7 genera.

Genus 46. LIBELLULA. Mouth armed with jaws, which are always more than two in number, antennæ ſhorter than the thorax, wings expanded without folds, tail furniſhed with a kind of forceps in the male; they are divided into two ſections.

1ſt. Wings extended horizontally when at reſt.

2d. Wings erect, eyes prominent, and placed at a diſtance from each other.

Genus 47. EPHEMERA. Wings erect, hinder ones ſhorter than the others, mouth deſtitute of teeth and palpi, ſtemmata two in number, large, and ſituate above the eyes; tail furniſhed with appendices reſembling hairs or briſtles; theſe are divided into two families.

1ſt. Cauda triſeta; tail with three briſtles.

2. ——— biſeta ——— two briſtles.

Genus 48. PHRYGANIA. Mouth without teeth, but furniſhed with four palpi. The ſtemmata are three in number. Antennæ longer than the thorax, wings incumbent, under ones folded and concealed, under the upper ones; they are divided into two ſections.

1ſt. Abdomen armed with two truncated ſetæ.

2d. Abdomen ſimple without the ſetæ.

Genus 49. HEMEROBIUS. Mouth armed with teeth, palpi 4, no ſtemmata, wings deflected and not folded; antennæ ſetaceous advanced before the head, and longer than the thorax which is of a convex form.

Genus 50. MYRMELION. Mouth armed with jaws, two teeth, and four long palpi, no ſtemmata; the tail in the male is furniſhed with a kind of forceps, formed of two ſtrait filaments, antennæ club ſhaped, length of the thorax; wings deflected.

Genus 51. PANORPA. Roſtrum horny and cylindrical, two palpi, two ſtemmata; antennæ longer than the thorax, tail in the male furniſhed with a chela or weapon, reſembling the claw of a crab.

Genus 52. RAPHIDIA. Head horny, depreſſed or flattened, mouth armed with two teeth and four palpi; ſtemmata three; wings deflected, antennæ as long as the thorax, the anterior part of which is lengthened out and cylindrical, tail of the female terminated by an appendix reſembling a flexible crooked briſtle.

ORDER V.

INSECTA HYMENOPTERA.

The inſects included in this order have four membranaceous wings; the neuters however in ſome genera, and in others the males and females are deſtitute of wings. The tail, except in the male ſex, is armed with a ſting. This order contains ten genera.

Genus 53. CYNIPS. Mouth armed with jaws, but no proboſcis; ſting ſpiral, and moſtly concealed within the body.

Genus 54. TENTHREDO. Mouth armed with jaws, but no proboſcis, wings extended, and tumid as if ſwelled, or of a bulky conſiſtence, ſting dentated like a ſaw, and compoſed of two laminæ, two ſmall tubercules on the ſcutellum at ſome diſtance from each other; they are divided into families from the different formation of their antennæ.

1ſt. Thoſe with clubbed antennæ.
2d. Antennæ of one thread, ſeemingly without articulations.
3d. Antennæ pectinated.
4th. Antennæ articulated, and nearly clavated, but not ſo diſtinguiſhable as in the firſt ſection.
5th. Antennæ threadſhaped, compoſed of 7 or 8 articulations, beſides the baſe.
6th. Antennæ ſetaceous, compoſed of many articulations.

Genus 55. SIREX. Mouth armed with two ſtrong jaws, palpi two, and truncated, antennæ filiform, and contain upwards of 24 articulations, ſting dentated like a ſaw, projected ſtrong and ſtiff, abdomen ſlender, terminating in a point or ſpine from under which the ſting projects. Wings lanceolated and extended their whole length.

Genus 56. ICHNEUMON. Mouth armed with jaws, antennæ of thirty articulations, abdomen generally joined to the body by a pedicle or ſtalk. Sting exerted or projects beyond the abdomen, and is incloſed in a cylindric ſheath of two valves. They are divided into families from the colour of their ſcutellum and antennæ.

1. Scutellum white, antennæ marked with a white ring or circle.
2. Scutellum white, antennæ all black
3. Scutellum } ſame as the thorax { white ring on the antennæ
4. Scutellum } { antennæ all black
5. Antennæ yellow and briſtly
6. Antennæ thread ſhaped, and often but 10 articulations, abdomen oval; the inſects much ſmaller than the others.

Genus 57. SPHEX. Mouth armed with jaws, no tongue, antennæ ten joints; wings extended in each ſex, without folds, and laid horizontally on the back. Sting ſharp and pointed, but concealed within the abdomen. Two ſections.

1. Abdomen joined to the thorax by a petiolum or ſtalk.
2. Abdomen attached without a ſtalk.

Genus 58. CHRYSIS. Mouth armed with jaws, but no proboſcis, antennæ thread ſhaped, firſt articulation longer in proportion to the reſt, which are eleven in number. Abdomen very convex, with a kind of lateral ſcale on the under ſide, anus dentated, and armed with a ſting, which projects a little. Wings extended, body of a ſhining colour as if gilt.

Genus 59. VESPA, waſp. Mouth armed with jaws but no tongue, wings folded longitudinally in both ſexes. Sting ſharp and pointed, but concealed; body without hair; eyes lunular.

Genus 60. APIS, bee. Mouth armed with jaws, proboſcis incloſed in a bivalve ſheath, and inclined downwards under the body. Wings extended and without folds: females and neuters carry a ſharp pointed ſting concealed in their abdomen. This genus is divided into two families.

1. Body ſmooth without any, or very few hairs.
2. Body very hairy.

Genus 61. FORMICA, emmet, ant, or piſmire, is diſtinguiſhed by a little upright ſcale, which is ſituate between the thorax and abdomen. The ſting with which the females and neuters are armed, is concealed within the abdomen: males and females are winged, the neuters apterous.

Genus 62. MUTILLA. No wings in moſt caſes, body covered with a kind of down. Thorax is truncated, or appears to have a part cut off where it joins the abdomen, ſting pointed and concealed within the body.

ORDER VI.

INSECTA DIPTERA.

The inſects of this order have only two wings, but are furniſhed with a poiſer or ballancer, *halteres*, ſituate under each wing, which is terminated by a capitulum or knob. The baſe in moſt caſes is concealed, or ſecured under a little ſcale, by which it is covered, as by a ſhed: this order contains ten genera.

Genus 63. OESTRUS. Deſtitute of a mouth in the place of which three ſmall impreſſed points are found, without any viſible proboſcis or roſtrum.

Genus 64. TIPULA. Head long, upper jaw formed like an arch, palpi two, curve; and are longer than the head, proboſcis ſhort, and bent inwards; they are divided into two ſections.

1. Wings extended when at reſt.
2. Wings cloſed and covering the body.

Genus 65. MUSCA. Mouth formed by a ſoft fleſhy proboſcis, with two lateral lips, but no palpi. They are divided into families from the form of their antennæ.

1. Antennæ ſimple, without a lateral hair or feather.
2. ——— furniſhed with a lateral hair or feather, and theſe again are either

Tomentoſæ, downy or velvety { Plumatæ, with a lateral feather
Piloſæ, with ſtiff hairs. { Setariæ with a lateral hair.

Genus 66. TABANUS. Mouth extended into a fleſhy proboſcis terminated by two lips; roſtrum furniſhed with two pointed palpi, placed on each ſide of, and parallel to the proboſcis.

Genus 67. CULEX. Mouth formed by a flexible ſheath, encloſing ſetæ, or briſtles pointed like ſtings.

Genus 68. EMPIS. Roſtrum horney, inflexed, bivalve, longer than the thorax, the valves horizontal.

Genus 69. CONOPS. Roſtrum projected, and jointed like an elbow or knee.

Genus 70. ASILUS. Roſtrum horny, projected, bivalve, and extended its whole length.

Genus 71. BOMBYLIUS. Roſtrum porrected, ſetaceous very long, and formed of two horizontal valves, in which are contained ſetaceous ſtings or briſtles.

Genus 72. HIPPOBOSCA. Roſtrum, bivalve, cylindrical, obtuſe, and wavering, or ſhaking, as if ill fitted to the mouth.

ORDER VII.

INSECTA APTERA.

This order contains all ſuch inſects as want wings in either ſex; for the whole ſpecies, or every ſex of the ſame inſect, muſt want wings, in order to render it apterous according to Linnæus, and to place it in this order, which contains 14 genera.

Genus 73. LEPISMA. Mouth furniſhed with four palpi, two of which are ſetaceous, and two capitated, feet 6, formed for running, tail terminated by briſtles, body imbricated with ſcales.

Genus 74. PODURA. Antennæ long and ſetaceous. Eyes two in number, 6 feet, and formed for running. Tail forked, bent inwards under the body, elaſtic, and acts like a ſpring, by which the inſect leaps.

Genus 75. TERMES. Antennæ ſetaceous, mouth armed with two jaws; it has two eyes, and ſix feet, made for running.

We have here followed Linnæus's arrangment, and placed the termites among the apterous inſects, which is certainly an error, as they properly belong to the order Neuroptera, it having in its perfect ſtate, four wings without any ſting. It is probable Linnæus never ſaw thoſe inſects, in their perfect or fly ſtate, and he has only deſcribed three ſpecies: we are indebted to that indefatigable naturaliſt, the late Mr. Henry Smeathman, for the particular hiſtory of many of theſe ſpecies.

Genus 76. PEDICULUS, louſe. Mouth armed with an exerted ſting, antennæ as long as the thorax, two eyes, abdomen depreſſed, and as it were formed of lobes; ſix feet.

Genus 77. PULEX, flea. Antennæ filiform, eyes two, roſtrum bent inwards, ſetaceous and conceals a ſting, abdomen compreſſed or flattened; feet ſix, formed for leaping.

Genus 78. ACARUS, mite. Eyes two, remote, one on each ſide the head, eight feet, and two articulated tentacula, in form of feet.

Genus 79. PHALANGIUM. Eyes two on the ſummit of the head, and two others on the ſides, antennæ which are fixed to the fore part of the head, or made like feet, of which there are eight; abdomen round.

Genus 80. ARANEA. Eyes eight, mouth armed with two crotchets, palpi two in number, and headed by the genitaliæ of the males in that ſex, feet eight, anus contains inſtruments for ſpinning, ſhaped like nipples or teats.

Genus 81. SCORPIO, ſcorpion. Eyes eight, three of which are ſeated on each ſide the thorax, and two on the back, palpi two, cheliform; eight feet, and two claws, which are ſituate on the fore part of the head; tail lengthened out, articulated and terminated by a ſharp crooked ſting; on the breaſt and abdomen, are placed two inſtruments called pectines from their form, which reſembles a comb.

Genus 82. CANCER. Eyes two, moveable, generally placed on a foot ſtalk, palpi two, armed with claws, feet eight, beſides two hands terminated with claws, tail articulated and unarmed; they are divided into the following families,

Brachyuri or ſhort tailed crabs {
Thorax ſmooth ſides entire
—— —— jagged or indented
Hairy or ſpinous on the upper part
Armed with ſpines on the upper part, with ſurface uneven.

Macrouri, or long tailed crabs. {
Thorax ſmooth,
—— uneven or tuberculated,
—— armed with ſpines,
hand without fingers, and thorax oblong, ſhell ſhorter than the thorax, ſo as not to cover it entirely.

Genus 83. MONOCULUS. Eyes fixed in the ſhell, very near each other, body covered with a cruſt or ſhell, feet made for ſwimming.

Genus 84. ONISCUS. Antennæ ſetaceous, body oval, fourteen feet.

Genus 85. SCOLOPENDRA, Antennæ ſetaceous, palpi two, jointed or formed of various articulations, body flat, feet equal to the ſegments of the body.

Genus 86. JULUS. Antennæ moniliform, palpi two, jointed, body ſemicylindric, feet twice as many as the ſegments.

Having now gone through the whole of Linnæus's ſyſtem of inſects, we cannot but regret the loſs of that great man, before he was enabled to add the immenſe number of inſects that have been lately diſcovered, and arrange them under their proper orders and genera. It would be a valuable acquiſition to the entomologiſt, and much facilitate the ſtudy, if ſome perſon properly qualified, would undertake to reduce all the inſects, lately deſcribed by other authors, to the Linnæan ſyſtem; for it is but juſtice to that great author to remark, that notwithſtanding the number of inſects now known, are full three times more than when his laſt edition of the Syſtema Naturæ was publiſhed, we have never yet ſeen an inſect, that we could not readily arrange, under one of his orders; and although ſucceeding authors have amazingly increaſed the number of genera, it will be found on examination that they have in general rather ſubdivided the genera of Linnæus, than framed new ones from inſects that would not with propriety have come under one or other of the eighty-ſix genera we have deſcribed. We do not preſume to ſay, that Linnæus's Syſtem; is free from error, as an artificial one, it cannot be perfect, nor can we expect perfection, till we are enabled to form a natural one, and that time we fear is far diſtant. An increaſe of artificial ſyſtems is ſurely a great obſtacle to the improvement of this ſtudy, and the multiplication of genera muſt inevitably impede our progreſs in this branch of knowledge.

It may however gratify many of our readers, to inform them that the different ſyſtems of Geoffroy, Schæffer, and Scopoli, are collated, and the ſynonymous genera, given by Mr. Yeates, in his inſtitutions of entomology. The Syſtem of Baron Charles De Geer is ingenious, but we think by no means equal to that of Linnæus. The writer to whom entomology is moſt indebted, ſince Linnæus, is Mr. Joſ. Chriſt. Fabricius, who has publiſhed a number of ingenious works upon the ſubject, well worthy the attention of all thoſe who wiſh to become proficients in this ſtudy. For this gentleman in his Mantiſſa Inſectorum, in two volumes, publiſhed in 1787, has deſcribed 7184 inſects, and we are in daily expectation of another Mantiſſa, in which many more will be added; we cannot, however, but lament that a perſon ſo eminently qualified to improve this ſcience, ſhould have ſet about framing a new Syſtem, and increaſing the number of genera. The characteriſtic diſtinctions of this author, are taken from the mouths of inſects; many of which are ſo exceedingly minute, and ſuch numbers of them being dry, hard and damaged before we receive them, that we find it totally impoſſible to define them properly. He has divided them into eight claſſes, and 195 genera. There is alſo another work on inſects, publiſhing at this time in Paris, by a laborious and accurate entomologiſt, Mr. Olivier; but this gentleman, we are alſo ſorry to add, has framed a new Syſtem; although in his great outline, he follows Linnæus, adopting his ſeven orders, but dividing the fourth order or hemiptera, into two diviſions, preſerving the name of hemiptera to the firſt; and to the ſecond, he has given the name of orthoptera; his order hemiptera, is again divided into two ſections, the firſt contains the Linnæan, *Fulgora, Cicadæ, Aphis, Thrips, Chermes and Coccus.* The ſecond ſection includes the *Notonecta, Nepa, Cimex*; the order orthoptera, comprehend the *Blatta, Gryllus, Locuſta, and Mantis.* He alſo arranges his orders different from Linnæus, beginning with order

1. Lepidoptera.
2. Neuroptera.
3. Hymenoptera.
4. Hemiptera.
5. Orthoptera.
6. Coleoptera.
7. Diptera.
8. Aptera.

In his genera he includes all the Linnæan ones, but like Fabricius ſubdivides them, introducing many from the latter author, and adopting others from De Geer, and Geoffroy, to which he has added many new ones, extending the number of Genera to 208, when this work, which is illuſtrated with good figures of all the inſects is finiſhed, it will ſhew the neceſſity of adhering to one Syſtem, as the confuſion of names will prevent the entomologiſt, who ſtudies any particular author, from underſtanding thoſe who purſue a different ſyſtem with themſelves; for inſtance, if we ſpeak to a follower of Fabricius about a moth, which after Linnæus, we call a Pyralis, he will immediately, if unacquainted with Linnæus's Syſtem, ſuppoſe us to mean the Pyralis of Fabricius, which is a tortrix of Linnæus, and ſo on with many others: if therefore it is neceſſary to increaſe the diviſions and arrangements, it is certainly neceſſary to avoid uſing the names of one author, and applying them to a different family, as Fabricius and Olivier have done. The Linnæan, Pyralis and Geometra, they have united under the name of Phalæna, to his Tortrix; they have given that of Pyralis; they have alſo divided his Tineæ, and preſerved his name to the greateſt part of them, and to the remainder, they have given that of Alucitæ, which he had applied to another family, named by them Pterophorus.

Linnæus has been very attentive to the trivial names of his four laſt families of moths, giving the ſame termination to each family, or to each diviſion of a family, in the geometræ; they end in ata, or aria, as the antennæ are either pectinated or ſetaceous; the tortrices all end in ana, the pyralides in lis; the tineæ in ella, and the alucitæ in dactyla; ſo that on receiving a moth from a friend with its name, we could tell by the termination only, in what family to look for it, if we were not ſufficiently acquainted with the ſcience, to know it by its outward appearance, and characteriſtic markings. The great number of theſe ſmall moths, and the difficulty there was in diſcovering their habits and œconomy, induced Linnæus to compliment the admirers and reſearchers into this branch of nature, by naming them after ſuch perſons; and in this he appears to have ſhewn no partiality to particular men or countries, but to have ſelected thoſe, who really deſerved ſuch reſpect: in this inſtance, he alſo diſcriminated between thoſe who only collected and preſerved them, and thoſe who enriched the ſcience, by publiſhing their obſervations and diſcoveries; the firſt will be found only among the tortrices, or thoſe ending in ana, as Burmaniana &c. &c. the latter among the tineæ or thoſe terminating in ella, as De Geerella, &c. &c.

The preceding Syſtem of Entomology, was preſented to me by Mr. THOMAS MARSHAM, Secretary to the Linnæan Society. *Thoſe who wiſh to initiate themſelves in this branch of* Natural *Hiſtory, will I am confident find this Syſtem fully anſwer their purpoſe; as it is clear, conciſe, and claſſical. Further to illuſtrate it,* Mr. Marſham *has formed a Plate explanatory of the different Parts of the various Inſects in their reſpective Metamorphoſes. The other Plates of this Claſs of numerous Animals repreſent all the different Genera; and where the Species vary conſiderably, to render the* Syſtem *more complete, ſeveral Species will be given of a Genus, ſimilar to thoſe in* Ornithology. *I hope the Production will conduce to the Entertainment of my Subſcribers, and am happy in an opportunity of thus acknowledging my obligations to the Author for his liberal contribution to the Support of the Work.*

PATER-NOSTER-ROW. C. COOKE.

BRITISH 18 MR 63 MUSEUM

ENTOYER, or **Entoire**, in heraldry, is uſed to expreſs a bordure, charged entirely with things without life.

ENTRAILS, the inteſtines or guts of an animal. See Intestines.

Entrails is alſo uſed, in a more extenſive ſenſe, for the viſcera, or all the parts contained in the cavities of the bodies of animals.

ENTRANCE *of Hounds*, a phraſe uſed by our ſportſmen, to expreſs the inſtruction of theſe creatures in the art of hunting. They are ſaid to be entered when they are thoroughly taught this.

Method of entering Hounds.

The time of entering of hounds, is, when they are ſeventeen or eighteen months old; they are then to be taught to take the water and ſwim; they are to be laid abroad in the heat of the day, to enure them to fatigue and exerciſe; and they muſt be frequently led through flocks of ſheep, and warrens, to uſe them to be under command, and to know that they are to run at nothing but what the huntſman orders. They muſt be carefully inſtructed each to know his own name, and to underſtand the voice of the huntſman, and the notes of the horn uſed in hunting; and finally, to uſe their own language in a proper manner.

The beſt time of entering them is about noon; and it ſhould be in a fair warm day; for if they be entered in the morning, they will give out when the heat of the middle of the day comes on. Take the moſt advanced, that the game may not ſtand long before them, and let them be well rewarded when all his over. This ought to be repeated at leaſt once a week, for two months ſucceſſively; by this means they will be ſo fleſhed and ſeaſoned with what game you may enter them at, that they will never afterwards leave off the purſuit. The new hounds ſhould always be entered with the beſt and ſtauncheſt hounds that can be had; and there is not to be one barking dog ſuffered in the field on this occaſion.

Whatever chaſe the hounds are intended for, the hare is the beſt game to enter them at, becauſe in this chace, they will learn all the turns and doubles that they can poſſibly meet within any other kind, and how to come to the hollo. They will learn alſo from this chace, to have a perfect and nice ſcent, and hard feet, by being uſed to highways, beaten paths, and dry hills. The hounds, when firſt entered, muſt have all the advantages given them that can be. When the hare is put up, from her form, it muſt be obſerved which way ſhe went, and the ſcent muſt be left to cool a while, and then they muſt be laid in, and helped as much as can be, by wind, view, hollo, or pricking the paſſage; nor will it be amiſs, for the firſt time to give them a hare tired the ſame morning in her courſe.

Some are of opinion, that the beſt way to enter young hounds, is, to take a live hair, and trail her upon the ground, ſometimes one way, and ſometimes another, and then to draw her off to a convenient diſtance, and hide her, that the dogs, taking ſcent, may follow all the traces through which ſhe was drawn, and at length find her. The huntſman ought very well to underſtand the nature and diſpoſition of his hounds, in finding out the game; for ſome hounds are of that temper, that when they have found the ſcent, they will run forward with it, not making any noiſe, nor ſhew of the tail; others, when they have found a head, will ſhew the game; and ſome, having found the footings of the beaſt, will prick up their ears a little, and either bark, or only wag their ears, or the hinder part of their bodies. This difference of natural diſpoſition, the huntſman is particularly to obſerve in the young and newly entered pack, otherwiſe he will never underſtand them, nor ever be able to hunt them to any credit or advantage.

For entering the hound at hart or buck, he ſhould be in prime caſe, for then he cannot ſtand up, or hold the chaſe ſo long. The foreſt pitched upon ſhould have all the relays at equal diſtances, as nearly as may be; but then the young hounds ſhould always have ſome old ſtaunch ones to enter them, and they ſhould be led to the fartheſt and laſt relay, and the hart or buck ſhould be hunted to them. Being come up, the old hounds ſhould be uncoupled; and when they have found the hart, and well entered the cry, then the young ones are to be uncoupled alſo; and if any of them are found to lag behind, they muſt be whipped and beaten forward.

In whatever place the hart is killed, the neck ſhould be immediately flayed, and the hounds rewarded; for it is beſt always to do this while the fleſh is hot. Another very good method of entering hounds at the buck, is to take one in the toils or nets, and to wound one of his legs, ſo as to diſable him from running either very ſwiftly or very far; then let him looſe, and firſt let a bloodhound trace the creature, then let looſe all the young hounds; and when they have run down the animal, reward them with the neck. Some enter their hounds with a toil; but this is a bad way; for the hart being in this caſe always in ſight, and not able to run an end, makes a great number of doubles and turnings: this is very different from the chaces they are to meet with afterwards; and when they find a hart run in the common way, ſtraight forward, and out of ſight, they will leave the chace, as unlike that by which they were taught.

ENTRY, or **Entrance**, in its general ſenſe, denotes a door, gate, paſſage, &c. through which to enter, or arrive within a place.

Entry, in book-keeping. See Book-keeping, Sect. IV.

Entry is ſometimes alſo uſed to denote a duty or impoſt laid on commodities imported into a ſtate, either by land or ſea. The duties of entry, or importation, are paid according to a tariff ſettled for that purpoſe. Where the duty of entry of any commodity is not fixed by the tariff, it is paid by eſtimation, i. e. in proportion to what ſome other commodity of nearly the ſame quality and value uſes to pay. In making entries inwards, it is uſual for merchants to include all the goods they have on board the ſame ſhip in one bill, though ſometimes there may happen to be upwards of twenty ſeveral kinds; and in caſe the goods are ſhort entered, additional or port entries are now allowed; though formerly the goods ſo entered were forfeited. As to bills of entry outwards, of including goods to be exported, upon delivering them and paying the cuſtoms, you will receive a cocket, which teſtifies your payment thereof, and of all duties for ſuch goods. If ſeveral ſorts of goods are exported at once, of which ſome are free, and others pay cuſtoms, the exporter muſt have two cockets, and therefore muſt make two entries. Entries of goods, on which a draw-back is allowed, muſt likewiſe contain the name of the ſhip in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken, that the cuſtoms for theſe goods were paid as the law directs; you muſt carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which muſt be given to the ſurveyor, ſearcher, or land-waiter, that they may certify the quantity of goods; after which the certificate muſt be brought back to the collector and comptroller, or their deputies, and oath made, that the ſaid goods are really ſhipped, and not landed again in any part of Great Britain.

Entry alſo denotes a ſolemn reception, or a ceremony performed by kings, princes, ambaſſadors, legates, &c. upon their firſt entering a city, or their return in triumph from ſome expedition.

Entry, in law, ſignifies the taking poſſeſſion of lands or tenements, in virtue of a title thereto.

Entry is alſo uſed for a writ which grants poſſeſſion of lands or tenements to a perſon, on account of a legal right thereto.

ENTYPOSIS, from εντυποω, *I make an impreſſion*, in anatomy, the articulation of the ſhoulder with the arm.

ENVELOPE, in fortification, denotes a mount of earth ſometimes raiſed in the ditch of a place, and ſometimes beyond it, being either in form of a ſimple parapet, or of a ſmall rampart bordered with a parapet.

ENVELOPED, in heraldry, is where a ſnake entangles himſelf round a beaſt or any other thing.

ENUMERATION, the act of enumerating, or counting. At the time of our Saviour's birth, Auguſtus Cæſar had commanded an enumeration to be made of all the world, or rather of all the people under his empire. Though ſeveral able authors are of opinion, that the cenſus tax, or enumeration mentioned by St. Luke, did not extend to the whole empire, but only to the people of Judæa.

Enumeration, in rhetoric, denotes a part of the peroration, wherein the orator, collecting the ſcattered heads of what has been delivered throughout the whole, makes a brief and artful rehearſal or recapitulation thereof.

ENUNCIATION, a ſimple expreſſion or declaration of a thing, in terms either of affirmation or denial.

ENVOY, a perſon deputed, or ſent purpoſely to negociate ſome particular affair with a foreign prince or republic. Thoſe ſent from the courts of England, and France, &c. to Genoa, the princes of Germany, and other petty princes and ſtates, do not go in quality of ambaſſadors, but of envoys. Add, that thoſe ſent from one great prince or ſtate to another, as from the king of England to the emperor, &c. when the affair they go upon is not very ſolemn and important, have frequently no other character but that of envoys. Envoys are either ordinary or extraordinary. Both kinds are under the protection of the law of nations, and enjoy all the privileges of ambaſſadors, only differing from them in this, that the ſame ceremonies are not performed to them.

ENVY, in ethics, is defined by Mr. Locke, to be an uneaſineſs of mind, occaſioned by the conſideration of a good we diſcover in poſſeſſion of another perſon, whom we deem leſs worthy of it than ourſelves. It is a compoſition of ſorrow and hatred, and ſtands in direct oppoſition to congratulation. Envy, in its nature and effects, is the baſeſt, moſt miſchievous, and moſt tormenting of all paſſions.

Envy, in mythology, is repreſented by the Greek and Roman poets as an infernal divinity, with ſquinting eyes, lean body, pale countenance, diſturbed air, head encompaſſed with ſerpents, &c.

EPACTS, in chronology, the exceſſes of the ſolar month above the lunar ſynodical month; and of the ſolar year above the lunar year of twelve ſynodical months; or of ſeveral ſolar months above as many ſynodical months; and ſeveral ſolar years above as many dozen of ſynodical months. The epacts then, are either annual or menſtrual. Epacts, menſtrual, are the exceſſes of the civil or calendar month above the lunar month. Epacts, annual, are the exceſſes of the ſolar year above the lunar.

EPANALEPSIS, Επαναληψις, called alſo *epanadiploſis*, in rhetoric, the repetition of the ſame word in the beginning of one ſentence, and at the end of another, Thus Virgil,

Ambo florentes ætatibus, Arcades ambo.

EPANODUS, Εϖανοδος, in rhetoric, a repetition of the ſame words in an inverted order; thus,

Nox brevis nimis, ah! nimis brevis nox. Voſſ. Rhet. lib. v. p. 298.

EPAULE, or Espaule, in fortification, the ſhoulder of the baſtion, or the angle made by the face and flank, otherwiſe called the *angle of the epaule.* The word is pure French, and literally ſignifies *ſhoulder.*

EPAULEMENT, in fortification, a ſide-work haſtily thrown up, to cover the cannon or the men. It is made either of earth thrown up, of bags filled with ſand or earth, or of gabions, faſcines, &c. with earth: of which latter ſort the epaulements of the places of arms for the cavalry behind the trenches uſually are.

EPAULETTES, are a kind of ſhoulder-knots choſen for the ſoldiers, which are to be of the colour of the facing, with a narrow yellow or white tape round it, and worſted fringe; thoſe for the officers are made of gold or ſilver lace, with a rich fringe; they are badges of diſtinction worn on one or both ſhoulders. Thoſe of the dragoon-guards, horſe, and dragoons, are worn on the left ſhoulder: the light-dragoons, and officers of grenadiers, have one on each ſhoulder: thoſe of the battalion wear one on the right ſhoulder only, which is to be made of embroidery or lace, with a gold or ſiver fringe. Thoſe of the royal regiment of artillery are to be gold embroidery with gold fringe on ſcarlet cloth, and worn on the right ſhoulder.

EPHEMERA, in medicine, an epithet applied to ſome thing that only laſts a day; particularly to a ſort of fever, which terminates in the compaſs of twenty four hours, called by Galen εΦημερος ϖυρετος, *febris ephemera*, by the Latins, *diaria.* The word, and the following one, *ephemerides*, are formed of the prepoſition επι, *de, of*, and ημερα, *dies, day.*

Ephemera, in the Linnæan ſyſtem of entomology, a diſtinct genus of the neuroptera order. For the deſcription and claſſification, ſee Syſtem of Entomology.

EPHEMERIDES, in aſtronomy, tables calculated by aſtronomers, ſhewing the preſent ſtate of the heavens for every day at noon, that is the places wherein all the planets are found at that time. In England, the nautical almanac, or aſtronomical ephemeris, publiſhed annually by anticipation, under the direction of the commiſſioners of longitude, is the moſt conſiderable.

EPHOD, אפר, derived from אפר, *aphad, to clothe*, a ſacerdotal garment, in uſe among the antient Jews, ſuppoſed to have been a kind of linen alb, or ſurplice, wore by perſons of diſtinction, of various characters. There were two kinds of ephods; the one, common to all who aſſiſted in the temple, being only made of common linen, mentioned in the firſt book of Samuel, ii. 18; the other, peculiar to the high prieſt, mentioned Exod. xxviii. 6. 15. to be made of gold, of blue, and of purple, of ſcarlet, and fine twiſted linen, with cunning work; having two ſhoulder-pieces, with a curious girdle of the ſame matter, whereon were two onyxes, with the names of the children of Iſrael engraved thereon. It is alſo expreſſed in the ſecond book of Samuel, vi. 14. that upon the removal of the ark of the covenant from the houſe of Obed-Edom, David danced for joy, girt with a linen ephod; whence ſome authors have concluded, that the ephod was alſo a regal garment, worn on ſolemn occaſions.

EPHORI, in Grecian antiquity, magiſtrates eſtabliſhed in ancient Sparta to balance the regal power. The authority of the ephori was very great. They ſometimes expelled and even put to death the kings, and aboliſhed or ſuſpended the power of the other magiſtrates, calling them to account at pleaſure. There were five of them, others ſay nine. They preſided in the public ſhews and feſtivals. They were entruſted with the public treaſure; made war and peace; and were ſo abſolute, that Ariſtotle makes their government equal to the prerogative of a monarchy. They were eſtabliſhed by Lycurgus.

EPIC, or Heroic, poem, a poem expreſſed in narration, formed upon a ſtory partly real, and partly feigned; repreſenting, in a ſublime ſtyle, ſome ſignal and fortunate action, diſtinguiſhed by a variety of great events, to form the morals, and affect the mind with the love of heroic virtue.

We may diſtinguiſh three parts of the definition, namely, the matter, the form, and the end. The matter includes the action of the fable, under which are ranged the incidents, epiſodes, characters, morals, and machinery. The form comprehends the way or manner of the narration, whether by the poet himſelf, or by any perſons introduced, whoſe diſcourſes are related: to this branch likewiſe belong the moving of the paſſions, the deſcriptions, diſcourſes, ſentiments, thoughts, ſtyle, and verſification; and beſides theſe, the ſimilies, tropes, figures, and, in ſhort, all the ornaments and decorations of the poem. The end is to improve our morals, and increaſe our virtue.

EPICŒNE, Εϖικοινον, in grammar, a term applied to nouns, which, under the ſame gender and termination, mark, indifferently, two kinds of ſexes. Such, in Latin, is, *aquila*, *veſpertilio*, &c. which ſignify equally a male or female eagle or bat. Grammarians diſtinguiſh between epicœne and common. A noun is ſaid to be common of two kinds, when it may be joined either with a maſculine or a feminine article; and epicœne, when it is always joined to ſome one of the two articles, and yet ſignifies both genders.

EPICUREAN *Philoſophy*, the doctrine or ſyſtem of philoſophy maintained by Epicurus and his followers. His philoſophy conſiſted of three parts; canonical, phyſical, and ethereal. The firſt was about the canons or rules of judging. The cenſure which Tully paſſes upon him for his deſpiſing logic, will hold true only with regard to the logic of the Stoics, which he could not approve of, as being too full of nicety and quirk. Epicurus was not acquainted with the analytical method of diviſion and argumentation, nor was he ſo curious in modes and formation as the Stoics. Soundneſs and ſimplicity of ſenſe, aſſiſted with ſome natural reflections, was all his art. His ſearch after truth proceeded only by the ſenſes; to the evidence of which he gave ſo great a certainty, that he conſidered them as an infallible rule of truth, and termed them the *firſt natural light of mankind.*

In the ſecond part of this philoſophy he laid down atoms, ſpace, and gravity, as the firſt principles of all things; he did not deny the exiſtence of God, but thought it beneath his majeſty to concern himſelf with human affairs; he held him a bleſſed immortal being, having no affairs of his own to take care of, and above meddling with thoſe of others. As to his ethics, he made the ſupreme good of man to conſiſt in pleaſure, and conſequently ſupreme evil in pain. Nature itſelf, ſays he, teaches us this truth; and prompts us from our birth to procure whatever gives us pleaſure, and avoid what gives us pain. To this end he propoſes a remedy againſt the ſharpneſs of pain: this was to divert the mind from it, by turning our whole attention upon the pleaſures we have formerly enjoyed. He held that the wiſe man muſt be happy, as long as he is wiſe: the pain, not depriving him of his wiſdom, cannot deprive him of his happineſs. There is nothing that has a fairer ſhew of honeſty than the moral doctrine of Epicurus. Gaſſendus pretends, that the pleaſure in which this philoſopher has fixed the ſovereign good, was nothing elſe but the higheſt tranquillity of mind in conjunction with the moſt perfect health of body: but Tully, Horace, and Plutarch, as well as almoſt all the fathers of the church, give us a very different repreſentation: indeed the nature of this pleaſure, in which the chief happineſs is ſuppoſed to be ſeated, is a grand problem in the morals of Epicurus. Hence there were two kinds of Epicureans, the rigid and the remiſs; the firſt were thoſe who underſtood Epicurus's notion of pleaſure in the beſt ſenſe, and placed all their happineſs in the pure pleaſures of the mind, reſulting from the practice of virtue: the looſe or remiſs Epicureans, taking the words of that philoſopher in a groſs ſenſe, placed all their happineſs in bodily pleaſures or debauchery.

EPICYCLE, in aſtronomy, a circle, whoſe centre is on the circumference of another circle which bears it, and which for that reaſon is called its deferent. The word is formed of the Greek επι, *upon*, and κυκλος, *circle*, q. d. *a circle on a circle.*

EPICYCLOID, in geometry, denotes a curve generated by the revolution of a point of the periphery of a circle, along the convex or concave part of another circle.

EPIDEMIC, Εϖιδημιος, denotes a general or ſpreading diſorder, as a plague, ariſing from ſome corruption or malignity in the air, which ſeizes great numbers of people in a little time. The word is Greek, formed of εϖι, and δημος, *populus, people*; ſuch diſeaſes running among all kinds of people, of whatever age, ſex, quality, &c. as ariſing from a common or general cauſe. The Latins call them *populares morbi, popular diſeaſes*; in oppoſition to thoſe called *ſporadici*, which are only here and there, as riſing from private or particular cauſes. Epidemic diſeaſes differ from endemial: which imports diſeaſes peculiar to ſome particular country, region, or people; whereas epidemic diſeaſes are ſuch as are peculiar to certain ſeaſons.

EPIDERMIS, in anatomy, the cuticle, or ſcarf-ſkin. The word is formed of the Greek εϖι, *on, over*, and δερμα, *ſkin.*

EPIDIDYMIS, in anatomy, a little round body, on the back of each teſticle; called alſo Paraſtata. See Syſtem of Anatomy, Part III. Sect. II.

EPIGASTRIC *Region*, in anatomy, is a name given to the upper part of the abdomen; reaching from the cartilago xiphoides, almoſt to the navel. See Syſtem of Anatomy, Part V. Sect. I. It is uſually divided into three parts: the ſides, or lateral parts, called hypochondria; and the middle, the epigaſtrium.

EPIGLOTTIS, of εϖι, *upon*, and γλωσσα, or γλωττα, *tongue*, in anatomy, the cover, or lid, of the larynx. The epiglottis is a thin, moveable cartilage, made in form of a leaf of ivy, or a little tongue, and therefore likewiſe called lingula; ſerving to cover the cleft, or rima, of the larynx, called glottis. See Syſtem of Anatomy, Part V. Sect. XVIII.

EPIGRAM, in poetry, a ſhort poem, or compoſition in verſe, treating only of one thing, and ending with ſome point, or lively ingenious thought. The word is formed of επιγραμμα, *inſcription*, of εϖιγραΦειν, *to inſcribe, or write upon.* Epigrams then, originally ſignify inſcriptions, and they derive their origin from thoſe inſcriptions placed by the ancients on their tombs, ſtatues, temples, triumphal arches, &c.

One great beauty of the epigram is, to leave ſomething for the reader to gueſs, or ſupply. Nothing pleaſes the mind ſo much, as to find ſomething in itſelf in the objects preſented it; nor does any thing diſguſt it more than to preclude it from ſhewing and exerciſing a faculty it values itſelf for. The epigram admits of great variety of ſubjects: ſome are made to praiſe, and others to ſatirize, which laſt are much the eaſieſt; ill nature ſerving inſtead of point and wit. The epigram being only a ſingle thought, it would be ridiculous to expreſs it in a great number of verſes; it muſt have its unity like the drama. The comedy has an action for its ſubject, and the epigram a thought.

EPILEPSY, formed of επιλαμβανω, *I ſurpriſe*, or *ſeiſe hold of one*, in medicine, a convulſion, either of the whole body, or ſome of its parts; attended with a deprivation of the ſenſes and underſtanding; and returning from time to time in fits, or paroxyſms. In Engliſh it is uſually called the *falling ſickneſs*, becauſe people fall down when attacked by it. See Syſtem of Medicine.

EPILOGUE, in oratory, the end or concluſion of a diſcourſe, ordinarily containing a recapitulation of the principal matters delivered.

Epilogue, in dramatic poetry, a ſpeech addreſſed to the audience, after the play is over, by one of the principal actors therein; uſually containing ſome reflections on certain incidents in the play, eſpecially thoſe in the part of the perſon that ſpeaks it; and having ſomewhat of pleaſantry, intended to compoſe the paſſions raiſed in the courſe of the repreſention: a practice which is ridiculed by the Spectator; and compared to a merry jigg upon the organ after a good ſermon, to wipe away any impreſſions that might have been made thereby, and ſend the people away juſt as they came.

EPIPHANY, a Chriſtian feſtival, otherwiſe called the *manifeſtation of Chriſt to the Gentiles*, obſerved on the ſixth of January, in honour of the appearance of our Saviour to the three magi, or wiſe men, who came to adore him and bring him preſents. The feaſt of epiphany was not originally a diſtinct feſtival; but made a part of that of the nativity of Chriſt, which being celebrated 12 days, the firſt and laſt of which were high or chief days of ſolemnity, either of theſe might properly be called epiphany, as that word ſignifies the appearance of Chriſt in the world. The word in the original Greek, επιφανια, ſignifies *appearance* or *apparition*; and was applied, as ſome critics will have it, to this feaſt, on account of the ſtar which appeared to the magi. St. Jerom and St. Chryſoſtom take the epiphany for the day of our Saviour's baptiſm, when he was declared to men by the voice, *Hic eſt filius meus dilectus, in quo mihi complacui:* "This is my beloved ſon, in whom I am well pleaſed." And accordingly it is ſtill obſerved by the Cophtæ and Ethiopians in that view. Others contend, that the feaſt of Chriſtmas, or the nativity of our Saviour, was held in divers churches on this day; which had the denomination *epiphany*, or *appearance*, by reaſon of our Saviour's firſt appearance on earth at that time. And it muſt be allowed, that the word is uſed among the ancient Greek fathers, not for the appearance of the ſtar to the magi, but for that of our Saviour to the world: in which ſenſe, St. Paul uſes the word *epiphania*, in his ſecond epiſtle to Timothy, c. i. v. 10.

EPIPHONEMA, Επιφωνημα, *acclamation*, in rhetoric, a ſententious ſort of exclamation, which is frequently added after a narrative, or rehearſal of any thing remarkable; containing uſually a lively, cloſe reflection on the ſubject there ſpoken of, and intended to give it greater force, and render it more affecting to the hearers. Such is that of St. Paul, when after diſcourſing of the rejection of the Jews, and the vocation of the Gentiles, he cries out,

> *O the depth of the wiſdom and knowledge of God!*

Such alſo is that of Lucretius, after relating the ſtory of Agamemnon's ſacrificing his daughter Iphigenia:

> *Tantum religio potuit ſuadere malorum!*

The epiphonema is uſually expreſſive of the milder and more gentle paſſions, and is not ſo vehement and impetuous as exclamation.

EPIPHYSIS, Επιφυσις, in anatomy, a leſſer bone, or bony ſubſtance, adhering, or growing to another, by the intervention of a cartilage. See Syſtem of Anatomy, Part I. Sect. II.

EPILOON, in anatomy, a fattiſh membrane, ſpread over the inteſtines, and entering even into the ſeveral ſinuoſities thereof: called alſo the omentum, and popularly the caul. The word is formed of the Greek Επιπλεειν, *to ſwim upon*, becauſe it ſeems to float on the inteſtines.

EPISCOPACY, the quality of epiſcopal government, or that form of church diſcipline, wherein dioceſan biſhops are eſtabliſhed, diſtinct from, and ſuperior to, prieſts or preſbyters. See Bishop. Epiſcopacy, and preſbytery, have been alternately eſtabliſhed and aboliſhed in Scotland.

EPISCOPAL, ſomething that belongs to a biſhop. The word is formed of the Greek επισκοπος, *overſeer*, derived from επισκοπεω, *inſpicio*, *I inſpect*, or *overlook*. Epiſcopal government, is the government of a dioceſe, wherein one ſingle perſon, legally conſecrated, preſides over the clergy of a whole diſtrict, in quality of head, or ſuperintendent thereof; conferring order, and exerciſing a ſort of juriſdiction. The preſbyterians reject the epiſcopal eſtabliſhment, and condemn the epiſcopal orders as a human inſtitution, the mere reſult of pride and ambition. Among the epiſcopal functions, the principal part is that of holding frequent viſitations of the dioceſe.

EPISCOPALIANS, in church hiſtory, an appellation given to thoſe who prefer the epiſcopal government and diſcipline to all others. By the teſt act, none but Epiſcopalians, or members of the church of England, are qualified for any office, civil or military.

EPISODE, Επεισοδιον, from επι, *upon*, and εισοδος *entry*, is commonly conceived to be a ſeparate incident, ſtory, or action, which an hiſtorian, or poet, inſerts, and connects with his principal action; to furniſh out the work with a greater diverſity of events; though, in ſtrictneſs, all the particular incidents, whereof the action or narration is compoſed, are called epiſodes. Epiſode, in dramatic poetry, was the ſecond part of the ancient tragedy. The origin and uſe of epiſodes is deſcribed by M. Hedelin, and F. Boſſu. Tragedy, in its original, being only a hymn ſung in honour of Bacchus, by ſeveral perſons, who made a kind of chorus, or concert of muſic, with dancing, and the like; to diverſify the repreſentation a little, and divert the audience, they determined at length to divide the ſinging of the chorus into ſeveral parts, and to have ſomething rehearſed in the intervals. At firſt, a ſingle perſon, or actor, was introduced, then two, then more; and what the actors thus rehearſed, or entertained the audience with, being ſomething foreign, or additional to, or beſide, the ſong of the chorus, and no neceſſary part thereof, was called επεισοδιον, *epiſode*. And hence tragedy came to conſiſt of four parts, the *prologue*, *epiſode*, *exode*, and *chorus*. The prologue was all that preceded the firſt entrance of the chorus. The *epiſode*, all that was interpoſed between the ſingings of the chorus. The *exode*, all that was rehearſed after the chorus had done ſinging. And the *chorus*, was the grex, or company, that ſung the hymn.

Episode, in epic poetry. The term epiſode, by being tranſplanted from the ſtage, did not change its nature. All the difference between the tragic and epic epiſodes, is, that the latter are more ample than the former. The ſubject of a poem may be lengthened two ways; either by the poet's making uſe of a great many of his epiſodes; or by his amplifying, and giving a greater extent to every one. By this latter method, chiefly, it is, that the epic poets lengthen their poems much beyond the dramatic.

EPISPASTIC, in medicine, a topical remedy, which being applied to the external parts of the body, attracts the humours to that part.

EPISTLE, denotes the ſame with a miſſive letter; but is now chiefly uſed in ſpeaking of ancient writings, as the epiſtle of St. Paul, epiſtles of Cicero, epiſtles of Pliny, &c.

Epistles *and Goſpels*, in the liturgy of the church of England, are ſelect portions of ſcripture, taken out of the writings of the evangeliſts and apoſtles, and appointed to be read, in the communion-ſervice, on Sundays and holidays. They are thought to have been ſelected by St. Jerom, and by him put into the lectionary. It is certain, they were anciently appropriated to the days whereon we now read them, ſince they are not only of general uſe throughout the weſtern church, but are alſo commented upon in the homilies of ſeveral ancient fathers, which are ſaid to have been preached upon thoſe very days to which theſe portions of ſcripture are now affixed.

The epiſtles and goſpels are placed in an admirable order and method, and bear a ſpecial relation to the ſeveral days whereon they are read. The year is diſtinguiſhed into two parts; the firſt being deſigned to commemorate Chriſt's living among us, the other to inſtruct us to live after his example. The former takes in the whole time from Advent to Trinity-Sunday; the latter, all the Sundays from Trinity to Advent During the firſt of theſe ſeaſons, the epiſtles and goſpels are calculated to raiſe in us a grateful ſenſe of what our Saviour did and ſuffered for us, and ſet before our eyes his nativity, circumciſion, and manifeſtation to the Gentiles; his doctrines, and miracles; his baptiſm, faſting, and temptation; his agony and bloody ſweat; his croſs and paſſion; his death, burial, reſurrection, and aſcenſion; and his miſſion of the Holy Ghoſt. During the ſecond ſeaſon of the year, the epiſtles and goſpels tend to inſtruct us in the true paths of Chriſtianity.

EPISTOLARY, a term uſed in the phraſe epiſtolary ſtile. As the matter of an epiſtle is the ſame with that of converſation, it ſhould not differ in the manner of expreſſion; and therefore, all pomp and ſtudy of language are not only needleſs but very improper: the moſt plain and eaſy way of conveying our thoughts muſt certainly be beſt, as being moſt natural. Purity in the choice of words, and juſtneſs of conſtruction, joined with perſpicuity, are the chief properties of this ſtyle: to which purpoſe Cicero obſerves, that in writing letters we make uſe of common words and expreſſions. And Seneca ſays, I would have my letters be like my diſcourſes, when we either ſit or walk together, unſtudied and eaſy. Ep. 75. ad Lucill. However, as the ſubjects of epiſtles are various, they will neceſſarily acquire ſome variety in the manner of expreſſion. If the ſubject be weighty and momentous, the language ſhould be ſtrong and ſolemn; in things of a lower nature, more free and eaſy; and upon lighter matters, jocoſe and pleaſant. In exhortations, it ought to be lively and vigorous; in conſolations, kind and compaſſionate; and in adviſing, grave and ſerious. In narratives, it ſhould be clear and diſtinct, in requeſts, modeſt; in commendations, friendly, without adulation; in proſperity, chearful; and mournful, in adverſity. In a word the ſtyle ought to be accommodated to the particular nature of the ſubject about which it is converſant. Beſides, the different character of the perſon, to whom the letter is written, requires a little difference in the modes of expreſſion. Superiors ſhould be addreſſed with reſpect; inferiors, with courteſy; and equals, with civility. Old men and young, the grave and facetious, courtiers and philoſophers, friends and ſtrangers, require ſome variety in the mode of addreſs. The epiſtles of Cicero, the ſtyle of which is plain and ſimple, and yet pleaſant and engaging, furniſh a proper model in this reſpect.

EPITAPH, Εϖιταφιον, from *εϖι*, *upon*, and *ταφος*, *ſepulchre*, a monumental inſcription, in honor or memory of a perſon defunct; or an inſcription engraven or cut on a tomb, to mark the time of a perſon's deceaſe, his name, family, and uſually ſome eulogy of his virtues or good qualities.

In epitaphs, the dead perſon is ſometimes introduced by way of proſopopœia, ſpeaking to the living; of which we have a fine inſtance, worthy the Auguſtan age, wherein the dead wife thus beſpeaks her ſurviving huſband.

Immatura peri: ſed tu, felicior, annos
Vive tuos, conjux optime, vive meos

The French have a proverb, *Menteur comme une epitaphe*; *He lies like an epitaph*; an alluſion to the eulogies ordinarily contained therein, which are not always over juſt.

In the anthologies, or collections of epigrams, we have abundance of ſuch epitaphs, ſome of them ludicrous and ſatirical, others grave. For a ſpecimen, we ſhall here add a very beantiful one, compoſed by Mr. Cowley, on himſelf, to be put in a little country houſe, whither he retreated from the court and town to ſpend his laſt days.

Hic, O viator, ſub lare parvulo,
Couleius *hic eſt conditus, hic jacet*
Defunctus humani laboris
Sorte, ſupervacuaque vita;
Non indecora pauperie *nitens*,
Et non inerti nobilis otio,
Vanoque dilectis popello,
Divitiis, animoſus *hoſtis*.
Poſſis ut illum dicere mortuum,
En terra jam nunc quantula *ſufficit?*
Exempta ſit curis, viator,
Terra ſit illa levis, precare.
Hic ſparge flores, *ſparge breves* roſas;
Nam vita gaudet mortua floribus;
Herbiſque odoratis corona
Vatis adhuc cinerem calentem.

EPITALAMIUM, Εϖιθαλαμιον, formed of εϖι and θαλαμος, *bride chamber*, in poetry, a nuptial ſong, or a compoſition, uſually in verſe; on occaſion of a marriage between two perſons of eminence. The topics it chiefly inſiſts on are the praiſes of matrimony, and of the married couple, with the pomp and order of the marriage ſolemnity; it concludes with prayers for their proſperty, their happy offſpring, &c. This kind of poetry is very ancient.

EPITHET, Εϖιθετον, a noun adjective expreſſing ſome quality of a ſubſtantive, to which it is joined. The word is formed of *εϖι*, *upon*, and *θεσις*, *poſitio*, *putting*. As a fruitful vine, a ſtately pile, an echoing vault, &c. Epithets are of great uſe and conveniency among poets and orators, who ſupply in epithets what they want in other requiſites. Card. Perron even blames Homer on the head of epithets, obſerving, that he frequently hooks in epithets without any ſenſe or ſignificancy at all, to help out his meaſures; and that he equips every hero with an epithet, not according to the exigence of the caſe, but the meaſure of the verſe.

EPITHET is alſo uſed for a ſurname, or a perſon's ſecond appellation. Epithets were anciently beſtowed very frankly, either on account of excellencies or defects of the body or mind; kings themſelves were not exempted from them, Hence thoſe epithets ſo frequent in hiſtory, as Edward Long-ſhanks, Richard Cœur de Lion, Edmund Iron-ſide, Richard Crook-back, John Lackland, &c. Nor have the French uſed their kings any better; witneſs their Charles the Simple Louis the Lazy, *feineant* (Ludovicus *nihil faciens*), Pepin the Short, Louis the Stammerer, *le begue*.

EPITOME, an abridgement, or a reduction of the principal matters of a larger book into a little compaſs. See ABRIDGEMENT. The word is Grek, *εϖιτομη*, formed of *εϖιτεμνειν*, *reſecare*, *to retrench*, *abridge*, or *cut off*.

EPLOYE', in heraldry. An *eagle eployé* is what in Engliſh we more uſually call an *eagle diſplayed*, or *a ſpread eagle*.

EPOCHA, in chronology, a term or fixed point of time, whence the ſucceding years are numbered or accounted.

Different epochas obtain in different nations; and no wonder; for there being no aſtronomical conſideration to render one preferable to another, their conſtitution is purely arbitrary. That principally regarded among Chriſtians, is, the epocha of the nativity or incarnation of Jeſus Chriſt; that of the Mahometans, the Hegira: that of the Jews, &c. the creation of the world; that of the ancient Greeks, the Olympiads; that of the Romans, the building of the city; that of the ancient Perſians and Aſſyrians, the Epocha of Nabonaſſar, &c. The doctrine and uſe of epochas is of very great extent in chronology.

EPOCHA *of Chriſt*, or *of our Lord*, is the vulgar epocha throughout Europe, commencing from the ſuppoſed time of our Saviour's nativity, December 25, or rather according to the uſual account, from his circumciſion, that is, from the firſt of January. In effect, the epocha of our Lord ſerves not only for the computation of the years elapſed ſince the epocha commenced, but even of thoſe before it.

The author of the vulgar epocha, or way of computing from Chriſt, is an abbot from Rome, one Dionyſius Exiguus, by nation a Scythian, who flouriſhed under Juſtinian about the year 507, or, according to others, 527, though this Dionyſius borrowed the hint from Pandorus, an Egyptian monk. Till his time, the generality of Chriſtians computed their years either from the building of Rome, or according to the order of the emperors and conſuls, and other ways in uſe with the people among whom they lived. This diverſity occaſioned a great diſtraction between the churches of the Eaſt and Weſt; Dionyſius, to compoſe the ſame, firſt propoſed a new form of the year, with a new general æra, which in a few years time was generally admitted. Dionyſius began his account from the conception or incarnation, by us popularly called Lady day, or the Annunciation; which method obtained in the dominions of Great Britain till the year 1752, before which time the Dionyſian and Engliſh epocha was the ſame; but in that year the Gregorian calendar having been admitted by act of parliament, they now reckon from the firſt of January, as they do in the other countries of Europe, except in the court of Rome, where the epocha of the incarnation ſtill obtains for the date of their bulls.

EPOCHA *of the Creation*, *orbis conditi*, according to the computation of the Jews, called alſo the Jewiſh epocha, is the year of the Julian period 953, anſwering to the year before Chriſt 3761, and commencing on the ſeventh day of October. This epocha is ſtill in uſe among the Jews.

The EPOCHA *of the Creation*, uſed by the Greek hiſtorian, is the year before the Julian period, 787, anſwering to the year before Chriſt 5500.

EPOCHA *of the Hegira*, or *Mahometan* EPOCHA, is the year of the Julian period 5335, anſwering to the year of Chriſt 622. It commences on the 16th of July, the day of Mahomet's flight from Mecca to Medina. This epocha is uſed by the Turks and Arabs, and even all who profeſs the Mahometan faith.

EPODE, Εϖοδος, in lyric poetry, the third or laſt part of the ode; the ancient ode, or ſong, being divided into ſtrophe, antiſtrophe, and epode.

EPOMIS, Εϖωμις, in anatomy, the upper part of the ſhoulder reaching up to the neck. See DELTOIDES.

EPOPOEIA, Εϖοϖοιια, in poetry, the hiſtory, action, or fable, that makes the ſubject of an epic poem. The word is derived from the Greek *εϖος*, *carmen*, *verſe*, and *ϖοιεω*, *facio*, *I make*.

EPSOM *Salt*. What we now meet with, in the ſhops of chymiſts, under this name, is no other than a ſalt made from the bittern, or remaining brine, after the making of common ſalt; but when the world was firſt made acquainted with a purging ſalt, under this name, it was truly what its name expreſſed, being really made from the purging waters of that place. This ſalt is bitter and of a ſtrongly purging quality, and, when ſuffered to ſhoot freely, and its cryſtals at a due diſtance, it always formed them into rectangular priſms, with four parallelogrammic planes; by this, and by divers other properties, it appears evidently different from all other ſalts known at that time. It was ſuppoſed to partake of the nature of alum, and the waters of the place were called aluminous waters; but Dr. Grew has evidently proved the error of that opinion: others ſuppoſed this ſalt the ſame thing with the ſalt of lime, or the nitre of old walls, but this was equally erroneous. The beſt method of taking it was found to be diſſolving it in a proper quantity of its own water; by this means the water was made to work both more quickly and more effectually; and it proved of great ſervice in diſorders of the ſtomach, as want of appetite, and the like; and in colics, diabetes, the ſcurvy, and rheumatiſm, and many other chronic diſeaſes. Phil. Tranſ. N°. 216. p. 76.

Mr. Boulduc has given much the ſame deſcription of the manner of making Epſom ſalt as Mr. Brown had done in Phil. Tranſ. N°. 37. § 10. and N°. 378. § 11. that it is the ſalt which cryſtallizes, after boiling to a due conſiſtence the bittern, which is the liquor remaining in the ſalt-pans, after the ſea-ſalt is ſeparated. See Mem. Acad. Scienc. 1731.

EPSOM *Water*. This is a water eaſily imitated by art, i. e. by only diſſolving half an ounce of Epſom ſalt in a quart of pure water, made ſomewhat briſk or quick by a few drops of ſpirit of vitriol and oil of tartar, ſo as to let the alkali prevail. Shaw's Lectures, p. 90.

EQUABLE *Motion*, is that whereby the moveable body proceeds with the ſame continued velocity; neither accelerated, nor retarded.

EQUAL, a term of relation between two or more things of the ſame magnitude, quantity, or quality. Mathematicians ſpeak of equal lines, angles, figures, circles, ratios, ſolids, &c.

EQUALITY, that agreement between two or more things, whereby they are denominated equal.

Equality, *ratio*, or proportion of, in geometry, is that between two equal numbers, or quantities.

Equality, in algebra, is a compariſon of two quantities, that are equal, both really, and repreſentatively, i. e. which are ſo both in effect and letters. A compariſon of two quantities, equal in effect, but unequal in letters, to render them equal, is called an equation.

EQUANIMITY, in ethics, denotes an even, uniform temper of mind, amidſt all the varieties and revolutions of time and chance. This virtue, together with prudence, forms the character which Horace gives of Ariſtippus:

> *Omnis Ariſtippum decuit color & ſtatus & res.*

EQUATION, or Æquation, in algebra, an expreſſion of the ſame quantity, in two different, that is, diſſimilar, but equal terms or denominations. See Syſtem of Algebra, for definition, Sect. I. for practical illuſtration, Sect. V. VI. and VII.

EQUATOR, or Æquator, in geography, a great circle of the ſphere, equally diſtant from the two poles of the world, or having the ſame poles with thoſe of the world. Such is the circle Æ, *Fig.* 3, 4, Plate II. its poles being N and S. It is called the equator, becauſe when the ſun is in it, the days and nights are equal; whence alſo it is called the the equinoctial; and when drawn on maps and planiſpheres, the equinoctial line, or ſimply, the line. Every point of the equator is a quadrant's diſtance from the poles of the world; whence it follows, that the equator divides the ſphere into two hemiſpheres, in one of which is the northern, and in the other the ſouthern pole.

EQUATOREAL, univerſal, in aſtronomy, is the name of an excellent inſtrument, made by Mr. Adams, an ingenious philoſophical inſtrument maker in London. For a particular deſcription of this inſtrument, ſee Syſtem of Astronomy, ſect. XVI. For the repreſentation of it, ſee Plate I.

EQUERRY, an officer of ſtate, under the maſter of the horſe. There are five equerries who ride abroad with his majeſty; for which purpoſe they attend monthly, one at a time, and are allowed a table. As to the equerries of the crown table, they have this diſtinct appellation, as being employed in mounting, managing, and breaking the ſaddle horſes, for his majeſty's uſe, and holding his ſtirrup.

EQUES *Auratus*, is uſed to ſignify a knight bachelor, called auratus, q. d. gilt, becauſe anciently none but knights might gild or beautify their armour, or other habiliments of war, with gold.

EQUESTRIS, Equestrian, a term chiefly uſed in the phraſe, *equeſtrian ſtatue*, which ſignifies a ſtatue repreſenting a perſon mounted on horſeback. The word is formed of the Latin, *eques, knight, horſeman,* of *equus, horſe.*

EQUESTRIAN *Games, ludi equeſtres,* among the Romans, horſeraces, of which there are five kinds, the prodromus, or plain horſe race, the chariot race, the decurſory race about funeral piles, the *ludi ſemirales*, and the *ludi neptunales*.

Equestrian *Order*, among the Romans, ſignified the order of knights or equites.

EQUIANGULAR, or Æquiangular, in geometry, is applied to figures whoſe angles are all equal.

EQUIDISTANT, or Æquidistant, in geometry, a term of relation between two things which are every where at an equal or the ſame diſtance from each other. Thus, parallel lines are ſaid to be equidiſtant, as they neither approach nor recede.

EQUILATERAL, or Æquilateral, of *æquus, equal,* and *latus, ſide,* is applied to any thing whoſe ſides are all equal. Thus, an equilateral triangle is that whoſe ſides are all of equal length. In an equilateral triangle all the angles are likewiſe equal. All regular poligons and regular bodies are equilateral.

EQUILIBRIUM, or Æquilibrium, in mechanics, a term implying an exact equality of momentum or force between two bodies compared with each other; and this takes place when their directions are equally oppoſite, and their maſſes are reciprocally proportional to the velocities with which they tend to move. A balance is in equilibrio when the two ends are ſo exactly poiſed that neither of them aſcends or deſcends, but both retain their parallel poſition to the horizon. From this circumſtance the word is originally taken, as being a compound of *æquus, equal,* and *libra, balance*; whence we frequently uſe the word balance in lieu thereof.

Equilbrium is alſo uſed figuratively on other occaſions. A painter muſt take care to obſerve the equilibrium of his figures, i. e. diſpoſe them well on their centre of gravity, that they may not ſeem ill-ſupported, or ready to tumble. Thus, e. gr. if one arm be moved forward, the other muſt be proportionally backward to poiſe the figure.

EQUIMULTIPLE, in arithmetic and geometry, is applied to ſimple magnitudes when multiplied equally, i. e. by equal quantities or multipliers. Thus, taking A as many times as B, or multiplying them equally, there will ſtill remain the ſame ratio between the magnitudes thus multiplied as between the primitive magnitudes before multiplication.

EQUINOCTIAL, or Æquinoctial, in aſtronomy, a great and immoveable circle of the ſphere, under which the equator moves in its diurnal motion. The equinoctial, or equinoctial line, is ordinarily confounded with the equator; but there is a difference, the equator being moveable, and the equinoctial immoveable; and the equator being drawn about the convex ſurface of the ſphere, but the equinoctial on the concave ſurface of the magnus orbis. Whenever the ſun, in his progreſs through the ecliptic, comes to this circle, it makes equal days and nights all around the globe; as then riſing due eaſt and ſetting due weſt, which he never does at any other time of the year. And hence the denomination from *æquus* and *nox, night, quia æquat diem nocti.*

Equinoctial *Dial*, is that whoſe plane lies parallel to the equinoctial. See Treatiſe on Dialling, Sect. VI. Article 12.

EQUINOX, or Æquinox, in aſtronomy, the time when the ſun enters one of the equinoctial points. The equinoxes happen when the ſun is in the equinoctial circle; when of conſequence the days are equal to the nights throughout the world, which is the caſe twice a year, viz. about the 20th of March and the 23d of September, the firſt of which is the *vernal*, and the ſecond the *autumnal equinox*.

EQUIPAGE, in the military art, denotes all ſorts of utenſils, artillery, &c. neceſſary for commencing and proſecuting with eaſe and ſucceſs any military operations. Camp and field equipage conſiſts of tents, kitchen furniture, ſaddle-horſes, baggage waggons, bat-horſes, &c.

EQUITY, in a general ſenſe, the virtue of treating all other men according to reaſon and juſtice, or as we would gladly be treated ourſelves when we underſtand aright what is our due.

Equity, in juriſprudence, is defined a correction or qualification of the law, generally made in that part wherein it faileth, or is too ſevere. It likewiſe ſignifies the extenſion of the words of the law to caſes unexpreſſed, yet having the ſame reaſon; ſo that where one thing is enacted by ſtatute, all other things are enacted that are of the like degree. For example, the ſtatute of Glouc. gives action of waſte againſt him that holds lands for life or years; and, by the equity thereof, a man ſhall have action of waſte againſt a tenant that holds but for one year, or one half-year, which is without the words of the act, but within the meaning of it; and the words that enact the one, by equity enact the other. So that equity is of two kinds. The one abridges and takes from the letter of the law: the other enlarges and adds to it; and ſtatutes may be conſtrued according to equity, eſpecially where they give remedy for wrong, or are for expedition of juſtice. Equity ſeems to be the interpoſing law of reaſon, exerciſed by the lord chancellor in extraordinary matters to do equal juſtice, and, by ſupplying the defects of the law, gives remedy in all caſes. See Blackst. Comment. vol. i. 61, 91. vol. iii. 49, 429, 436. vol. iv. 435.

Equity *of Redemption*, on mortgages, is that right which a mortgager has of redeeming his eſtate upon payment of the money borrowed. If where money is due on a mortgage, the mortgagee is deſirous to bar the equity of redemption, he may oblige the mortgager either to pay the money, or be foreclosed of his equity; which is done by proceedings in the court of chancery. But the chancery cannot ſhorten the time of payment of the mortgage money, where it is limited by expreſs covenant, though it may lengthen it; and then upon non-payment, the practice is to foreclose the equity of redemption of the mortgager. 2 Vent. 364.

To foreclose the equity, a bill in chancery is exhibited, to which an anſwer is put in and a decree being obtained, a maſter in chancery is to certify what is due for principal, intereſt, and coſts, which are to be prefixed by the decree, whereupon the premiſes are to be re-conveyed to the mortgager; or, in default of payment, the mortgager is ordered to be foreclosed from all equity of redemption, and to convey the premiſes abſolutely to the mortgagee. By ſtat. 7 Geo. II. cap. 20, after payment or tender by the mortgager of principal, intereſt, and coſts, the mortgagee can maintain no ejectment, but may be compelled to re-aſſign his ſecurities.

EQUIVALENT, an appellation given to things which agree in nature or other circumſtance; as *force, virtue,* &c.

EQUIVOCAL *Terms*, or *Words*, among logicians, are thoſe which have a doubtful or double meaning. According to Mr. Locke, the doubtfulneſs and uncertainty of words has its cauſe more in the ideas themſelves, than in any incapacity of the words to ſignify them; and might be avoided, would people always uſe the ſame term to denote the ſame idea, or collection of ideas: but, adds he, it is hard to find a diſcourſe on any ſubject where this is the caſe; a practice which can only be imputed to folly, or great diſhoneſty.

EQUIVOCATION, *Æquivocatio*, the uſing a term or expreſſion that has a double ſignification. Equivocations are expedients to ſave telling the truth, and yet without telling a falſity.

EQUULEUS, or Eculeus, in antiquity, a kind of rack, or engine of torture, uſed for extorting the truth; at firſt chiefly on ſlaves, but afterwards turned againſt the Chriſtians. The patient's arms and legs being faſtened on the equuleus with cords, he was hoiſted aloft, and extended in ſuch manner that all his bones were diſlocated. In this ſtate, red-hot plates were applied to his body,

body; and he was alſo goaded in the ſides with an iron-forked inſtrument, called ungula. The equuleus was of wood, and had holes at certain diſtances, with a ſcrew, by which the criminal was ſtretched to the third, ſometimes to the fourth or the fifth hole: at intervals, the ſcrew was ſlackened again, by which he had ſome reſpite; but then he was tormented with queſtions. The equuleus in more antient times was conſtructed in the form of a horſe; the criminal was laid on his back, and his arms were turned under the breaſt of the equuleus, his hands were bound and his feet ſtretched out towards his tail. A rope faſtened to the feet was made to paſs over a ſmaller pulley between the hind legs of the equuleus, and made to coil over another larger pulley fixed under the belly by means of a handle, which the executioner turned round till all the bones, &c. were diſlocated. Phil. Tranſ. vol. viii. part iv. p. 32, &c.

EQUUS, the horſe, a genus of quadrupeds belonging to the order of belluæ, in the claſs Mammalia. This genus comprehends the horſe, the aſs, and the zebra; they have ſix erect and parallel fore-teeth in the upper jaw, and ſix ſomewhat prominent ones in the under jaw; the dog teeth are ſolitary, and at a conſiderable diſtance from the reſt; and the feet conſiſt of an undivided hoof. The horſe is a domeſtic animal; and the figure and dimenſions of his body are ſo well known, that a general deſcription is altogether unneceſſary. We ſhall therefore confine ourſelves to the natural hiſtory of this noble animal.

The horſe, in a domeſtic ſtate, is a bold and fiery animal; equally intrepid as his maſter, he faces danger and death with ardour and magnanimity. He delights in the noiſe and tumult of arms, and ſeems to feel the glory of victory: he exults in the chaſe; his eyes ſparkle with emulation in the courſe. But though bold and intrepid, he is docile and tractable: he knows how to govern and check the natural vivacity and fire of his temper. He not only yields to the hand, but ſeems to conſult the inclination of his rider. Conſtantly obedient to the impreſſions he receives, his motions are entirely regulated by the will of his maſter. He in ſome meaſure reſigns his very exiſtence to the pleaſure of man. He delivers up his whole powers; he reſerves nothing; he will rather die than diſobey. Who could endure to ſee a character ſo noble abuſed! who could be guilty of ſuch groſs barbarity!

This character, though natural to the animal, is in ſome meaſure the effect of education. His education commences with the loſs of liberty, and it is finiſhed by conſtraint. The ſlavery of the horſe is ſo ancient and ſo univerſal, that he is but rarely ſeen in a natural ſtate. Several ancient writers talk of wild horſes, and even mention the places where they were to be found. Thoſe of America were originally tranſported from Europe by the Spaniards; for this ſpecies of animals did not exiſt in the new world. The Spaniards carried over a great number of horſes, left them in different iſlands, &c. with a view to propagate that uſeful animal in their colonies. Theſe have multiplied incredibly in the vaſt deſarts of thoſe thinly peopled countries, where they roam at large, without any reſtraint.

The horſe has not only a grandeur in his general appearance, but there is the greateſt ſymmetry and proportion in the different parts of his body. The regularity and proportion of the different parts of the head gives him an air of lightneſs, which is well ſupported by the ſtrength and beauty of his cheſt. He erects his head, as if willing to exalt himſelf above the condition of other quadrupeds: his eyes are open and lively; his ears are handſome, and of a proper height; his mane adorns his neck, and gives him the appearance of ſtrength and boldneſs.

At the age of two years, or two years and a half, the horſe is in a condition to propagate; and the mare, like moſt other females, is ready to receive him ſtill ſooner. But the foals produced by ſuch early embraces are generally ill-made and weakly. The horſe ſhould never be admitted to the mare till he is four or four and a half; this is only meant with regard to draught horſes. Fine horſes ſhould not be admitted to the mare before they be ſix years old; and Spaniſh ſtallions not till ſeven. The mares are generally in ſeaſon from the beginning of March to the end of April; but their chief ardour for the horſe laſts but about 15 or 20 days, and this critical ſeaſon ſhould always be embraced. The ſtallions ought to be ſound, well made, vigorous, and of a good breed. For fine ſaddle-horſes, foreign ſtallions, as Arabians, Turks, Barbs, and Andalouſians, are preferable to all others. Next to theſe, Britiſh ſtallions are the beſt; becauſe they originally ſprang from thoſe above-mentioned, and are very little degenerated. The ſtallions of Italy, and eſpecially the Neapolitans, are very good. The beſt ſtallions for draught or carriage horſes, are thoſe of Naples, Denmark, Holſtein, and Freezeland. The ſtallions for ſaddle horſes ſhould be from 14 to 15 hands high, and for draught horſes at leaſt 15 hands. Neither ought the colour of ſtallions to be over-looked; as a fine black, grey, bay, ſorrel, &c. Beſides theſe external qualities, a ſtallion ought to have courage, tractability, ſpirit, agility, a ſenſible mouth, ſure limbs, &c. Theſe precautions in the choice of a ſtallion are the more neceſſary, becauſe he has been found by experience to communicate to his offspring, almoſt all his good or bad qualities, whether natural or acquired.

The mare contributes leſs to the beauty of her offspring than the ſtallion; but ſhe contributes perhaps more to their conſtitution and ſtature: for theſe reaſons, it is neceſſary that the mares for breed be perfectly ſound, and make good nurſes. For elegant horſes, the Spaniſh and Italian mares are beſt, but, for draught horſes, thoſe of Britain and Normandy are preferable. However, when the ſtallions are good, the mares of any country will produce fine horſes, provided they be well made and of a good breed.

Mares go with young eleven months and ſome days. They bring forth ſtanding; contrary to the courſe of moſt other quadrupeds, who lie during this operation. They continue to bring forth till the age of 16 or 18 years; and both horſes and mares live between 25 and 30 years. Horſes caſt their hair once a year, generally in the ſpring, but ſometimes in the autumn. At this time they are weak, and require to be better fed and taken care of than at any other ſeaſon.

In Perſia, Arabia, and moſt Eaſtern countries, they never geld their horſes, as is done in Europe and China. This operation greatly diminiſhes their ſtrength; courage, and ſpirits; but it makes them good humoured, gentle, and tractable. With regard to the time of performing this operation, the practice of different countries is different: ſome geld their horſes when a year old, and others at 18 months. But the beſt and moſt general practice is to delay the operation till they be two years old at leaſt; becauſe, when the gelding is delayed for two years or more, the animals retain more of the ſtrength and other qualities which naturally belong to the male.

As the utility of horſes ſurpaſſes that of all other domeſtic animals, it may be of uſe to ſubjoin ſome marks by which the age and other properties of horſes may be diſtinguiſhed.

In old horſes, the eye pits are generally deep; but this is only an equivocal mark, being alſo found in young horſes begot by old ſtallions. The moſt certain knowledge of the age is to be obtained from the teeth. Of theſe a horſe has 40; 24 grinders or double teeth, four tuſhes, and 12 fore teeth: mares have no tuſhes, or at leaſt very ſhort ones. It is not from the grinders that we know the age; it is diſcovered firſt by the fore-teeth, and afterwards by the tuſhes. The 12 fore-teeth begin to ſhoot within 12 days after the colt is foaled. Theſe firſt, or foal teeth, are round, ſhort, not very ſolid, and are caſt at different times, to be replaced by others. At the age of two years and a half, the four middle fore-teeth are caſt, two in the upper jaw, and two in the lower. In one year more, four others drop out, one on each ſide of the former, which are already replaced. When he is about four years and a half old, he ſheds four others, and always next to thoſe which have fallen out and been replaced. Theſe four foal teeth are replaced by four others, but are far from growing ſo faſt as thoſe which replaced the eight former, and are called the corner teeth; they replace the four laſt foal-teeth, and by theſe the age of a horſe is diſcovered. They are eaſily known, being the third both above and below, counting from the middle of the jaw. They are hollow, and have a black mark in their cavity. When the horſe is four years and a half old, they are ſcarce viſible above the gum, and the cavity is very ſenſible: at ſix and a half, they begin to fill; and the mark continually diminiſhes and contracts till ſeven or eight years, when the cavity is quite filled up, and the black ſpot effaced. After eight years, theſe teeth ceaſing to afford any knowledge of the age, it is judged of by the tuſhes: which are four teeth adjoining to thoſe laſt mentioned; and, like the grinders, are not preceded by any other teeth. The two in the lower jaw uſually begin to ſhoot at three years and a half, and thoſe of the upper jaw at four; continuing very ſharp-pointed till ſix. At 10, the upper ſeem blunted, worn out, and long, the gum contracting itſelf as its years increaſe; the barer therefore they are, the older is the horſe. From 10 to 13 or 14 years, little can be ſeen to indicate the age; but at that time ſome hairs of the eye brows begin to turn grey. The age of a horſe may be alſo known, though leſs accurately, by the bars in his mouth, which wear away as he advances in years.

When the horſe is without blemiſh, the legs and thighs are clean, the knees ſtraight, the ſkin and ſhank thin, and the back ſinew ſtrong and well braced. The ſinews and the bones ſhould be ſo diſtinct, as to make the legs appear thin and lathy, not full and round. The paſtern joints ſhould never be large and round; nor muſt there be any ſwelling near the coronet. The hocks ſhould be lean and dry, not puffed up with wind. With regard to the hoof, the coronet ſhould be equally thick, and the horn ſhining and greyiſh. A white horn is a ſign of a bad foot, for it will wear out in a ſhort time; and likewiſe when the horn is thin, it is liable to be ſpoiled in ſhoeing, and by travelling hard on ſtony grounds. This is beſt known when the ſhoe is taken off; for then the verge all round the ſole will appear thin, and the horſe will wince at the leaſt touch of the pincers.

A ſtrong foot has the fibres of the hoof very diſtinct running in a direct line from the coronet to the toe, like the grain of wood. In this caſe, care muſt be taken to keep the foot moiſt and pliable. The greateſt inconvenience attending a hard ſtrong foot, is its being ſubject to rifts and fiſſures, which cleave the hoof quite through ſometimes from the coronet down to the bottom.

A narrow heel is likewiſe a defect; and when it is not above two fingers in breadth, the foot is bad. A high heel cauſes a horſe to trip and ſtumble often; and the low one, with long yielding paſterns, is very apt to be worn quite away on a journey. Too large a foot in proportion to the reſt of the body, renders a horſe weak and heavy.

The head of a horſe ſhould be ſmall, and rather lean than fleſhy. The ſhoulders ſhould be pretty long; the withers thin, and enlarge gradually from thence downwards; but ſo as to render his breaſt neither too narrow nor too groſs. A thick-ſhouldered horſe ſoon tires, and trips and ſtumbles every minute; eſpecially if he has a thick large neck at the ſame time. When the breaſt is ſo narrow that the fore-thighs almoſt touch, they are never good for much. A horſe of a middle ſize ſhould have the diſtance of five or ſix inches between his fore-thighs, and there ſhould be leſs diſtance between his feet than his thighs near the ſhoulders when he ſtands upright. The body or carcaſe of a horſe ſhould be of a middling ſize in proportion to his bulk, and the back ſhould ſink a little below the withers; but the other parts ſhould be ſtraight, and no higher behind than before. He ſhould alſo be home-ribbed; but the ſhort ribs ſhould not approach too near the haunches, and then he will have room to fetch his breath. When a horſe's back is ſhort in proportion to his bulk, and yet otherwiſe well limbed, he will hold out a journey, though he will travel ſlow. When he is tall, at the ſame time with very long legs, he is but of little value.

The wind ſhould never be overlooked in the choice of a horſe; and it may eaſily be known by his flanks, if he is broken-winded, when he ſtands quiet in the ſtable; becauſe he always pinches them in with a very ſlow motion, and drops them ſuddenly. A thick-winded horſe fetches his breath often, and ſometimes rattles and wheezes. This may be always diſcovered when he is put to briſk exerciſes. The temper of a horſe ſhould always be obſerved; a vicious horſe generally lays his ears cloſe to his pole, ſhews the whites of his eyes, and looks ſullen and dogged. An angry horſe may be known by his frowning looks; and he generally ſeems to ſtand in a poſture of defence. When he is very vicious, he pays no regard to the groom that feeds him: however, ſome horſes that are ticklish will lay back their ears, and yet be of a good diſpoſition. A fearful horſe is apt to ſtart, and never leaves it off till he is old and uſeleſs. A fretful horſe is very unfit for a journey: and you may diſcover his temper as ſoon as he gets out of the ſtable. A dull, heavy, ſluggiſh horſe may be eaſily known, whatever tricks are uſed to rouſe his ſpirits.

The breed of horſes in Great Britain is as mixed as that of its inhabitants; the frequent introduction of foreign horſes has given us a variety, that no ſingle country can boaſt of; moſt other countries produce only one kind; while ours, by a judicious mixture of the ſeveral ſpecies, by the happy difference of our ſoils, and by our ſuperior ſkill in management, may triumph over the reſt of Europe, in having brought each quality of this noble animal to the higheſt perfection. In the annals of Newmarket, may be found inſtances of horſes that have literally outſtripped the wind, as the celebrated M. Condamine has lately ſhewn in his remarks on thoſe of Great Britain. Childers is an amazing inſtance of rapidity; his ſpeed having been more than once extended equal to 82½ feet in a ſecond, or near a mile in a minute: the ſame horſe has alſo run the round courſe at Newmarket, (which is about 400 yards leſs than four miles) in ſix minutes and 40 ſeconds; in which caſe his fleetneſs is to that of the ſwifteſt barb, as four to three; the former, according to Dr. Maty's computation, covering at every bound a ſpace of ground equal in length to 23 feet royal, the latter only that of 18½ feet royal.

Horſes of this kind derive their origin from Arabia; the ſeat of the pureſt and moſt generous breed. The ſpecies uſed in hunting, is a happy combination of the former with others ſuperior in ſtrength, but inferior in point of ſpeed and lineage; an union of both is neceſſary; for the fatigues of the chace muſt be ſupported by the ſpirit of the one, as well as by the vigour of the other. No country can bring a parallel to the ſtrength and ſize of our horſes deſtined for the draught; or to the activity and ſtrength united of thoſe that form our cavalry. In our capital there are inſtances of ſingle horſes that are able to draw on a plan, for a ſmall ſpace, the weight of three tuns, but could with eaſe, and for a continuance, draw half that weight. The pack horſes of Yorkſhire, employed in conveying the manufactures of that county to the moſt remote parts of the kingdom, uſually carry a burden of 420 pounds; and that indifferently over the higheſt hills of the north, as well as the moſt level roads. But the moſt remarkable proof of the ſtrength of our Britiſh horſes, is to be drawn from that of our mill-horſes; ſome of theſe will carry at one load 13 meaſures, which at a moderate computation of 70 pounds each, will amount to 910; a weight ſuperior to that which the leſſer ſort of camels will bear; this will appear leſs ſurpriſing, as theſe horſes are by degrees accuſtomed to the weight; and the diſtance they travel no greater than to and from the adjacent hamlets.

Our cavalry, in the late campaigns, (when they had opportunity) ſhewed over thoſe of our allies, as well as of the French, a great ſuperiority both of ſtrength and activity; the enemy was broken through by the impetuous charge of our ſquadrons; while the German horſes, from their great weight and inactive make, were unable to ſecond our efforts; though thoſe troops were actuated by the nobleſt ardour. The preſent cavalry of this iſland only ſupports its ancient glory. It was eminent in the earlieſt times: our ſcythed chariots, and the activity and good diſcipline of our horſes, even ſtruck terror into Cæſar's legions; and the Britons, as ſoon as they became civilized enough to coin, took care to repreſent on their money the animal for which they were ſo celebrated. It is now impoſſible to trace out this ſpecies; for thoſe which exiſt among the *indigenæ* of Great Britain, ſuch as the little horſes of Wales and Cornwal, the hobbies of Ireland, and the ſhelties of Scotland, though admirably well adapted to the uſes of thoſe countries, could never have been equal to the work of war: but probably we had even then a larger and ſtronger breed in the more fertile and luxuriant parts of the iſland. Thoſe we employ for that purpoſe, or for the draught, are an offspring of the German or Flemiſh breed, meliorated by our ſoil and a judicious culture. The Engliſh were ever attentive to an exact culture of theſe animals; and in very early times ſet a high value on their breed. The eſteem that our horſes were held in by foreigners ſo long ago as the reign of Athelſtan, may be collected from a law of that monarch, prohibiting their exportation, except they were deſigned as preſents. Theſe muſt have been the native kind, or the prohibition would have been needleſs; for our commerce was at that time too limited to receive improvement from any but the German kind, to which country their own breed could be of no value.

But when our intercourſe with the other parts of Europe was enlarged, we ſoon laid hold of the advantages this gave of improving our breed. Roger de Beleſme, earl of Shrewſbury, is the firſt that is on record; he introduced the Spaniſh ſtallions into his eſtate in Powiſland, from which that part of Wales was for many ages celebrated for a ſwift and generous race of horſes. Giraldus Cambrenſis, who lived in the reign of Henry II. takes notice of it; and Michael Drayton, cotemporary with Shakeſpear, ſings their excellence in the ſixth part of his Polyolbion. This kind was probably deſtined to mount our gallant nobility, or courteous knights for feats of chivalry, in the generous conteſts of the tilt-yard. From theſe ſprung, to ſpeak the language of the times, the flower of courſers, whoſe elegant form added charms to the rider, and whoſe activity and managed dexterity gained him the palm in that field of gallantry and romantic honour.

The increaſe of our inhabitants, and the extent of our manufactures, together with the former neglect of internal navigation to convey thoſe manufactures, multiplied the number of our horſes: an exceſs of wealth, before unknown in theſe iſlands, increaſed the luxury of carriages, and added to the neceſſity of an extraordinary culture of theſe animals: their high reputation abroad has alſo made them a branch of commerce, and proved another cauſe of their vaſt increaſe.

As no kingdom can boaſt of parallel circumſtances, ſo none can vie with us in the number of theſe noble quadrupeds. It would be extremely difficult to gueſs at the exact amount of them, or to form a periodical account of their increaſe: the number ſeems very fluctuating. William Fitz-Stephen relates, that in the reign of king Stephen, London alone poured out 20,000 horſemen in the wars of thoſe times: yet we find, that, in the beginning of queen Elizabeth's reign, the whole kingdom could not ſupply 2000 horſes to form our cavalry: and even in the year 1588, when in the moſt imminent danger from the Spaniſh invaſion, all the cavalry which the nation could then furniſh amounted only to 3000. To account for this difference we muſt imagine, that the number of horſes which took the field in Stephen's reign was no more than an undiſciplined rabble; the few that appeared under the banners of Elizabeth, a corps well formed, and ſuch as might be oppoſed to ſo formidable an enemy as was then expected: but ſuch is their preſent increaſe, that, in the late war, the number employed was 13,575; and ſuch is our improvement in the breed of horſes, that moſt of thoſe which are uſed in our waggons and carriages of different kinds, might be applied to the ſame purpoſe: of thoſe, our capital alone employs near 22,000.

The all-wiſe Creator hath finely limited the ſeveral ſervices of domeſtic animals towards the human race; and ordered that the parts of ſuch, which in their lives have been the moſt uſeful, ſhould after death contribute the leaſt to our benefit. The chief uſe that the *exuviæ* of the horſe can be applied to, is for collars, traces, and other parts of the harneſs; and thus, even after death, he preſerves ſome analogy with his former employ. The hair of the mane is of uſe in making wigs; of the tail, in making the bottoms of chairs, floor-cloths, and cords; and to the angler in making lines.

TECHNICAL DESCRIPTION OF THE PARTS OF A HORSE.

The fore Part. 1. The forehead. 2. The temples. 3. Cavity above the eye. 4. The jaw. 5. The lips. 6. The noſtrils. 7. The tip of the noſe. 8. The chin. 9. The beard. 10. The neck. 11. The mane. 12. The fore top. 13. The throat. 14. The withers. 15. The ſhoulders. 16. The cheſt. 17. The elbow. 18. The arm. 19. The plate vein. 20. The cheſnut. 21. The knee. 22. The ſhank. 23. The main tendons. 24. The fetlock joint. 25. The fetlock. 26. The paſtern. 27. The coronet. 28. The hoof. 29. The quarters. 30. The toe. 31. The heel. *The Body.* 32. The reins. 33. The fillets. 34. The ribs. 35. The belly. 36. The flanks. *The hind Part.* 37. The rump. 38. The tail. 39. The buttocks.

40. The haunches. 41. The ſtifle. 42. The thighs. 43. The hock 44. The kerb. 45. The point of the hock. For a repreſentation ſee the Plates of Quadrupeds.

For the breeding, rearing, &c. of horſes, ſee the articles Horse, and Stallion; for the method of training and managing them, ſee Horsemanship; and for their diſeaſes, cure, &c. See Farriery.

In the Syſtem of Farriery *will be introduced Five Plates, repreſenting the Oſteology and Myology of this uſeful Animal. Two ſheets will be appropriated to illuſtrate them; and we flatter ourſelves they will be highly acceptable to our Readers, and ſtamp an additional value on the Work, as they will contain, though in ſo ſmall a compaſs, the whole of that ineſtimable production,* Mr. Stubb's Anatomy of the Horſe, *which ſells for* 5 Guineas.

The Aſs is likewiſe a domeſtic animal, and eaſily diſtinguiſhed from the horſe at firſt ſight; we never confound theſe two animals, even though they ſhould happen to be of the ſame colour and ſtature. However, when we view the different parts of the aſs, whether the external or internal, and compare them with the correſponding parts of the horſe, the reſemblance of theſe parts is ſo perfect, that we are ſurpriſed to find the individuals ſo different and ſo eaſily diſtinguiſhable by the eye. From this circumſtance, ſome naturaliſts have conſidered the aſs and the horſe to be of the ſame ſpecies of animals; and that the ſmall differences between them are accidental, or owing to the influence of climate, culture, &c. Linnæus's ſpecific mark of the horſe is, that the whole tail is covered with long hair; and his ſpecific mark of the aſs is, that the tail has long hair only towards the point, and a black croſs over the ſhoulders. On the other hand, when we conſider the differences in the temper, the manners and diſpoſitions of theſe two animals, and, above all, the impoſſibility of mixing them ſo as to produce a common or intermediate ſpecies capable of propagating and tranſmitting in the ſame manner as other diſtinct ſpecies; the notion that the horſe and the aſs are the ſame ſpecies will appear to be without any ſolid foundation. Beſides, the aſs differs materially from the horſe in the thickneſs of the head, the length of the ears, the hardneſs of the ſkin, and in the voice, the diſpoſitions, the manner of drinking, &c. With regard to animals, there is perhaps but one permanent and uniform ſpecific diſtinction in nature: a male and female of different ſpecies may copulate, may produce a third animal reſembling both, but very different from either: but here nature has put a final ſtop to all further procreation; the third animal, although it be ſeemingly furniſhed with every thing neceſſary for propagating, remains for ever barren. Now, the horſe may be made to copulate with the aſs: a mule, or mixture of the two, is the fruit of the unnatural embrace: but the impregnation of a mule is found by experience to be altogether impoſſible.

The aſs, therefore, is a diſtinct ſpecies, and his race as ancient as that of the horſe. Why, then, ſhould this uſeful, patient, ſober animal be ſo much deſpiſed? We are apt to compare him, on every occaſion, with the horſe, and from this compariſon are led to very falſe and unfavourable concluſions. The horſe is educated with great care and expence; while the poor aſs, abandoned to the abuſe of the meaneſt ſervants, or the cruelty of children, inſtead of deriving benefit from inſtruction, loſes in effect his natural good qualities by the bad treatment he ſuffers. He is the ſport and buffet block of every ruſtic, who beat and overload him without mercy or diſcretion. They never conſider that the aſs would be the moſt uſeful, the beſt made, and moſt diſtinguiſhed of all animals, if there were no horſes in the world.

The aſs is as humble, patient, and tranquil, as the horſe is bold, ardent, and impetuous. He ſubmits with firmneſs, perhaps with magnanimity, to ſtrokes and chaſtiſement; he is temperate both as to the quantity and quality of his food: he contents himſelf with the rigid and diſagreeable herbage which the horſe and other animals leave to him, and diſdain to eat: he is more delicate with regard to his drink, never uſing water unleſs it be perfectly pure. As his maſter does not take the trouble of combing him, he often rolls himſelf on the turf among thiſtles, ferns, &c. without regarding what he is carrying, he lies down to roll as often as he can, ſeeming to reproach his maſter for neglect and want of attention.

When very young, the aſs is a gay, ſprightly, nimble, and gentle animal. But he ſoon loſes theſe qualities, probably by the bad uſage he meets with; and becomes lazy, untractable, and ſtubborn. When under the influence of love, he becomes perfectly furious. The affection of the female for her young is ſtrong: Pliny aſſures us, that when an experiment was made to diſcover the ſtrength of maternal affection in a ſhe aſs, ſhe run through the flames in order to come at her colt.

Although the aſs be generally ill uſed, he diſcovers a great attachment to his maſter; he ſmells him at a diſtance, ſearches the places and roads he uſed to frequent, and eaſily diſtinguiſhes him from the reſt of mankind. The aſs has a very fine eye, an excellent ſcent, and a good ear. When overloaded, he hangs his head, and ſinks his ears: when too much teazed or tormented, he opens his mouth and retracts his lips in a diſagreeable manner, which gives him an air of ridicule and deriſion. If you cover his eyes, he will not move another ſtep; if you lay him on his ſide, and place his head ſo that one eye reſts on the ground, and cover the other with a cloth, he will remain in this ſituation without making any attempt to get up. He walks, trots, and gallops in the ſame manner as the horſe; but all his motions are ſlower. Whatever be the pace he is going at, if you puſh him he inſtantly ſtops.

The cry of the horſe is known by the name of neighing; that of the aſs by braying, which is a long, diſagreeable noiſe, conſiſting of alternate diſcords from ſharp to grave and from grave to ſharp; he ſeldom cries but when preſſed with hunger or love: the voice of the female is clearer and more piercing than that of the male.

The aſs is leſs ſubject to vermin than other animals covered with hair; he is never troubled with lice, probably owing to the hardneſs and dryneſs of his ſkin; and it is probably for the ſame reaſon, that he is leſs ſenſible to the whip and ſpur than the horſe. The teeth of the aſs fall out and grow at the ſame age and in the ſame manner as thoſe of the horſe; and he has nearly the ſame marks in his mouth.

Aſſes are capable of propagating when two years old. The females are in ſeaſon during the months of May and June. The milk appears in the dugs ten months after impregnation: ſhe brings forth in the twelfth month, and always one at a time. Seven days after the birth, the ſeaſon of the female returns, and ſhe is again in a condition to receive the male. The colt ſhould be taken from her at the end of five or ſix months, that the growth and nouriſhment of the fetus may not be obſtructed. The ſtallion or jack aſs ſhould be the largeſt and ſtrongeſt that can be found; he ſhould be at leaſt three years old, and never ought to exceed ten. The aſs, like the horſe, takes three or four years in growing, and lives till he be 25 or 30: he ſleeps leſs than the horſe, and never lies down to ſleep but when exceſſively fatigued. He is more robuſt, and leſs ſubject to diſeaſes, than the horſe.

Travellers inform us that there are two ſorts of aſſes in Perſia; one of which is uſed for burdens, they being ſlow and heavy: the other is kept like horſes for the ſaddle; for they have ſmooth hair, carry their head well, and are much quicker in their motion; but when they ride them, they ſit nearer their buttocks than when on a horſe: they are dreſſed like horſes, and are taught to amble like them; but they generally cleave their noſtrils to give them more room for breathing. Dr. Ruſſel likewiſe tells us they have two ſorts in Syria; one of which is like ours, and the other very large, with remarkably long ears; but they are both put to the ſame uſe, which is, to carry burdens.

The Onager, or wild aſs, has, by ſome authors, been confounded with the zebra; but very improperly, for this laſt is a diſtinct ſpecies; for the onager is not ſtreaked like this, nor is his ſhape ſo beautiful. Wild aſſes are ſaid to be very ſwift of courſe; and when they ſee a man, they make a bound, and immediately fly away; inſomuch, that there is no taking of them, but by traps and gins. They have much the ſame ſhape as common aſſes; but they are of a brighter colour, and there runs a white liſt from the head to the tail. Of the hide of theſe aſſes, and particularly of that part next the rump, they make that excellent leather which we call ſhagreen, and which is put to ſo many curious uſes.

In America there were originally no aſſes at all, nor yet horſes: but they were carried thither long ago, at firſt by the Spaniards, and afterwards by other nations, where they have multiplied greatly; inſomuch, that, in ſome places, there are whole droves of them that run wild, and are very hard to be caught. Aſſes in general carry the heavieſt burdens in proportion to their bulk; and, as their keeping coſts little or nothing, it is a great wonder that they are not put to more uſes than they generally are among us. The fleſh of the common aſs is never eaten in theſe parts of the world; tho' ſome pretend their colts are tender, and not diſagreeable.

The Zebra. This animal has the figure and gracefulneſs of the horſe, joined to the ſwiftneſs of the ſtag. He is about 7 feet long, from the point of the muzzle to the origin of the tail, and about 4 feet high. The colour of his ſkin is beautiful and uniform, conſiſting of alternate parallel rings of black and white, diſpoſed in the moſt regular manner, as repreſented in the plate. He is generally leſs than the horſe, and larger than the aſs.

The zebra is found no where but in the eaſtern and ſouthern provinces of Africa, from Ethiopia to the Cape of Good Hope, and from the Cape of Good Hope to Congo. The Dutch have been at great pains to tame and uſe them for domeſtic purpoſes, but with little ſucceſs. He is hard-mouthed, and kicks when any perſon attempts to touch or come near him. He is reſtleſs and obſtinate as a mule: but perhaps the wild horſe is naturally as untractable as the zebra; for, it is probable, if he were early accuſtomed to obedience and a domeſtic life, he would become as docile as the horſe.

ERASED, in heraldry, expreſſes any thing that ſeems violently torn off from its proper place. It is uſed in contradiſtinction to couped, which ſignifies a thing clean cut off.

ERATO, from ερaω, *I love*, in mythology, the name of one of the nine muſes who preſided over love-poetry. To this muſe ſome have aſcribed the invention of the lyre and lute: and ſhe is repreſented with a garland of myrtles and roſes, holding a lyre in one hand, and a bow in the other, and at her ſide a Cupid with his torch.

EREBUS, Ερεϐος, from ערב, *night*, in mythology, a term denoting darkneſs. According to Heſiod, Erebus was the ſon of chaos and the night, and the father of the day. This was alſo the name of part of the inferi among the ancients: they had a peculiar expiation for thoſe who were detained in Erebus.

ERECT, in heraldry, any bearing placed perpendicular.

ERECTION, the act of raiſing or elevating a thing in a right line. The erecting a perpendicular on a line given, is a popular problem in geometry. The term erection is alſo uſed figuratively; as the erection of a marquiſate into a duchy; biſhoprics can only be erected by the king.

Erection is particularly uſed by medical writers, for the ſtate of the penis when ſwelled and diſtended by the action of the muſcles, called erectores. There is alſo an erection of the clitoris, which is performed by muſcles provided for that purpoſe, called alſo erectores. An alternate ſtate of erection and flaccidity in the penis, Dr. Drake obſerves, is of abſolute neceſſity; the firſt to the performance of its office, the ſecond for the ſecurity of the part. Without an erection it were impoſſible to emit and lodge the ſeed where it ought to be; and with a conſtant one, almoſt as impoſſible to ſecure the part from external injuries. To ſay nothing of the loſs of inſtigation, which muſt be a neceſſary conſequence of conſtant erection. The erection of the penis conſiſts in a diſtenſion of its corpora cavernoſa, by an extraordinary quantity of blood pent up therein. That the blood is the matter which diſtends the penis in erection, is evident from abundance of experiments; though the moſt convincing is that of firmly tying the penis of an animal (as has been frequently done to a dog) in coitu, wherein nothing has been found but blood to extend it. Hence, in the bodies of criminals, that hang long after death, the penis becomes erected; the blood in that poſition falling to the inferior parts, and ſtopping there. By blowing into the blood veſſels of the penis after death, the part becomes erected. This was firſt diſcovered by Mr. Cowper, upon viewing its veins, after he had diſtended them with wind; whence it plainly appeared, that the external trunks paſſed, ſome under its ſkin only, and ſome over the oſſa pubis; beſides, that a vaſt number of other veins on the dorſum penis unite and empty themſelves into one trunk, called vena penis, which paſſes immediately under a tranſverſe ligament of the oſſa pubis, which is compreſſed by the approximation of the dorſum penis to the ligament of the pubis.

ERECTORES *Clitoridis*, in anatomy, a pair of muſcles ariſing from the protuberances of the iſchium, and inſerted into the ſpongious body of the clitoris, which they ſerve to erect in coition.

ERECTORES *Penis*, in anatomy, a pair of muſcles, ariſing fleſhy from the protuberances of the iſchium below the beginning of the cavernous bodies of the yard, into whoſe thick membranes they are inſerted. Their uſe is to pull the yard upwards towards the os pubis, whereby the greateſt vein is compreſſed, and the refluent blood denied its paſſage under thoſe bones, which makes it ſwell. See Syſtem of Anatomy, Plate 10, *fig.* 1, Letters II.

ERIDANUS, in aſtronomy, a conſtellation of the ſouthern hemiſphere, in form of a river. See Syſtem of Astronomy, Sect. VIII.

ERINACEUS, or Hedge-hog, a genus of quadrupeds, belonging to the order of feræ, in the firſt claſs of the animal kingdom called Mammalia; the characters of which are theſe; they have two foreteeth in the upper jaw, at a conſiderable diſtance from one another, and two in the under jaw, leſs diſtant; and they have two recumbent dog-teeth, one on each ſide. There are three ſpecies, viz. 1. the europæus, or common hedge-hog, with round ears, and creſted noſtrils. It is about nine inches long; the upper part of the body is totally covered with ſharp prickles, and the under part is covered with hair. The hedge-hog, even when ſtanding on his legs, has a very ugly aſpect. His body is an oblong maſs, convex above, terminated on the fore-part by a very ſharp muzzle, and mounted on four ſhort legs, of which nothing appears but the feet, and the tail is not diſcernible. His ears are broad, round, and ſhort; and his eyes are ſmall and protuberant. The length of his body, from the point of the muzzle to the anus, is about nine inches. The hedge hog has a very uncommon method of defending himſelf from the attacks of other animals; being poſſeſſed of little ſtrength or agility, he does not attempt to fly from or aſſail his enemies; but erects his briſtles, and rolls himſelf up like a ball, expoſing no part of his body that is not furniſhed with ſharp weapons of defence; he will not unfold himſelf, unleſs thrown into water; the more he is frightened or harraſſed, the cloſer he ſhuts himſelf up: and frequently diſcharges his urine, which has a very fetid and lothſome ſmell. While in this ſtate, moſt dogs, inſtead of biting him, ſtand off and bark, not daring to ſieze him; or, if they attempt it once, their mouths are ſo prickled with his briſtles, that they cannot be prevailed upon to attempt it a ſecond time. Both the male and female are covered with briſtles from the head to the tail. Theſe briſtles are of great uſe in defending them from other animals; but muſt be very incovenient when they incline to copulate. This operation they cannot perform in the manner of other quadrupeds; but do it face to face, either ſtanding on end, or the female lying on her back. The females come in ſeaſon in the ſpring, and bring forth their young in the beginning of ſummer. They commonly bring forth three or four, and ſometimes five, at a time. The young ones are of a whitiſh colour, and only the points of the briſtles appear above the ſkin. It is impoſſible to tame them: the mother and her young have frequently been confined together, and furniſhed with plenty of proviſions; but, inſtead of nouriſhing them, ſhe uniformly devoured them one after another. Males and females have likewiſe been kept in one apartment, where they lived, but never copulated. Hedge-hogs feed upon fallen fruits, ſome roots, and inſects: they are very fond of fleſh-meat, whether raw or roaſted. They frequent woods, and live under the trunks of old trees, in the chinks of rocks, or under large ſtones. Naturaliſts allege, that they go into gardens, mount the trees, and come down with pears, apples, or plums, ſtuck upon their briſtles. But this is a miſtake: although kept in a garden, they never attempt to climb trees, or ſtick even fallen fruit upon their briſtles, but lay hold of their food with their mouth. They never come out of their holes in the day, but go about in queſt of food during the night. They eat but little, and can live very long without taking any nouriſhment. They do not lay up any ſtore of proviſions in harveſt: ſuch an inſtinct would be uſeleſs, as they ſleep all the winter. They lie under the undeſerved reproach of ſucking cattle and hurting their udders; but the ſmallneſs of their mouth renders that impoſſible. 2. The inauris, or white hedge-hog, has no external ears. It is a native of America. 3. The malaccenſis has hanging ears, and is a native of Aſia.

ERMIN, a ſpecies of the genus muſtella, of the order of Feræ, in the firſt claſs of the animal kingdom, called Mammalia.

ERMIN, or Ermine, in heraldry, this word alone ſignifies black ſpots on a white field, but if the word *plain* be uſed with it, it denotes nothing but white furs.

ERMINES, in heraldry, the reverſe of ermine, i. e. white ſpots on a black field.

EROSION, in medicine, the act of ſharp, acrid fluids, or humours, gnawing and tearing off parts from the fleſh, and other ſubſtances. Arſenic, and other poiſons, make eroſions in the inteſtines. See Corrosion.

EROWA, the name of a kind of nettle, which grows in the mountains at Otaheite in the South Sea, with which the inhabitants make fiſhing lines, which ſerve to hold the ſtrongeſt and moſt active fiſh, and are much ſtronger than our ſilk lines of twice the thickneſs.

ERRATA, a liſt uſually placed at the beginning or end of a book, containing the faults that have eſcaped in the impreſſion, and, ſometimes, even in the compoſition of the work.

ERRATIC, in general, ſometing that wanders, or is not regular; hence it is, the planets are called erratic ſtars in contradiſtinction to the fixed ſtars.

ERRHINA, Ερρινα, from εν, *in*, and ῥιν, *noſe*, in medicine, are remedies taken by the noſe to enliven the ſpirits, ſtop bleeding, &c.

ERROUR, Error, in philoſophy, a miſtake of our judgment, giving aſſent to that which is not true. Mr. Locke reduces the cauſes of error to theſe four; firſt, want of proofs; ſecondly, want of ability to uſe them; thirdly, want of will to uſe them; and, fourthly, wrong meaſures of probability. He obſerves upon the firſt of theſe cauſes of error, that the greateſt part of mankind want conveniencies and opportunities of making experiments and obſervations themſelves, or of collecting the teſtimony of others, being prevented by the neceſſity of their condition. Upon the ſecond of theſe cauſes, he obſerves, that there are many, who, from the ſtate of their condition, might beſtow time in collecting proofs, but yet are not able to carry a train of conſequences in their heads, nor weigh exactly the preponderancy of contrary proofs and teſtimonies, merely from the difference in mens underſtandings, apprehenſions, and reaſonings. Thirdly, he remarks, that though ſome have opportunities and leiſure enough, and want neither parts, learning, nor other helps, that they never come to the knowledge of ſeveral truths within their reach, either upon account of their attachment to pleaſure or buſineſs; and otherwiſe becauſe of their lazineſs or averſion to ſtudy. The fourth cauſe of error, viz. wrong meaſures of probability, he imputes, 1. To the practice of taking for principles, propoſitions that are not in themſelves certain and evident, but, on the contrary, doubtful and falſe. 2. To received hypotheſes. 3. Predominant paſſions or inclinations. And, 4. To authority, or the giving up our aſſent to the common received opinions either of our friends or party, neighbours or country.

The cauſes of error in philoſophy, or the reaſons why all former philoſophers have through ſo many ages erred, according to Lord Bacon, are theſe following. 1. Want of time ſuited to learning. 2. The little labour beſtowed upon natural philoſophy. 3. Few entirely addicted to natural philoſophy. 4. The end of the ſciences wrong fixed. 5. A wrong way choſen. 6. The neglect of experiments. 7. Regard to antiquity and authority. 8. Admiration of the works in uſe. 9. The artifice of teachers and writers on the ſciences. 10. Oſtentatious promiſes of the moderns. 11. Want of propoſing worthy taſks. 12. Superſtition and zeal being oppoſite to natural philoſophy, as thinking philophy dangerous, on account of the ſchool-theology; from the opinion that deep natural inquiries ſhould ſubvert religion. 13. Schools and academies proving unfavourable to philoſophy. 14. Want of rewards. And, 15. Deſpair, and the ſuppoſition of impoſition.

ERVUM, the lentil; a genus of the decandria order, belonging to the diadelphia claſs of plants. There are ſix ſpecies; of which the moſt remarkable is the lens, or common lentil. It is cultivated in many parts of England, either as fodder for cattle, or for the ſeeds which are frequently uſed in meagre ſoups. It is an annual plant, and riſes with weak ſtalks about 18 inches high, garniſhed with winged leaves compoſed of ſeveral pairs of narrow lobes, terminated by a claſper or tendril, which faſtens to any neighbouring plant, and is thereby ſupported. The ſeeds of this plant are moſt commonly ſown in the month of March, where the land is dry; but in moiſt ground, the beſt time is April. The uſual quantity of ſeed allowed for an acre of land is from one buſhel and a half to two buſhels. If theſe are ſown in drills, in the ſame manner as peaſe, they will ſucceed better than when ſown in broadcaſt: the drills ſhould be a foot and an half aſunder, to allow room for the Dutch hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the lentils and ſtarve them. There is another ſort of lentil alſo cultivated in this country under the name of French lentil. It is twice the ſize of the former, both in plant and ſeed; and is much better worth cultivation than the other.

ERUCA, denotes caterpillars of all kinds. See CATERPILLAR.

ERUDITION, denotes learning, or knowledge; and chiefly that of hiſtory and antiquity, of languages and of books, which is the reſult of hard ſtudy, and extenſive reading. Mr. Locke ſays, it is of more uſe to fill the head with reflections than with points of erudition. If the mind be not juſt and right, ignorance is better than erudition, which only produces confuſion and obſcurity.

ERUPTION, in general, a burſting forth, or excluſion of ſomething which was before covered, or concealed. In medicine, it denotes a ſudden and copious excretion of humours, as pus or blood, and any breaking out of puſtules or ſpots in various diſorders; as in the ſmall pox, meaſles, plague, fevers, &c.

The eruption of volcanos, or burning mountains, is frequently the effect and iſſue of earthquakes. See EARTHQUAKE, &c.

Dr. St. Clair, in the Philoſophical Tranſactions, gives an account of a conſtant eruption of fire on one ſide of one of the Appennines, between Bologna and Florence; a ſpot of ground three or four miles in diameter, he obſerves, inceſſantly ſends up a flame, riſing very high, without noiſe, ſmoke, or ſmell, though it gives a very great heat. In great rains it ſometimes intermits, but rekindles with greater vigour and heat. Within three or four yards of it, he adds, there grows corn. The flame he conjectures to ariſe from a vein of bitumen, or naphtha. There are three other ſuch fires on the ſame hills.

ERYNGIUM, SEA-HOLLY, or *Eryngo*; a genus of the digynia order, belonging to the pentandria claſs of plants. There are nine ſpecies; moſt of which are hardy herbaceous perennials, producing erect ſtalks from one to two or three feet high. They all flower moſtly in July, and the ſeeds ripen in September. They are propagated by ſeeds ſown in a bed or border, either in ſpring or autumn. The plants are to be removed the autumn after they come up, into thoſe places where they are deſigned to remain. The leaves of one of the ſpecies, (viz. the maritimum, which grows naturally on the ſea coaſts of England and Scotland) are ſweetiſh, with a light aromatic warmth and pungency. The roots are accounted aphrodiſiac, and are ordered to be kept candied in the ſhops. The young flowering ſhoots eaten like aſparagus are very grateful and nouriſhing.

ERYSIPELAS, Ερυσιϖελας, in medicine, a diſeaſe of the ſkin, called alſo *ſacer ignis*, and *St. Antony's fire*; and in many parts of Great Britain, the *roſe*. See Syſtem of MEDICINE.

ERYTHROIDES, in anatomy, the firſt of the proper membranes that encloſe the teſticles. It is interſperſed with fleſhy fibres, derived to it from the cremaſter muſcle, which makes it appear reddiſh. And hence its name from ερυθρος, *red*, and ειδος, *form*.

ESCALADE, or SCALADE, a furious attack of a wall or a rampart; carried on with ladders, to paſs the ditch, or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to ſecure the men.

ESCAPE, in law, an evaſion out of ſome lawful reſtraint, either by violence or ſtealth. Eſcapes are either voluntary, or negligent. Voluntary, as when one arreſts another for felony, or other crime, and afterwards lets him go, in which eſcape, the party that permits it, is, by law, to ſuffer puniſhment as if guilty of the fault committed by the perſon who eſcapes, be it felony, treaſon, or treſpaſs; after the original delinquent is actually found guilty or convicted. Negligent eſcape is, when one is arreſted, and afterwards eſcapes againſt his will that arreſted him; and is not purſued by freſh ſuit, and taken again, before the party purſuing hath loſt ſight of him. Keepers of priſons conniving at eſcapes ſhall forfeit 500l. and in civil caſes, the ſheriff is anſwerable for the debt.

ESCAPE *Warrant*, in law. If any perſon committed or charged in cuſtody in the king's bench or Fleet priſon in execution, or on meſne proceſs, &c. go at large: on oath thereof before a judge of the court where the action was brought, an eſcape warrant ſhall be granted, directed to all ſheriffs, &c. throughout England, to retake the priſoner, and commit him to goal when taken, there to remain until the debt is ſatisfied; and a perſon may be taken on a Sunday upon an eſcape warrant. Stat. 1 Anne, cap. 6.

ESCARTELE, in heraldry, quartered, or quarterly.

ESCHAR, in ſurgery, a hard cruſt, or ſcab, formed on the fleſh, by means of a hot iron, or a cauſtic medicine, or ſome ſharp corroſive humour within.

ESCHARA, the name of a ſpecies of corralline, &c. the characters of which are theſe: they are of a ſtony, or coral like hardneſs, and reſemble a woven cloth in their texture; and the microſcope ſhews us that they conſiſt of arrangements of very ſmall cells, whoſe ſurfaces appear much in that form. Linnæus makes it a ſpecies of millepora, a genus in the claſs of lithophytes. See Syſtem of VERMEOLOGY.

ESCHRAKITES, or ESRAKITES, a ſect of philoſophers, among the Mahometans, who adhere to the doctrines and opinions of Plato. The Eſchrakites, or Mahometan Platoniſts, place their higheſt good and happineſs in the contemplation of the divine majeſty. They are very careful in avoiding all vice; they preſerve an equal and eaſy temper, love muſic, and divert themſelves with compoſing little poems, or ſpiritual ſongs. The ſheics, or prieſts, and the chief among the preachers of the imperial moſques, are Eſchrakites.

ESCLAIRCISSEMENT, a French term, which we find retained in ſome Engliſh writers; it properly ſignifies the act, or effect, of clearing a thing, or rendering it more bright and tranſparent; being formed from the verb *eſclaircir*, *to clear*, &c. It is chiefly uſed in a figurative ſenſe, for an explanation of an obſcurity or difficulty. The eſclairciſſement of difficult paſſages in the Bible, is to be ſought for from ſimilar paſſages, or paſſages of the like kind occurring in other places.

ESCLATTE, in heraldry, is applied to a thing violently broken. Thus a bend, or rather partition, *eſclatte*, is repreſented torn, or broken off, like a ſhield ſhattered with the ſtroke of a battle-ax.

ESCORT, a French term, ſometimes uſed in Engliſh authors to denote a convoy, or company of armed men, attending ſome perſon or thing, in a journey or voyage, to defend or ſecure it from inſults.

ESCU, or ECU, the French crown, of ſixty ſols, or three livres. The eſcu was thus called, becauſe the eſcutcheon, or arms of France, which they call eſcu, was ſtruck thereon.

ESCULAPIUS, in mythology, the god of medicine. He was the ſon of Apollo, by the nymph Coronis, born at Epidauris, where he had a famous temple; in which his image, made of gold and ivory, was placed on a throne of the ſame materials; it was crowned with rays, had a knotty ſtick in one hand, and the other arm leaned upon a ſerpent, and a dog lay at his feet.

ESCULENTS, from *eſculentus*, *eatable*, a term uſually applied to vegetables which are fit for food, as artichokes, carrots, turneps, parſeheps, cabbages, cauliflowers, &c.

ESCURIAL, by the Spaniards writen ESCORIAL, a term that occurs pretty frequently in our gazettes, and news-papers, for a place of reſidence of the kings of Spain.

ESCUTCHEON, or SCUTCHEON, in heraldry, the field or coat, wherein the bearing, or arms, of any perſon, are repreſented. The word eſcutcheon is formed of the French *eſcuſſon*, and that from the Latin *ſcutum*, *ſhield*; which was the place arms were originally borne on, before ever they came on banners: and ſtill, wherever they are placed, it is on ſomething repreſenting the form of a ſhield. The eſcutcheon is of a ſquare figure, excepting the bottom part, which is uſually a little rounded, ending in a point in the middle. See Syſtem of HERALDRY.

ESOX, in ichthyology, a genus of fiſhes belonging to the order of abdominales. The body is elongated; the head is plainiſh above; the upper jaw is plain, and ſhorter than the under one, which is dotted; and the branchioſtege membrane has from ſeven to twelve rays.

There are nine ſpecies, of which the following are the moſt remarkable. The lucius, or pike, is common in moſt of the lakes of Europe; but the largeſt are thoſe taken in Lapland, which, according to Scheffer, are ſometimes eight feet long. They are taken there in great abundance, dried, and exported for ſale. The largeſt fiſh of this kind ſaid to be caught in England, weighed 35 pounds. All writers who treat of this ſpecies bring inſtances of its voraciouſneſs. It hath been known to choke itſelf by attempting to ſwallow one of its own ſpecies which proved too large a morſel. Yet its jaws are very looſely connected, and have on each ſide an additional bone like the jaw of a viper, which renders them capable of greater diſtenſion when it ſwallows its prey. It does not confine itſelf to feed on fiſh and frogs; it will devour the water-rat, and draw down the young ducks as they are ſwimming about. In the ſhallow water of the Lincolnſhire fens, they are often taken in a manner, we believe, peculiar to that country, and to the iſland of Ceylon. The fiſherman makes uſe of what is called a *crown-net*; which is no more than a hemiſpherical baſket, open at top and bottom. He ſtands at the end of one of the little fen-boats, and frequently puts his baſket down to the bottom of the water; then poking a ſtick into it, diſcovers whether he has any booty by the ſtriking of the fiſh: and vaſt numbers of pike are taken in this manner.

The longevity of this fiſh is very remarkable, if we may credit the accounts given of it. Rzaczynſki tells us of one that was 90 years old: but Geſner relates, that in the year 1497, a pike was taken near Hailbrun in Suabia, with a brazen ring affixed to it, on which were theſe words in Greek characters: "I am the fiſh which was firſt put into this lake by the governor of the univerſe, Frederick the Second, the 5th of October 1230:" So that the former muſt have been an infant to this Methuſalem of a fiſh. Pikes ſpawn in March or April, according to the coldneſs or warmneſs of the weather. When they are in high ſeaſon, their colours are very fine, being green, ſpotted with bright yellow; and the gills are of a moſt vivid and full red. When out of ſeaſon, the green changes to a grey, and the yellow ſpots turn pale.

The belone, or gar, ſometimes grows to the length of three feet or more. This fiſh, which is found in many places, is known by the name of the *ſea-needle*. It comes in ſhoals on our coaſts in the beginning of ſummer, and precedes the mackerel: it has a reſemblance to it in taſte: but the light green which ſtains the back bone of this fiſh gives many people a diſguſt to it.

The ſauruy, or ſaury. The tail is much forked: the back duſky: the belly bright and ſilvery. Great numbers of theſe fiſh were thrown aſhore on the ſands of Leith near Edinburgh, after a great ſtorm in November 1768. Rondeletius deſcribes this ſpecies among the fiſh of the Mediterranean: but ſpeaks of it as a rare kind.

ESPALIERS, in our gardening, are rows of trees, planted regularly round the outſide of a garden, or plantation, for the general ſecurity thereof, from the violence and injury of the winds; or elſe only round ſome part of a garden, for the particular ſecurity of a plantation of orange-trees, lemon-trees, myrtles, or other tender plants: or, laſtly, for the bounding of borders, walks, avenues, &c. See Treatiſe on Gardening.

ESPLANADE, in fortification, called alſo the glacis; the ſloping of the parapet of the covered-way towards the campaign.

ESPOUSALS, *ſponſalia*, in law, a contract or mutual promiſe between a man and a woman to marry each other. Marriage or matrimony is ſaid to be an *eſpouſal de preſenti*.

ESQUIMAUX, a people of North America, inhabiting all that vaſt tract of land known by the name of Labrador, or New Britain. They differ very conſiderably, both in aſpect and behaviour, from the other American nations; agreeing in moſt reſpects with the inhabitants of Weſt Greenland.

ESQUIRE, from the French *eſcu*, and the Latin *ſcutum*, in Greek σκυτος, which ſignify an hide, of which ſhields were anciently made, and afterwards covered; (for, in the time of the Anglo-Saxons, the ſhields had a covering of leather) was originally he, who, attending a knight in time of war, did carry his ſhield; whence he was called *eſcuier*, in French, and *ſcutifer*, or *armiger*, i.e. armour bearer, in Latin. Hotoman ſays, that thoſe whom the French call eſquires, were a military kind of vaſſals, having *jus ſcuti*, viz. liberty to bear a ſhield, and in it the enſigns of their family, in token of their gentility or dignity. But this addition hath not of long time had any relation to the office or employment of the perſon to whom it hath been attributed, as to carrying of arms, &c. but hath been merely a title of dignity, and next in degree to a knight. Officers of the king's courts, and of the king's houſhold, counſellors at law, juſtices of the peace, are only eſquires in reputation; and he who is a juſtice of peace has this title only during the time he is in commiſſion, and no longer, if he is not otherwiſe qualified to bear it. A ſheriff of a county being a ſuperior officer, bears the title of eſquire during his life; in reſpect of the great truſt he has in the commonwealth. The chief of ſome ancient families are eſquires by preſcription; and in late acts of parliament, many wealthy perſons commonly reputed to be ſuch, were ranked among the eſquires of this kingdom.

ESSAY, in matters of learning, is a peculiar kind of compoſition; whoſe character is to be free, eaſy, and natural; not tied to ſtrict order, or method, nor worked up, and finiſhed like a formal ſyſtem. The matter of an eſſay is ſuppoſed to conſiſt principally of ſudden and occaſional reflections, which are to be wrote much at the rate, and in the manner, a man thinks; ſometimes leaving the ſubject, and then returning again, as the thoughts happen to ariſe in the mind.

At leaſt, this has hitherto been the practice; and Montagne, who has acquired no ſmall reputation by this way of writing, ſeldom keeps many lines to the ſubject he propoſes; though it is our opinion, that lord Bacon, in many of his works, is a better pattern in the eſſay kind. Mr. Locke, however, and a few other authors, uſe eſſay in a ſeverer ſenſe: the eſſay on human underſtanding, every body knows, is a regular, artful, and laboured work; though perhaps ſo called to guard againſt too ſevere ſtrictures, by pleading the title.

Essay, in metallurgy, are chymical operations made in ſmall, to determine the quantity of metal or other matter which is contained in minerals, or to diſcover the value or purity of any maſs of gold or ſilver. See Assay.

ESSENCE, in metaphyſics, that which conſtitutes the particular nature of each genus or kind, and diſtinguiſhes it from all others; being nothing but that abſtract idea to which this name is affixed, ſo that every thing contained in it is eſſential to that particular kind. This Mr. Locke calls the nominal eſſence; in contradiſtinction to the real eſſence, or conſtitution of ſubſtances on which this nominal eſſence depends. Thus, the nominal eſſence of gold, is that complex idea the word gold ſtands for; let it be, for inſtance, a body, yellow, weighty, malleable, fuſible, and fixed: but its real eſſence is the conſtitution of its inſenſible parts, on which thoſe qualities and all its other properties depend, which is wholly unknown to us.

Essence, in medicine and chymiſtry, denotes the pureſt, moſt ſubtil, and balſamic part of a body, extracted from the reſt by means of fire. Of theſe there is a great variety, drawn from flowers, fruits, and the like, uſed on account of their agreeable ſmells, and taſtes, by the apothecaries, perfumers, &c. the principal are, eſſence of roſemary; of turpentine; of aniſe; of cloves; of cinnamon; and of citron. The eſſences commonly ſold by the perfumers, are only the diſtilled oils of balm, and of bitter almonds; to which they give the ſmell of certain flowers, or ſpices: as violets, jeſſamine, cinnamon, &c.

The eſſences to be drank, or mixed, with liquors, are of a more elaborate compoſition: the moſt uſual, and beſt, are prepared with ſpirit of wine, cloves, cinnamon, mace, long-pepper, and coriander. The whole, being put up in a very cloſe veſſel, is expoſed to the ſun for ſix weeks, or two months, during the day-time, and in the night ſet near the fire.

In winter they uſe the fire alone. This eſſence being exceedingly ſtrong, is frequently uſed only to give a ſtrength to other weaker liquors. After the ſame manner may the eſſences of ambergriſe, muſk, &c. be drawn. The eſſence of odoriferous flowers, to give a fine ſmell to liquors, is drawn by diſpoſing ſtrata, or lays, of the flowers, and of ſugar, alternately, in a proper veſſel, and leaving them to infuſe, in a cellar, for twenty-four hours; and after that, as long in the ſun; and, laſtly, ſtraining, or percolating, the whole through a ſieve, without ſqueezing the flowers.

ESSENES, or Essenians, in Jewiſh antiquity, one of the three ancient ſects among that people. They allowed a future ſtate, but denied a reſurrection from the dead. Their way of life was very ſingular: they did not marry; but adopted the children of others, whom they bred up in the inſtitutions of their ſect; they deſpiſed riches, and had all things in common, they never changed their cloaths till they were entirely worn out. When initiated, they were ſtrictly bound not to communicate the myſteries of their ſect to others; and if any of their members were found guilty of enormous crimes, they were expelled.

Pliny tells us, that they dwelt on the weſt ſide of the lake of Aſphaltites: and that they were a ſolitary kind of men, living without women or money, and feeding upon the fruit of the palm-tree; he adds, that they were conſtantly recruited by new comers, whom the ſurges of ill fortune had made weary of the world; in which manner the ſect was kept up for ſeveral hundreds of years, without any being born among them. The reaſon why we find no mention made of them in the New Teſtament, may be their recluſe and retired way of life, not leſs than their great ſimplicity and honeſty, whereby they lay open to no cenſure or reproof. For a particular account of this ſect, See Maynard's Tranſlation of Joſephus's Wars of the Jews, Book II. Chap. VII.

ESTATE, in law, ſignifies the title or intereſt that a perſon has in lands, tenements, or other effects; comprehending the whole in which a perſon hath any property, and will paſs the ſame. Eſtates are either real or perſonal: otherwiſe diſtinguiſhed into freeholds, which deſcend to heirs; or chattels, that go to executors or adminiſtrators. A fee-ſimple is the ampleſt eſtate our law admits of. Eſtates, in a political ſenſe, is uſed either to denote the dominions of ſome prince, or the general claſſes into which the people are divided. In Britain, the eſtates are the king, lords, and commons; or rather the lords and commons, who meet the king in parliament, for reforming abuſes, and enacting good and wholeſome laws.

ESTHER, a canonical book of the Old Teſtament; containing the hiſtory of a Jewiſh virgin, dwelling with her uncle Mordecai at Shuſhan, in the reign of Ahaſuerus, one of the kings of Perſia. The great beauty of this maid raiſed her to the throne of Perſia; whereby ſhe had an opportunity to ſave her countrymen, whoſe deſtruction was plotted by Haman, a favourite of that prince. The learned are not agreed who this Ahaſuerus was. Archbiſhop Uſher ſuppoſes him to be Darius Hyſtaſpes, and Artyſtona to be Eſther. Scaliger makes him the ſame with Xerxes, and his queen Hameſtris to be Eſther. Joſephus, on the contrary, poſitively aſſerts, that the Ahaſuerus of the ſcriptures, is the Artaxerxes Longimanus of profane ſtory; and the Septuagint, throughout the whole book of Eſther, tranſlate Ahaſuerus by Artaxerxes. Moſt people ſubſcribe to this laſt opinion; and, indeed the extraordinary kindneſs ſhewed by Artaxerxes to the Jews, can ſcarce be accounted for otherwiſe, than by ſuppoſing that they had ſo powerful an advocate as Eſther to ſolicit for them.

ETCHING, a method of engraving on copper, in which the lines or ſtrokes, inſtead of being cut with a tool or graver, are eaten in with aquafortis.

TREATISE ON THE ART OF ETCHING.

Etching is of a later invention, though not very modern, than engraving with the tool; of which it was at firſt only an imitation, that was practiſed by painters and other artiſts, who could much ſooner form their hand to, and attain a faculty of, working in this way, than with the graver. But being then nevertheleſs conſidered as a counterfeit kind of engraving, and therefore inferior to the other, it was cultivated in a very confined manner; the cloſeneſs of the reſemblance of the work to that performed by the tool, being made the teſt of its merit, and conſequently the principal object of aim in thoſe who purſued it. This ſervile confinement of the art of etching to the imitation of the original kind of engraving, was a great cauſe of retarding its advancement towards perfection, as many of the moſt able maſters cramped their talents with the obſervance of it; which may be ſeen in the inſtances of Sadelers, Swauneberg, Vilamene, and particularly Le Boſſe; who, in his treatiſe on engraving, has laid down as a principle, that the perfection of this kind conſiſts in the cloſe ſimilitude of the work with that done by the tool. This abſurd prepoſſeſſion has been ſince worn out; and the method of working with aquafortis has been ſo far improved, that, inſtead of being now deemed a ſpurious kind of engraving, it evidently appears the foundation of an excellence in many modern works, that could never have been produced without it; ſince, though the neatneſs and uniformity of the ſtrokes, which attend the uſe of the tool, is more advantageous with reſpect to portraits; yet the liberty and facility of the other manner give a much greater opportunity to exerciſe the force of genius and fancy in hiſtory-engraving; where the effect of the whole, and not the minute exactneſs in finiſhing all the parts, conſtitutes the principal value. There are two methods practiſed of engraving in this way; the one with a hard varniſh or ground, the other with a ſoft. The firſt was formerly much uſed, being better accommodated to the intention of imitating the engraving with the tool; as the firmneſs of the body of the varniſh gave more opportunity of retouching the lines, or enlarging them with the oval-pointed needles, called by the French *echoppes*, as was practiſed by Le Boſſe and others for that purpoſe. The latter has now almoſt wholly ſuperſeded the uſe of the other, by the free manner of working it admits of; which affords a power of expreſſion incompatible with the greater inflexibility of the hard varniſh, that confines the lines and ſtrokes to ſuch a regularity and ſameneſs, as gives a ſtiffneſs of manner and coldneſs of effect to the work.

The mixture of the uſe of the tool and aquafortis, which are now both employed in many caſes, has, however, given that perfection to engraving which it poſſeſſes at preſent. The truth and ſpirit of the out-line, that the method of working with aquafortis affords, and the variety of ſhades which the different kinds of black produce in this way, as well as other means of expreſſing the peculiar appearance and character of particular ſubjects, furniſh what was defective in the ſole uſe of the tool; while, on the other hand, the exactneſs and regularity of the lines, which are required for finiſhing many kinds of deſigns, are ſupplied by the graver; and by a judicious application of both, that complete finiſhing is obtained, which either of them alone muſt neceſſarily want.

The manner by which this art is performed, is the covering the ſurface of the plate with a proper varniſh or ground, as it is called, which is capable of reſiſting aquafortis; and then ſcoring or ſcratching away, by inſtruments reſembling needles, the parts of this varniſh or ground, in the places where the ſtrokes or hatches of the engraving are intended to be: then, the plate being covered with aquafortis, the parts that are laid naked and expoſed by removing the ground or varniſh, are corroded or eaten away by it; while the reſt, being ſecured and defended, remain untouched.

There are two methods of etching, as hath been already obſerved: the difference of which from each other conſiſts, as well in the difference of the varniſh or ground, as in that of the aquafortis, adapted to each kind: but the general method of performing them are alike in both. Theſe varniſhes or grounds are diſtinguiſhed by the names of hard and ſoft: for, in their conſiſtence, or the reſiſtance they give to the needles, lies their eſſential variation from each other. The hard varniſh, it is with good reaſon conjectured, was not the firſt in uſe: but ſoon took place of the other; and was, for ſome time, the moſt received in practice, on account of its admitting the work to be made more like that of the graver: the ſoft has, however, ſince, in its turn, prevailed to the excluſion of it in ſome degree, except in the caſe of particular ſubjects; but not ſo entirely as to take away the expedience of ſhewing how it is performed. The manner of etching with the ſoft varniſh is now, however, one of the important objects of the art of engraving; and it is at preſent in univerſal uſe, ſometimes alone, but more frequently intermixed with the work of the tool, and, in ſome caſes, with great advantage, even where the whole is intended to paſs for being performed by the graver.

Preparation of the ſoft Varniſh; according to Mr. Lawrence, an eminent Engliſh Engraver at Paris.

"Take of virgin's wax and aſphaltum, each two ounces; of black pitch and Burgundy pitch, each half an ounce. Melt the wax and pitch in a new earthen-ware glazed pot; and add to them, by degrees, the aſphaltum finely powdered. Let the whole boil, till ſuch time as that, taking a drop upon a plate, it will break when it is cold, on bending it double two or three times betwixt the fingers. The varuiſh being then enough boiled, muſt be taken off the fire; and, letting it cool a little, muſt be poured into warm water, that it may work the more eaſily with the hands, ſo as to be formed into balls; which muſt be rolled up, and put into a piece of taffety for uſe."

It muſt be obſerved, firſt, that the fire be not too violent, for fear of burning the ingredients; a ſlight ſimmering will be ſufficient: ſecondly, that while the aſphaltum is putting in, and even after it is mixed with them, the ingredients ſhould be ſtirred continually with the ſpatula: and thirdly, that the water, into which this compoſition is thrown, ſhould be nearly of the ſame degree of warmth with it, to prevent a kind of cracking that happens when the water is too cold. The varniſh ought always to be harder in ſummer than in the winter; and it will become ſo if it be ſuffered to boil longer, or if a greater proportion of the aſphaltum or brown reſin be uſed. The experiment above-mentioned, of the drop ſuffered to cool, will determine the degree of hardneſs or ſoftneſs that may be ſuitable to the ſeaſon when it is uſed.

Preparation of the hard Varniſh uſed by Callot, commonly called the Florence Varniſh.

Take four ounces of fat oil very clear, and made of good linſeed oil, like that uſed by painters: heat it in a clean pot of glazed earthen ware, and afterwards put to it four ounces of maſtich well powdered; and ſtir the mixture briſkly, till the whole be well melted; then paſs the whole maſs through a piece of fine linen, into a glaſs bottle with a long neck, that can be ſtopped very ſecurely; and keep it for the uſe that will be below explained. There are many other methods of making varniſh or ground, which we ſhall not enumerate; but only obſerve that thoſe who wiſh to procure ground, without the trouble of preparing it, may be ſupplied at ſeveral of the print or colour ſhops; where may alſo be had the oiled or tranſparent paper, neceſſary to trace the objects on the varniſh from the print or drawing.

Method of applying the ſoft Varniſh to the Plate, and of blackening it.

The plate being well poliſhed and burniſhed, as alſo cleanſed from all greaſineſs by chalk or Spaniſh white, fix a hand vice on the edge of the plate where no work is intended to be, to ſerve as a handle for managing it when warm: then put it upon a chafing diſh, in which there is a moderate fire; obſerving to hold it ſo, that it may not burn: keep the plate over the fire till it be ſo hot, that the varniſh being brought into contact with it, may melt: then cover the whole plate equally with a thin coat of the varniſh; and while the plate is warm, and the varniſh upon it in a fluid ſtate, beat every part of the varniſh gently with a ſmall ball or dauber made of cotton tied up in taffety; which operation ſmooths and diſtributes the varniſh equally over the plate.

When the plate is thus uniformly and thinly covered with the varniſh, it muſt be blackened by a piece of flambeau, or of a large candle, which affords a copious ſmoke; ſometimes two, or even four, ſuch candles are uſed together for the ſake of diſpatch, that the varniſh may not grow cold: which if it does during the operation, the plate muſt then be heated again, that it may be in a melted ſtate when that operation is performed: but great care muſt be taken not to burn it; which, when it happens, may be eaſily perceived by the varniſh appearing burnt and loſing its gloſs. The following expedient is made uſe of for the more commodious blackening the varniſh, being particularly neceſſary where the plates are large: fix a ſtrong hook in the roof of the room, through which paſs four pieces of cord of equal length, at the end of which are fixed four iron rings of about four inches diameter, for ſupporting the corners of the plate. The plate being thus ſuſpended in the air, with the varniſhed ſide downwards, may be blackened with great convenience: but this is not, however, abſolutely requiſite, except in the caſe of large plates that could not, without difficulty, be held up, unleſs this, or ſome other ſuch contrivance, were made uſe of.

It is proper to be very cautious in keeping the flambeau or candle at a due diſtance from the plate, leſt the wick touch the varniſh, which would both ſully and mark it. If it appear that the ſmoke has not penetrated the varniſh, the plate muſt be again placed for ſome little time over the chafing diſh; and it will be found, that, in proportion as the plate grows hot, the varniſh will melt and incorporate with the black which lay above it, in ſuch a manner that the whole will be equally pervaded by it.

Above all things, the greateſt caution ſhould be uſed in this operation, to keep all the time a moderate fire; and to move frequently the plate, and change the place of all the parts of it, that the varniſh may be alike melted every where, and kept from burning. Care muſt alſo be taken, that during this time, and even till the varniſh be entirely cold, no filth, ſparks, or duſt, fly on it; for they would then ſtick faſt, and ſpoil the work.

Method of applying the hard Varniſh.

This is preciſely the ſame as for the ſoft; being ſpread equally over the warm plate with the taffety-ball, and ſmoaked in the ſame manner: only after it is ſmoaked, it muſt be baked, or dried over a gentle fire of charcoal, till the ſmoke from the varniſh begins to decreaſe; taking care not to overheat the plate, which would both ſoften it and burn the varniſh.

The plate being thus prepared, and an exact drawing of the outlines of the deſign made upon thin paper, the other ſide of the paper muſt be well rubbed with chalk, or Spaniſh whitening, or, which is better, with red chalk ſcraped to a powder; and the looſe chalk is cleared off with a linen rag: then the ſtained ſide of the paper is laid upon the varniſh, fixing the corners to the plate with wax or wafers, to prevent its ſhuffling; and with a blunted needle, or pointer, the drawing is ſlightly traced, and communicates to the varniſh an exact outline of the deſign to be etched.

A variety of pointers is neceſſary for the work. Thoſe uſed for the broad large ſtrokes ought to be very blunt, exceeding round, and well poliſhed at the point; the ſole of a ſhoe anſwers very well for poliſhing the points. The fineſt ought to be as ſharp as a needle. If any ſcratches or falſe ſtrokes happen in the working, they are to be ſtopped up with a hair pencil dipped in Venetian varniſh, mixed with lamp black, by which means theſe places will be defended from the action of the aquafortis.

The next operation is that of eating or corroding the plate with aquafortis; in order to which, a border of ſoft wax (being a compoſition of bees wax melted and tempered with a little Venice turpentine and tallow), muſt be faſtened round the plate about an inch high, in the form of a little wall or rampart, to contain the aqua fortis. At one of the corners of this border a gutter is uſually made, which ſerves for pouring commodiouſly the aquafortis off the plate. The plate being thus bordered, take a due quantity of the refiners aquafortis; mix it with half its quantity of common water; and pour it gently on, till it riſe more than a finger's breadth above the ſurface of the plate: when, if all things have been rightly conducted, it will be ſeen that the aquafortis will ſoon exert its action in the ſtrokes, which have been ſtrongly touched; but thoſe more weakly engraved will appear at firſt clear, and of the colour of the copper. The menſtruum muſt therefore be ſuffered to continue on the plate till its effects become viſible on the more tender parts: then the aquafortis ſhould be poured off, the plate waſhed with clean water, and dried before the fire: then take a ſmall pencil dipped into the Venetian varniſh, and cover with it the lighter parts of the plate. This being done, the aquafortis muſt again be poured on, and ſuffered to continue a longer or ſhorter time, according to the ſtrength of the menſtruum, or the nature of the engraving; when it muſt be again poured off as before, and the plate immediately waſhed with water.

It may not be improper to obſerve, that, when the aquafortis is on the plate, a feather ſhould be uſed to cleanſe away the foulneſs of the verdigreaſe that gathers in the ſtrokes when the aquafortis operates on them, and to give it more room to exert its action; for by moving the aquafortis to and fro on the plate by the feather, and bruſhing away the black ſaline matter where it appears to be formed, the ſtrokes will be cleanſed, and the aquafortis exert its whole force equally on every part.

The plate being thus ſufficiently corroded by the aquafortis, and well waſhed with water, it muſt be warmed at the fire, and the border of wax removed; after which, it muſt be made hotter till the varniſh melt: then it muſt be well wiped with a linen cloth, and afterwards rubbed heartily with oil of olives; when it will be ready to be retouched and finiſhed by the graver. See the article ENGRAVING.

ETERNITY, an attribute of the Deity, expreſſing his infinite or endleſs duration. According to Mr. Locke, we come by an idea of eternity, by being able to repeat any part of time, as a year, as often as we will, without ever coming to an end.

ETHER. See ÆTHER.

ETHICS, the doctrine of manners, or the ſcience of moral philoſophy. The word is formed from ηθος, ηθη, *mores*, manners; by reaſon the ſcope or object thereof is to form the manners. See *Moral* PHILOSOPHY.

ETHMOIDAL, ETHMOIDALIS, in anatomy, a denomination given to one of the ſutures of the human cranium. The common ſutures are thoſe which ſeparate the bone of the cranium from thoſe of the cheeks, and are four; the tranſverſal, ethmoidal, ſphenoidal, and zygomatical. The ethmoidal takes its denomination from its turning round the os ethmoides.

ETHMOIDES, Εθμοειδης, in anatomy, a bone ſituate in the midddle of the baſis of the forehead or os frontis, and at the top of the root of the noſe. See Syſtem of ANATOMY. Part II. Sect. XIII.

ETIQUETTE, a French term, primarily denoting a ticket or title, affixed to a bag or bundle of papers, expreſſing its contents. It is alſo uſed when applied to the Spaniſh and ſome other courts, to ſignify a particular account of what is to be done daily in the king's houſhold, and in the chief ceremonies relating to it. It likewiſe denotes thoſe forms that regulate the decorum of conduct towards perſons of various ranks and ſtations.

ETYMOLOGY, that part of grammar which conſiders and explains the origin and derivation of words, in order to arrive at their firſt and primary ſignification, whence Quintilian calls it *originatio*. The word is formed of the Greek ετυμος, *verus*, true, and λεγω, *dico*, I ſpeak; whence λογια, *diſcourſe*, &c.; and thence Cicero calls the etymology, *notatio*, and *veriloquium*: though Quintilian chooſes rather to call it *orignatio*.

A judicious inquiry into etymologies, is thought by ſome of conſiderable uſe; becauſe nations, who value themſelves upon their antiquity, have always looked on the antiquity of their language as one of the beſt titles they could plead; and the etymologiſt, by ſeeking the true and original reaſon of the notions and ideas fixed to each word and expreſſion, may often furniſh an argument of antiquity, from the traces remaining thereof, compared with the ancient uſes. Add, that etymologies are neceſſary for the thorough underſtanding of a language. For, to explain a term preciſely, there ſeems a neceſſity of recurring to its firſt impoſition, in order to ſpeak juſtly and ſatisfactorily thereof. The force and extent of a word is generally better conceived when a perſon knows its origin and etymology. It is objected, however, that the art is arbitrary, and built altogether on conjectures and appearances; and the etymologiſts are charged with deriving their words from where they pleaſe. And indeed it is no eaſy matter to go back into the ancient Britiſh and Gauliſh ages, and to follow, as it were, by the track, the various imperceptible alterations a language has undergone from age to age, and as thoſe alterations have ſometimes been merely owing to caprice, it is eaſy to take a mere imagination or conjecture for a regular analogy: ſo that it is no wonder the public ſhould be prejudiced againſt a ſcience which ſeems to ſtand on ſo precarious a footing. It muſt certainly be owned, that etymologies are frequently ſo far fetched, that one can ſcarce ſee any reſemblance or correſpondence therein. Quintilian has ſhewn, that the ancient etymologiſts, notwithſtanding all their learning, fell into very ridiculous derivations. The etymologies of our Engliſh words have been derived from the Saxon, Welch, Walloon, Daniſh, Latin, Greek, &c. In this work the etymologies of terms are generally noted, where their obviouſneſs does not render it unneceſſary, or their doubtfulneſs or unimportance uſeleſs.

EVACUANTS, in medicine, remedies proper to expel or carry off any ill, peccant, or redundant humours in the human body, by the proper outlets or emunctories.

EVACUATION, in medicine, a diminution of the animal fluids, in order to a diſcharge of ſome morbid or redundant matters; or only for the ſake of thinning, attenuating, and thereby promoting motion and circulation. See Syſtem of MEDICINE.

EVACUATION is likewiſe uſed in the art of war, where, to evacuate a place is to make the garriſon quit or march out of it, in order for another power to take poſſeſſion of it, or to make room for another garriſon.

EVANGELISTS, the inſpired authors of the Goſpels. The word is derived from the Greek, ευαγγελιον, formed of ευ *bene, well*, and αγγελος, *angel, meſſenger*. The denomination evangeliſts was likewiſe given in the ancient church to ſuch as preached the Goſpel, without being attached to any particular church, being either commiſſioned by the apoſtles to inſtruct the nations, or of their own accord, abandoning every worldly attachment, conſecrated themſelves to the ſacred office of preaching the Goſpel. In this ſenſe ſome interpreters think it is that St. Philip, who was one of the ſeven deacons, is called the evangeliſt, in the twenty-firſt chaper of the acts of the apoſtles, ver. 8. Again, St. Paul writing to Timothy, Ep. ii. chap. iv. ver. 5. bids him do the work of an evangeliſt. The ſame apoſtle, Eph. iv. 11, ranks the evangeliſts after the apoſtles and prophets.

EVAPORATION, in natural philoſophy, is the diſſipation of the parts of any ſubſtance, either ſolid or fluid, into the air, in the form of ſmoke, or otherwiſe, in an inviſible manner, ſo that the ſubſtance evaporated then forms a fluid of equal ſubtilty and tranſparency with air itſelf. When any ſubſtance is diſſipated ſlowly and inſenſibly by ſimple expoſure to the atmoſphere, as water, camphor, &c. the evaporation is ſaid to be *ſpontaneous*.

TREATISE ON EVAPORATION.

Evaporation, in all caſes, is greatly promoted by heat. Many ſubſtances may be made to evaporate by means of a ſtrong fire, which otherwiſe appear abſolutely fixed; and there are but few which can reſiſt the violent action of the focus of a large burning mirror, without being in great part diſſipated.

Degrees of Heat requiſite to make different Fluids boil.

The degree of heat in which different bodies begin ſenſibly to evaporate is very different. When fluids of all kinds have been heated to a certain degree, their evaporation is attended with great inteſtine motion called *boiling*; and as then the diſſipation becomes much more ſenſible than before, this degree of heat is called their *evaporific point*; but improperly, for they begin ſenſibly to evaporate long before. The boiling point of all fluids is by no means the ſame; and the degree of heat which would cauſe the moſt fuſible metal to boil, is prodigiouſly greater than what would diſſipate the moſt fixed and ponderous fluid with the utmoſt rapidity. Vitriolic, and eſpecially nitrous ether, boil with a heat very little greater than that of our atmoſphere in ſummer. Spirit of wine requires Fahrenheit's thermometer to be raiſed 175 degrees above 0, before it boils; water requires 212 of the ſame degrees; oil of vitriol 550, oil of turpentine 560, quickſilver and linſeed oil 600, before they boil.

The quantity of any ſubſtance evaporated is found to depend ſo much on the degree of heat applied to it, that heat alone is generally reckoned to be the ſole cauſe of evaporation. Many perplexing circumſtances, however, occur, when we attempt to explain the manner in which a body, water for inſtance, naturally 800 times heavier than air, ſhould become ſo much ſpecifically lighter, as to be carried up by it to a very conſiderable height. One of the moſt generally received opinions concerning the formation of vapour is that adopted by Dr. Halley.

Dr. Halley's Theory of Evaporation.

He ſuppoſes that a bubble, compoſed of a particle of air incloſed by a thin film of water is rarefied by heat to ſuch a degree, that it becomes ſpecifically lighter than common air; in conſequence of which, ſuch particles, whatever be their number, muſt aſcend, and be ſuſpended in the air when they arrive at ſuch an height as to find the atmoſphere preciſely of the ſame ſpecific gravity with themſelves. But many objections may be made to ſuch a theory. For though a great quantity of air is diſperſed in water, it is not eaſy to account for the formation of a bubble diſtinct from the maſs of water; nor, though we could account for this, ought it to be taken for granted without ſufficient proof; and it remains to be explained by what means theſe bubbles would aſcend into the air: becauſe, by reaſon of their extreme ſmall ſize, the cold of the external air would almoſt inſtantly reduce the rarefied air-bubble to the ſame ſpecific gravity with itſelf. The bubble would then become ſpecifically heavier than the atmoſphere, and immediately fall down; ſo that vapour, inſtead of riſing to the height of two or three miles, could ſcarce riſe to the height of as many feet.

Lord Kaims's and Profeſſor Hamilton's Theory.

To avoid the difficulties to which the above-mentioned theory is liable, another hath been publiſhed by Lord Kaims and profeſſor Hamilton. They account for evaporation on the principle of elective attraction, and then ſolve the natural phenomena in the following manner. 1. "By an elective attraction between air and water, there is always a quantity of air in water and of water in air. 2. When water is ſaturated with air, it will take up no more; and in like manner, air ſaturated with water attracts no more. 3. This power of elective attraction is augmented by heat; for after air is ſaturated with water, or water with air, they will attract more by increaſing their heat. 4. The air with its moiſture being rarefied by heat, aſcends to a higher region, giving place to purer air not yet ſaturated, which accordingly attracts more moiſture, and water by that means is diffuſed through the air. 5. The groſſer particles of water, ſwimming in the air, being accumulated by wind, eſpecially contrary winds, become viſible clouds, and fall down in rain by the force of gravity overcoming the elective attraction. 6. Cold alſo contributes its part, by condenſing the watery particles, which fall down in ſnow when the cold is violent; and by theſe means a conſtant circulation of moiſture is carried on." This hypotheſis is alſo liable to be overthrown: for, according to it; evaporation ought not to take place *in vacuo* which is contrary to experience. The anſwer given by lord Kaims to this objection is a denial of the fact. Profeſſor Hamilton owns the diſſipation of water by heat *in vacuo*; but denies that this is really evaporation, which he maintains to be a true ſolution of water in air; and as a proof of this, he puts ſome water well purged of air under the exhauſted receiver of an air-pump, and found that it loſt only 2½ grains in the ſame time that an equal quantity expoſed to the air loſt 35 grains.

Mr. Watt's Experiment concerning the Evaporation of Water in vacuo.

That water can be converted into ſteam *in vacuo*, cannot be denied without the greateſt ſcepticiſm. It is even found much more eaſily diſſipated *in vacuo*, than when expoſed to the open air, and boils with much leſs heat; 92 or 95 degrees being ſufficient to make water boil *in vacuo*, whereas it requires 212° to make it boil when expoſed to the air. Concerning this, Dr. Black relates the following experiment.—Mr. Watt of Glaſgow, having formed a project of performing the evaporation of water *in vacuo*, with a view to convert it into ſteam with leſs expence of fuel, communicated his ſcheme to the doctor. The experiment was made with a ſmall ſtill reſembling the body of a retort, with a veſſel ſerving as a condenſer. The whole apparatus was cloſe, except a little hole at the extremity of the condenſing veſſel. Into this diſtilling veſſel a quantity of water was put; it was then exhauſted of air, by taking the condenſing veſſel, and holding it up, that the retort might be undermoſt. Being held over the fire in this poſition, the whole was ſoon filled with ſteam, which expelled the air: and upon ſtopping the little hole, a pretty perfect vacuum was formed in the retort and condenſing veſſel. The diſtilling veſſel being then ſet upon the fire, and the condenſing veſſel plunged in cold water, the water in the ſtill began to boil, as might be known by the noiſe, with a degree of heat very little greater than that of the human body, and the ſteam came over, and was condenſed in the refrigeratory; but Mr. Watt obſerved that the evaporation was not quicker *in vacuo*, than when air was admitted.

Profeſſor Hamilton's Experiments inconcluſive.

Thus we ſee that water may be converted into ſteam by the effect of heat alone, without the aſſiſtance of air; and thus the hypotheſis of Lord Kaims falls to the ground. Profeſſor Hamilton's experiment is evidently inconcluſive, becauſe it does not appear to have been fairly made. He put a certain quantity of water under an exhauſted receiver for 24 hours, and expoſed an equal quantity to the air in the ſame room; the firſt loſt 2½ grains, the latter 35. From this we can conclude nothing but that the quantity of fluid, whatever it is, which remains after the receiver of an air-pump is exhauſted, is capable of taking up 2½ grains of water. As no more of this fluid could be admitted to the water, than the preciſe quantity contained in the receiver, it is plain, that the other quantity of water which was expoſed to the open air of a room, ought to have been included within a receiver of the ſame ſize with the firſt, from which the air was not exhauſted: for in the manner wherein this experiment was conducted, an immenſe quantity of air had acceſs to one veſſel, and only as much as could be contained in the receiver of an air-pump, of the medium remaining after the air is exhauſted, had acceſs to the other; ſo that it would have been very abſurd to expect the ſame reſult in both caſes. Even circumſtanced as the experiment is, it makes directly againſt that hypotheſis which the profeſſor is deſirous of ſupporting: for, as the air-pump he made uſe of was capable of rarefying the air two and forty times, had the evaporation depended on the ſmall quantity of air which was left in the receiver, only the two and fortieth part ought to have been diſſipated of what would have been loſt had the water been placed under a receiver full of air. Inſtead of this, a like quantity of water expoſed to the air contained in a large room, loſt only 14 times as much. Had the vacuum of the receiver been as large as the room, it is impoſſible to ſay how much would have been loſt; and the only concluſion we can draw is, that the air, however neceſſary to the aſcent of vapour, is in reality prejudicial to its firſt formation.

Cold produced by Evaporation.

A very remarkable circumſtance concerning the evaporation of fluids is, that ſome degree of cold is always produced in conſequence of it; and by means of ſome of the more volatile ones, a great degree of cold is produced. If ſome vitriolic ether is put into a phial, ſet in a ſmall veſſel of water, and the whole placed under an air-pump, the ether boils violently as ſoon as the air is exhauſted, while the water is frozen by the cold produced in conſequence of its evaporation. This circumſtance hath been made uſe of as a proof that evaporation is not occaſioned by heat; and the ſenſible coldneſs of vapour has been thought a demonſtration that heat could by no means be concerned in its formation. Dr. Black, however, who treats particularly of the formation of vapour, hath accounted for this in a very ſatisfactory manner; and gives heat, in a certain degree, as the cauſe of evaporation in all caſes whatever.

Dr. Black's Account of ſenſible and latent Heat.

This gentleman is of opinion, that all fluid ſubſtances, beſides the heat contained in them capable of affecting our ſenſes or a thermometer, contain a certain quantity united to them in ſuch a manner as not to be diſcoverable by either of theſe methods; which, however, on certain occaſions, is apt to break forth, and ſhew its proper qualities as heat or fire. Theſe two different ſtates of this fluid, he diſtinguiſhes by the names of ſenſible and latent heat. A proof that heat exiſts in this latent ſtate, he gives from a mixture of ice and with water. He obſerves, that, when two equal maſſes of the ſame matter heated to different degrees, are mixed together, the heat of the mixture ought to be an arithmetical mean betwixt the two extremes. But, on pouring hot water upon ice, he found the caſe to be conſiderably different, and that a quantity of heat was entirely loſt; which he could account for in no other manner than by ſuppoſing, that it entered into the compoſition of the water, in ſuch a manner as to be in a latent ſtate, and the inviſible cauſe of the fluidity of that element.

Of the Formation of Vapour.

What happened in this caſe, to a mixture of ice and water, the doctor thinks, always happens on the converſion of water into ſteam or vapour by means of heat; a great quantity of the heat thrown into the fluid enters into it when in the ſtate of vapour, and forms a part of the fluid itſelf; in which ſtate it is not diſcoverable either by the thermometer or by the touch, but yet is ready to appear again in its proper form when the vapour is condenſed. The moſt concluſive experiments, mentioned by Dr. Black, as a proof of this theory, are, that hot water put under the exhauſted receiver of an air pump boils with great violence, and a part of it is ſuddenly diſperſed in vapour. During this time the water itſelf cools remarkably faſt, a part of the heat diſappears, and is neither to be found in the ſteam nor in the water. What then has become of it? The doctor concludes it ſtill exiſts in the ſteam, though in a latent ſtate, and not to be diſcovered by the common methods.

In this manner, likewiſe, he accounts for the above-mentioned experiment of the water freezing under an exhauſted receiver, in conſequence of the evaporation of the ether. This fluid being ſo extremely volatile that it went off in vapour when the temperature of the air was only 50°, abſorbed the ſenſible heat of the ſurrounding water, which entered into the compoſition of the ethereal vapour, and there remained in a latent ſtate. Certain it is, that, in this experiment, there was no perceptible increaſe of heat either in the ether or its vapour; the water indeed loſt heat conſiderably, but neither of theſe gained it.

The element of fire, however, is ſo exceedingly ſubtile, and ſo much eludes our moſt diligent ſearch, that we cannot conclude from its diſappearance in one place, that it has imperceptibly occupied another; the doctor, therefore, has yet a ſtronger argument in favour of his theory. He maintains, that, in the condenſation of ſteam by the refrigeratory of a common ſtill, as much heat is communicated to the water in the refrigeratory as would be ſufficient to heat the water which comes over to the heat of red hot iron, were it all to exiſt in it in the form of ſenſible heat. Nevertheleſs, the ſteam is at no time hotter than the boiling water which emits it. The exceſs of heat, therefore, muſt have exiſted in the ſteam in a latent ſtate, and become ſenſible during the condenſation.

The method of calculating this quantity of heat is very eaſy. For, ſuppoſing the refrigeratory to contain 100 pounds of water, and that one pound has been diſtilled: if the water in the refrigeratory has received 10 degrees of heat during the diſtillation, we know that the one pound diſtilled has parted with 1000. If, in paſſing through the worm of the refrigeratory, it has been reduced to the temperature of 50° of Fahrenheit's; having been at 212 when it entered the worm in form of ſteam, it has loſt only 162° of ſenſible heat; all the reſt of that heat which it communicated to the refrigeratory, amounting to above 800°, was contained in it while in the form of a ſteam, in ſuch a ſtate as not to be indicated by the thermometer.

By calculating in this manner, the doctor generally found, that the heat communicated by the ſteam was about 800 degrees; which would have been ſufficient to render a maſs of iron equal in bulk to the water which came over, red hot. In the experiment made by Mr. Watt, no leſs than 1000 degrees were communicated; though all the time the ſteam came over with a very gentle heat; but little ſuperior to what the hand could bear.

This experiment, no doubt, unanſwerably confirms the doctor's theory of heat. It is proper, however, to take notice, that a deception may very eaſily take place with ſuch as repeat the experiment in a careleſs manner. The upper part of the water in a refrigeratory grows very hot, while the under part is quite cold; and if a thermometer is plunged into it without ſtirring the water, a much greater degree of heat will be thought to be communicated than really there is. To avoid this miſtake, it is neceſſary to ſtir the water well about, and then meaſure its degree of heat. This theory of ſenſible and latent heat, ſo well eſtabliſhed, cannot but be looked upon as a valuable diſcovery in natural philoſophy; and will enable us to give a more ſatisfactory account of the formation of vapour when ſtrong degrees of heat are applied, as well as in the common heat of our atmoſphere, than any that hath hitherto been publiſhed. We ſhall begin with the converſion of any fluid, water, for inſtance, into vapour, when ſuch a degree of heat is applied as to make it boil.

How boiling Water is converted into Steam.

Here, the water has already received the utmoſt degree of heat which it is capable of containing. When a larger quantity continues ſtill to be thrown in, it muſt either paſs through the ſubſtance of the water and be diſſipated in the air, or combine with the aqueous particles in the form of ſteam. That the extreme agility of heat cauſes great part of it to paſs through the water and be loſt, cannot be denied; but it is alſo evident, that a very conſiderable part combines with the ſubſtance of the water, and is converted into vapour. The action of boiling conſiſts in the aſcent of a great number of bubbles from the bottom of the veſſel containing the water. Theſe, growing continually larger as they aſcend, break on the ſurface of the water, and are found to be compoſed of ſteam or vapour. As they continue till the evaporation of the very laſt drop of water, long after it has parted with all its air, this cannot be ſuppoſed to have any ſhare in their formation. Indeed, Dr. Boerhaave and others have proved, that there is no air contained in them; and both Dr. Black and Profeſſor Hamilton have ſhewn, that they are the very fluid which is diſſipated in the form of ſmoke. If, therefore, ſteam exiſts, and appears in its own proper form, when the air has no acceſs to it, which it has not till the bubble aſcends to the top and breaks in the air, it is impoſſible that air can have a ſhare in its formation; though by its ſuperior gravity it is the ſole cauſe of its aſcent.

If we are inclined, then, to call vapour a ſolution of water in any thing, it muſt be in heat, or fire; ſeeing, according to profeſſor Hamilton himſelf, it appears in the proper form of vapour before it has had any connection with the air.

Spontaneous Evaporation accounted for.

Upon the ſame principles we may eaſily account for the ſpontaneous or inſenſible evaporation of water when a degree of heat much leſs than that requiſite to cauſe it to boil is applied to it. From Dr. Black's experiments it appears, that a certain degree of heat is neceſſary to keep it in a fluid ſtate; and whatſoever degree is applied to it ſuperior to that abſolutely neceſſary to keep it fluid, appears to be but looſely connected with it, ſo that the water will very readily part with this ſuperfluous degree of heat to any colder body that comes in contact with it. Water in its fluid ſtate, then, we may conſider as a kind of compound, conſiſting of the pure element, and a certain quantity of heat ſo looſely combined with it as to affect the thermometer; but it is impoſſible that two ſubſtances having a tendency to mutual union can fail to be united in the cloſeſt manner of which they are capable when brought very near or in contact with each other. The water, therefore, having a conſtant tendency, to abſorb the ſenſible heat, and convert it into latent heat, muſt continue to do ſo more or leſs ſlowly according to the quantity contained in it. By this means there is a proportional quantity of vapour formed; for we muſt remember, that when heat and water are combined in the moſt intimate manner, they form a new ſubſtance totally different from water in its elementary ſtate. The particles of vapour thus formed, muſt neceſſarily aſcend to the ſurface of the water, and thence into the air, for the reaſons already mentioned; and thus there will be a conſtant exhalation from the ſurface of water, when the atmoſphere is of ſuch a temperature as to keep it fluid.

Why there is an Evaporation from Ice.

It now remains to account for the evaporation of water from ice; when the atmoſphere is of ſuch a nature as to deprive the water of great part of its ſenſible heat, and reduce it to a ſolid form. From a very curious experiment, Dr. Black hath ſhewn, that, in the act of freezing, the latent heat of the water is called forth, and becomes ſenſible. The ice, therefore, during the proceſs of congelation, is always a little warmer than the external air. In this caſe then, with regard to the external atmoſphere, it may be conſidered as ſimilar to water having a ſmall fire under it, ſo as to make it a degree or two warmer than the ſurrounding atmoſphere. The conſequence of this would be, that the freezing water would communicate part of its ſenſible heat to the air, and another part would intimately combine with the aqueous particles, and form a vapour which would be carried up into the atmoſphere. In like manner, the piece of ice, having a degree of ſenſible heat ſuperior to that of the air, will communicate to it part of that heat; while another part from its ſtrong tendency to unite with the water, will undoubtedly do ſo in its paſſage from the ice into the air, and carry off part of the aqueous particles in an imperceptible vapour.

Thus, according to Dr. Black's theory, whether the degree of heat contained in the atmoſphere is greater or leſs than that of water, there muſt be a continual evaporation of that fluid. There is only one caſe, upon his principles, where the evaporation muſt be little or nothing; and that is, when a piece of ice is in the action of melting. Here the water indeed receives heat from the atmoſphere: but as faſt as it is received, it paſſes from a ſenſible into a latent ſtate; and, till the water is ſaturated with latent heat, very little ſenſible heat can combine with the aqueous particles, ſo as to form them into ſteam. In this inſtance likewiſe, the Doctor's theory is verified by experience; for profeſſor Hamilton having incloſed a piece of ice, while thawing, in an exhauſted receiver, and likewiſe in one full of air, found that it loſt nothing by evaporation in 24 hours.

Evaporation promoted by Electricity.

From ſome experiments made by the Abbe Nollet, it appears, that evaporation is promoted by electricity. The conſequences of his experiments are as follow:

1. Electricity augments the natural evaporation of fluids; all that were tried, except mercury and oil, were found to ſuffer a diminution greater than what could be aſcribed to any other cauſe.

2. Electricity augments the evaporation of thoſe fluids the moſt, which are moſt ſubject to evaporate of themſelves; the volatile ſpirit of ſal ammoniac, ſuffering a greater loſs than ſpirit of wine or oil of turpentine; theſe two more than common water, and water more than vinegar or the ſolution of nitre.

3. The effects ſeemed always to be greater when the veſſels containing the fluids were non-electrics.

4. The increaſed evaporation was more conſiderable when the veſſel which contained the liquor was more open; but the effects did not increaſe in proportion to the apertures.

5. Electricity was alſo found to increaſe the evaporation of moiſture from ſolid bodies, and of conſequence to increaſe the inſenſible perſpiration of animals.

As the electric fluid is generally thought to be the ſame with the element of fire, it cannot be thought that this diſcovery can be any objection to Dr. Black's theory of the formation of vapour, but muſt rather tend to confirm it; as the phenomena of electricity preſent us with fire in a ſtate wherein it has no ſenſible heat, and which, agreeable to the Doctor's mode of expreſſion, may very properly be called its latent ſtate. The very great readineſs which this fluid ſhews to be converted into actual fire, ſo as even to fuſe metals, may alſo be reckoned a kind of demonſtration of the facility wherewith the ſenſible heat of any body may become latent, or the latent heat ſenſible.

Evaporation by means of heat, is one of the capital operations in chymiſtry; and where very great quantities of water are to be diſſipated, as in the making of common ſalt and green vitriol, it is a matter of no ſmall conſequence to contrive the evaporating veſſels in ſuch a manner as to diſſipate a large quantity of liquid in a ſhort time, and with little fuel. In the warmer countries, ſalt is made by the heat of the ſun alone; and even in the ſouthern parts of England, the heat of the ſolar rays is advantageouſly uſed to concentrate the brine.

Methods of evaporating great Quantities of Liquid in a ſhort Time.

This, however, can be but very ſeldom practiſed, and artificial evaporation is almoſt the only kind made uſe of in this country. The two great requiſites for promoting this, are, a ſufficient degree of heat to form a large quantity of ſteam, and a current of air to carry it off; for, though the vapour is always formed by the heat, yet if the air ſtagnates on the ſurface of the fluid, that part next the ſurface is heated to ſuch a degree, and ſo loaded with ſmoke, that the ſucceeding quantities of vapour are very conſiderably retarded in their aſcent. For this reaſon, evaporation is greatly promoted by having as large a ſurface of fluid expoſed to the air as poſſible, that the aſcent may be very quick; and where it is poſſible to procure a conſiderable blaſt of air along the ſurface of the veſſel containing the fluid, it will very much accelerate the diſſipation of it. On the ſame account, blowing air through the water while evaporating, increaſes the quantity of vapour to a ſurpriſing degree. It is obvious, however, that, by either of theſe methods, only time can be ſaved: for as the blaſt of cold air, whether directed along the ſurface of the fluid, or into its ſubſtance, will diminiſh the heat conſiderably; though the evaporation goes on very faſt, yet a proportional quantity of fuel will be required; and it is doubtful whether this method might in the end be attended with all the advantages promiſed by it at firſt view.

Diſtillation the beſt Method of evaporating.

On many accounts, diſtillation ſeems to be the moſt advantageous method of evaporating fluids, particularly as it both prevents any of the ſalts they may contain from being diſſipated, and ſeems to be the method by which the largeſt quantities of liquid can be evaporated in the ſhorteſt time, and with leaſt fuel. It is well known, that water in a ſtill, or any covered veſſel, can be kept boiling with much leſs heat than an equal quantity in an uncovered veſſel. As the quantity of ſteam is the ſame that ariſes from an equal ſurface of water where the heat is the ſame, whether the veſſel is covered or uncovered; it follows, that if proper vent is given to the ſteam in a covered veſſel, an equal quantity will be raiſed in a cloſe veſſel with leſs than in an open one and with an equal quantity of fuel, much moro might be evaporated, in the ſame time, in a cloſe than in an open veſſel. This ſeems confirmed by what Dr. Hales has advanced in his experiments concerning the freſhening of ſea water. He has found, that, by blowing air through the water contained in a ſtill, it is made to yield double thequantity which it otherwiſe would do. By this method, he obſerves, a ſtill which holds 20 gallons will yield, in 20 hours, 240 gallons of diſtilled water; and one which holds only five gallons may be made to diſtil 64, in the ſame time. Theſe are prodigious quantities; and which, we believe, could not be made to ariſe in an equal time from open veſſels of the ſame ſize, by any manœuvre whatever. Even deducting one half for the action of the bellows, the quantity is exceedingly great, being upwards of a gallon and an half per hour from a veſſel holding ony five gallons; and how difficult it would be to make this quantity ariſe from an open veſſel of ſuch a ſize, thoſe who are much concerned in evaporation will eaſily know.

EVAPORATION, in pharmacy, chymiſtry, &c. denotes an operation by which the more aqueous and volatile parts of fluids are ſpent, or driven away in ſteam, ſo as to leave the remaining part ſtronger, or of a higher conſiſtence than before. Evaporation is effected by ſetting liquor over a gentle heat, to carry off the moſt fluid and volatile parts, without leſſening the quantity of the other matters with which the liquor is impregnated.

EVATES, a branch or diviſion of the ancient Celtic philoſophers the Druids. Strabo diſtributes the philoſophers among the Britons and Gauls into three ſects; Βαρδοι, *Bards*; Ουατεις, *Evates*, and Δρυιδαι, *Druids*. He adds, that the Bardi were poets and muſicians; the Evates, prieſts and naturaliſts; and the Druids, moraliſts as well as naturaliſts. But Marcellinus, Voſſius, and Hornius, reduce them all to two ſects, viz. Bardi and Druids. Laſtly, Cæſar, lib. vi. comprehends them all under the name of Druids.

EUCHARIST, *Euchariſtia*, the ſacrament of the ſupper, or a participation of the body and blood of Chriſt, under the ſpecies or figures of bread and wine. The word in its original Greek, Ευχαριστια, literally imports *thankſgiving*, being formed of ευ, *bene, well*, and χαρις, *gratia, thanks*.

EUCHITES, or EUCHITÆ, a ſect of ancient heretics, who were firſt formed into a religious body, towards the end of the fourth century, though their doctrine and diſcipline ſubſiſted in Syria, Egypt, and other eaſtern countries before the birth of Chriſt; they were thus called becauſe they prayed without ceaſing, imagining that prayer alone was ſufficient to ſave them. Their great foundation were thoſe words of St. Paul, Epiſt. i. to the Theſſalonians, cap. v. ver. 17. *Pray without ceaſing*.

EUDIOMETER, in pneumatics, is an inſtrument lately invented, in conſequence of the experiments and diſcoveries of Dr. Prieſtley, for determining the ſalubrity of different kinds of air. The name is formed of ευδια, ſignifying the *good quality of air*, derived from ευ, *good*, and δια, denoting, in compoſition a *medium*, and μετρω, *I meaſure*. See Syſtem of PNEUMATICS.

EVER GREENS, a claſs of perennials, which continue their verdure, leaves, &c. all the year. Of theſe our gardeners reckon twelve, which are peculiarly fit for Engliſh air, viz. the alternus, arbutus, bay tree, box-tree, holly, juniper, lauruſtinus, phyllirea, pyracantha, or ever-green thorn, Italian green privet, and the yew-tree.

EVICTION, from *evinco, I overcome*, in law, ſignifies a recovery of lands or tenements by law.

EVIDENCE, that perception of truth which ariſes either from the teſtimony of the ſenſes, or from an induction of reaſon.

EVIDENCE, in law, ſignifies ſome proof, by teſtimony of men upon oath, or by writing or records. It is called evidence, becauſe thereby the point in iſſue in a cauſe to be tried, is to be made evident to the jury; for "probationes debent eſſe evidentes et perſpicuæ." The ſyſtem of evidence, as now eſtabliſhed in our courts of common law, is very full, comprehenſive, and refined; far different from, and ſuperior to, any thing known in the middle ages; as far ſuperior in that as in all other improvements and refinements in ſcience, arts, and manners. Vid. Blackſt. Comment. iii. 367, 375. iv. 350, 360.

The nature of evidence during the ages of ignorance was extremely imperfect, and the people were incapable of making any rational improvement. Thus it was the imperfection of human reaſon that cauſed the invention and introduction of the Ordeal, as an appeal to the ſupreme Being. As men are unable to comprehend the manner in which the Deity carries on the government of the univerſe, by equal, fixed, and general laws, they are apt to imagine, that, in every caſe which their paſſions or intereſt render important in their own eyes, the ſupreme Ruler of all ought viſibly to diſplay his power in vindicating innocence and puniſhing vice.

The evidences of the Chriſtian religion are diſtinguiſhed into two kinds, the direct and collateral; the direct evidences are external and internal; the external are miracles and propheſy; the internal evidence is deduced from its excellence, conſidered in reference to the main and principal end of Chriſtianity. Whatever does not either belong to its excellence conſidered in this light, or fall under the head of, miracles wrought on purpoſe to atteſt it, or of prophecies fulfilled, and yet affords a proof or any real preſumption of its truth and divinity, is a collateral evidence for it. All the collateral evidences of the truth of Chriſtianity are in one ſenſe internal evidences, becauſe they all ariſe from ſome particulars in the nature of this religion, from ſome circumſtances which have attended its reception or ſprung from it, or from ſome remarkable facts connected with it, and related in the Goſpel hiſtory. Of this kind is the argument deduced from its great efficacy at its firſt appearance, in baniſhing polytheiſm, idolatry, ſuperſtition, and the arts of magic; in ſoftening the rigour of deſpotiſm, introducing moderation into government, excluding many inconvenient civil laws once generally prevalent, giving riſe to others of a very happy tendency, refining the laws of war, humanizing the manners and improving the cuſtoms of nations, and reforming the temper and conduct of thoſe who embraced it. Another claſs of collateral arguments for the truth of the Chriſtian religion, ariſes from particulars in its nature or effects produced by it, or from facts in the goſpel hiſtory, which cannot be at all accounted for but on the ſuppoſition of a Divine original; or which are, at leaſt, moſt naturally explicable on that ſuppoſition. To this claſs may be referred thoſe preſumptive arguments deduced from the character of Jeſus, ſo exalted, and yet ſo uniformly ſupported; the nature of his laſt diſcourſes with his diſciples; the character of ſome of his apoſtles; that of Judas the traitor; the controverſies among Chriſtians in the apoſtolic age; and the method uſed by Chriſt and his apoſtles, of referring their claims to the impartial inquiries of men. Other collateral arguments have an affinity to the external evidences of Chriſtianity; ſuch are thoſe derived from the miraculous converſion of the apoſtle Paul, and his ſubſequent conduct: from the character of the man of ſin foretold by Paul; from the quick and extenſive propagation of the Goſpel; from the continuance and preſent ſtate of the nation of the Jews. Some of theſe arguments have an immediate relation to the proof of Chriſtianity from prophecies; others are related to the proof from miracles. Other arguments have an equal relation to the internal and external evidence of Chriſtianity; ſuch is that deduced from the manner in which Chriſt and his apoſtles propoſed the evidences of their miſſion, and the advantage they have gained in conſequence of the oppoſition and ſcrutiny of unbelievers. See on this ſubject Lord Lyttelton's Obſervations on the Converſion and Apoſtleſhip of St. Paul, Duchal's preſumptive Arguments for the truth of the Chriſtian Religion, Gerard's Diſſertation on the Genius and Evidences of Chriſtianity, and Fleetwood's Life of Chriſt.

EVIL, *malum*, in ethics, a privation or abſence of ſome proper or neceſſary good, or of ſome meaſure or degree thereof. Evil is either natural or moral; between which there is this relation, that moral evil produces natural.

Moral EVIL, is defined a deviation from right reaſon; a diſcernment of right from wrong, being given us as a guide of our actions; or it is the diſagreement between the actions of a moral agent and the rule of thoſe actions, whenceſoever it is derived and howſoever made known; and no action can be morally evil unleſs the agent be properly ſuch, intelligent, free, capable of diſtinguiſhing, chooſing, and acting for himſelf. This the philoſophers call *inhoneſtum*, and *turpe*, as ſtaining the image of God, and ſullying our original beauty, likewiſe *malum culpæ*.

Natural EVIL, is a want of ſomething neceſſary to the *bene eſſe*, or perfection of a thing, or to its anſwering all its purpoſes; ſuch are defects of the body, blindneſs, lameneſs, hunger, diſeaſes, death. This ſpecies is denominated *triſte, injucundum, noxium*, and *malum pœnæ*. Again, evil is either abſolute, as envy, impiety, &c.

or relative, as meat, which in itſelf being good, may be evil to a man on account of ſome diſeaſe; as wine to a feveriſh perſon, &c.

Evil, or *King's* **Evil**, in medicine, a diſeaſe by the phyſicians, called *ſtrumæ* and *ſcrophulæ*, conſiſting in ſcirrhous tumours, ariſing moſt commonly about the neck; but ſome alſo on the other glandulous parts, as the breaſt, arm-pits, groin, &c.

EULOGY, an encomium on any perſon, on account of ſome virtue or good quality.

EUNUCH, Ευνουχος, a term applied in the general to all who have not the faculty of generating, either through imbecility or frigidity; but more particularly ſuch as have been caſtrated, or have loſt ſome of the parts neceſſary for that purpoſe. In England, France, &c. eunuchs are never made but on occaſion of ſome diſeaſe which renders ſuch an operation neceſſary; but in Italy they make eunuchs for the ſake of preſerving the voice; and in the Eaſt they make eunuchs to be guards or attendants on their women. Great numbers of children, from one to three years of age, are yearly caſtrated in Italy to ſupply the operas and theatres, not only of Italy but other parts of Europe, with ſingers; though it is not one in three, that, after having loſt their virility, have a good voice for a recompence.

Tavernier aſſures us, that in the kingdom of Boutan in the Eaſt Indies, there are every year made twenty thouſand eunuchs, and ſold thence into other countries. The ſeraglios of the Eaſtern emperors are chiefly ſerved and guarded by eunuchs; and yet we have very good teſtimonies, that the rich eunuchs in Perſia and other countries keep ſeraglios for their own uſe. This is a puniſhment of crimes in ſome countries.

By an arret of the grand chamber of Paris in 1665, it is adjudged that an eunuch could not marry, not even with the conſent of the woman, and all the parties on both ſides. Claudian has a very ſevere ſatire againſt the eunuch Eutropius, who had been elected conſul of Rome. He repreſents him as an old woman, dreſſed up in the honours of the conſulate.

In the council of Nice thoſe were condemned, who, out of an indiſcrete zeal, and to guard themſelves from ſenſual pleaſures, ſhould make themſelves eunuchs. Such as thus mutilated their bodies were excluded from holy orders; witneſs Leontius, biſhop of Antioch, who was depoſed for having practiſed this cruelty on himſelf: and the biſhop of Alexandria excommunicated two monks who had followed his example, on pretence of ſecuring themſelves from the impetuous motions of concupiſcence. Several of the emperors made very ſevere prohibitions againſt the making of eunuchs, or people's caſtrating themſelves.

EVOLUTE, **Evoluta**, is the higher geometry, a curve firſt propoſed by Mr. Huygens, and ſince much ſtudied by the later mathematicians. The evolute is a curve, ſuppoſed to be evolved, or opened; and which, in opening, deſcribes other curves. See Syſtem of **Geometry**.

EVOLUTION, in the art of war, is a term applied to the diverſe figures, turns and motions, made by a body of ſoldiers, either in ranging themſelves in form of battle, or in changing their form: and this, whether in the way of exerciſe, or in the time of an actual engagement. It is by the evolutions that the form and poſture of a battalion, ſquadron, &c. are changed, either to make good the ground they are upon, or to poſſeſs themſelves of another, that they may attack the enemy or receive an onſet more advantageouſly. The military evolutions are converſions, countermarches or wheelings, doublings of rank and file, &c.

EUONYMUS, the ſpindle-tree; a genus of the monogynia order, belonging to the pentandria claſs of plants. There are two ſpecies. The europæus, diſcloſing their ſeeds in a beautiful manner in autumn; and the americanus, or evergreen ſpindle-tree. The berries of the firſt ſort vomit and purge very violently; and are fatal to ſheep. If powdered and ſprinkled upon hair, they deſtroy lice. If the wood is cut when the plant is in bloſſom, it is tough and not eaſily broken; and in that ſtate it is uſed by watchmakers for cleaning watches, and for making ſkewers and and tooth-pickers. Cows, goats, and ſheep, eat this plant; horſes refuſe it.

EUPATORIUM, hemp-agrimony; a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants. There are 13 ſpecies. One of which the cannabinum, or water hemp-agrimony, is a native of Britain. It grows by the banks of rivers and brooks, and has pale-red bloſſoms. The whole plant hath a very bitter taſte. A decoction of the roots operates as a violent emetic and cathartic; and is ſometimes taken by the lower claſs of people, to cure the jaundice, dropſy, &c. Dr. Boerhaave uſed an infuſion of this plant to foment ulcers and putrid ſores. Tournefort informs us, that the Turks cure the ſcurvy with it. An ounce of the juice or a dram of the extract is a doſe.

EUPHONY, ΕυΦωνια, in grammar, an eaſineſs, ſmoothneſs, and elegancy of pronunciation. The word is formed of ευ, *bene*, *well*, and Φωνη, *vox*, *voice*. Quintilian calls *euphonia*, *vocalitas*; Scaliger, *facilis pronunciatio*. Euphonia is properly a kind of figure, whereby we ſuppreſs a too harſh letter, or convert it into a ſmoother, contrary to the ordinary rules. There are examples enough in all languages.

EUPHORBIA, ſpurge; a genus of the trigynia order, belonging to the dodecandria claſs of plants. There are 62 ſpecies, ſix of which are natives of Great Britain. The juice of all the ſpecies is ſo acrid, that it corrodes and ulcerates the body wherever it is applied; ſo that phyſicians have ſeldom ventured to preſcribe it internally. Warts, or corns, anointed with the juice, preſently diſappear. A drop of it put into the hollow of an aching tooth, gives relief, like other corroſives, by deſtroying the nerve. Ipecacuanha is the root of one of the ſpecies.

EUROPA, in fabulous hiſtory, daughter of Agenor, king of Phœnicia; with whom Jupiter being in love, transformed himſelf into a bull, and ran away with her into this part of the world, which from her is called Europe.

EUROPE, one of the quarters of the world, bounded on the north by the Frozen Ocean, on the weſt by the Weſtern Ocean, on the ſouth by the Mediterranean, which ſeparates it from Africa, and by the Archipelago, which divides it in part from Aſia, as alſo by the Black Sea, then by the river Don, till it comes near the river Volga or Wolga.

EURYDICE, in mythology, the wife of Orpheus, who, flying from Ariſtæus that endeavoured to raviſh her, was ſlain by a ſerpent. Her huſband went down to the ſhades, and by the force of his muſic perſuaded Pluto and Proſerpine to give him leave to carry back his wife; which they granted, provided he did not look on her till he came to the light: but he, breaking the condition, was forced to leave her behind him.

EURYTHMY, Ευρυθμια, in architecture, painting, and ſculpture, a certain majeſty, elegance, and eaſineſs, appearing in the compoſition of divers members, or parts of a body, building, or painting, and reſulting from the fine proportions thereof. The word is Greek, and ſignifies literally a conſonance, or fine agreement, or, as we may call it, a harmony of all the parts, being compounded of ευ, *well*, and ρυθμος, *rhythmus*, *cadence*, or *agreement of numbers*, *ſounds*, or the like things. Vitruvius ranks eurythmia among the eſſential parts of architecture, he deſcribes it as conſiſting in the beauty of the conſtruction or aſſemblage of the ſeveral parts of the works, which renders its aſpect or whole appearance graceful; e. gr. when the height correſponds to the breadth, and the breadth to the length, &c.

From theſe three ideas or deſigns, viz. orthography, ſcenography, and profile, it is that eurythmy, *majeſtica*, and *venuſta ſpecies ædificii*, do reſult, which creates that agreeable harmony between the ſeveral dimenſions, ſo as nothing ſeems diſproportionate, too long for this, or too broad for that, but correſponds in a juſt and regular ſymmetry, and conſent of all the parts with the whole.

EUTERPE, of ευ, *well*, and τερπω, *I delight*, in mythology, one of the nine muſes, which preſided over wind inſtruments: ſhe is repreſented with a crown of flowers, playing on a double flute, with Cupid at her knees. To her the invention of tragedy is aſcribed.

EWE, the Engliſh name for a female ſheep.

EXACTION, in law, a wrong done by an officer, or one pretending to have authority: in taking a reward, or fee, for that in which the law allows not of any. The difference between exaction and extortion, conſiſts in this: that extortion is, where the officer takes more than his due; and exaction, where he wreſts a fee, or reward, where none is his due.

EXAGGERATION, in rhetoric, a figure whereby we enlarge or heighten things; making them appear more than they really are, whether as to goodneſs, badneſs, or other qualities. The word is formed of the Latin *exaggero*, *I exaggerate*; which is a compound of *ex* and *agger*, a *mound*, or *elevation of earth*.

Exaggeration, in painting, an affectation or method of repreſenting things different from nature, by introducing an extravagance of outline and colouring. Exaggerating differs from caricaturing; in that the latter perverts, or gives a turn to the features, &c. of a face, which they had not; whereas the former only heightens what they had. The latter is a kind of burleſque on the object, and is generally meant to ridicule: the former is uſually an exalting or enlivening of the beauties of the object, beyond what nature allows. The painter is obliged to have recourſe to an exaggeration of colours, both on account of the ſurface of his ground, the diſtance of his work, and of time, and the air, which diminiſh and weaken the force of the colours; but this exaggeration muſt be conducted in ſuch a manner, as not to put the objects out of their natural characters.

EXALTATION, *Elevation*, is chiefly uſed in a figurative ſenſe, for the raiſing or advancing a perſon to ſome eccleſiaſtical dignity: and particularly to the papacy. The term exaltation is, in ſome meaſure, appropriated the pope; and expreſſes his inauguration, coronation, taking poſſeſſion, and the beginning of his pontificate.

Exaltation, in phyſics, denotes the act, or operation, of elevating, purifying, ſubtilizing, or perfecting any natural body, its principles and parts; alſo the quality, or diſpoſition, which bodies acquire by ſuch operation.

EXAMEN, or **Examination**, an exact and careful ſearch or enquiry, in order to diſcover the truth or falſhood of a thing.

EXAMINERS, in chancery, are two officers, whoſe buſineſs is to examine, on oath, the witneſſes produced on both ſides, upon ſuch interrogatories as the parties to the ſuit exhibit for the purpoſe.

EXANTHEMA, formed of ἐξανθέω, *I flower*, in medicine, a preternatural eruption, or efflоreſcence, on the ſkin. Exanthemata are of two kinds; the one only a diſcolouring of the ſkin; ſuch as the meaſles, the purple ſpots in malignant fevers, &c. The other are little eminences, or papillæ, ſtanding out from the ſkin; ſuch are puſtules, ſmall pox, &c.

EXARTICULATION, a diſlocation of ſome of the jointed bones; or a breach of articulation.

EXCAVATION, formed of *ex* and *cavus*, *hollow*, or *cave*, a *pit*, &c. the act of hollowing, or digging a cavity, particularly in the ground.

EXCELLENCY, a quality, or title of honour, given to ambaſſadors, and other perſons, who are not qualified for that of highneſs, as not being princes; and yet are to be elevated above the other inferior dignities. In England, and France, the title is now peculiar to ambaſſadors; but it is very common in Germany and Italy. Thoſe to whom it was firſt appropriated were the princes of the blood, of the ſeveral royal houſes; but they quitted it for that of highneſs, upon ſeveral great lords aſſuming excellency. The Italian and French have improved on ſimple excellency; and made *excellentiſſimo*, and *excellentiſſime*, which have been beſtowed on certain popes, kings, &c.

EXCENTRIC, in the general ſenſe, departing or deviating from a centre. Excentric character, not adhering to any rule or mode, but totally governed by whim and caprice.

Excentric, in geometry, is applied where two circles, or ſpheres, though contained, in ſome meaſure, within each other, yet have not the ſame centre; and, conſequently, are not parallel; in oppoſition to concentric, where they are parallel, having one and the ſame common centre.

EXCENTRICITY, in aſtronomy, is the diſtance of the centre of the orbit of a planet from the centre of the ſun; that is, the diſtance between the centre of the ellipſis and the focus thereof. See Syſtem of Astronomy, Sect. VII.

EXCEPTION, ſomething reſerved, or ſet aſide, and not included in a rule. It is become proverbial, that there is no rule without an exception: intimating, that it is impoſſible to comprehend all the particular caſes under one and the ſame maxim. But it is dangerous following the exception preferably to the rule.

Exception, in law, is a ſtop or ſtay to an action. The term is uſed indifferently, both in the civil and common law; and in each, exceptions are divided into dilatory and peremptory. In law proceedings exception is a denial of a matter alledged in bar to the action; and in chancery it is that which is alledged againſt the ſufficiency of an anſwer, &c. Exception, in a general ſenſe, includes all the kinds of defence, or vindication, which a perſon, againſt whom a proceſs is brought, makes uſe of to prevent or retard its effect.

EXCESS is diſtinguiſhed into natural and moral: the firſt, is a part whereby one quantity is greater than another. Thus, we ſay, this lines is longer than that; but the exceſs is inconſiderable. The latter, is an intemperance, or going beyond the juſt bounds and meaſures preſcribed for any thing. Thus, we ſay, exceſs in wine, women, &c. is prejudicial to the health.

EXCHANGE, in a general ſenſe, a contract or agreement whereby one thing is given for another.

Exchange, in arithmetic, is the reduction of different coins, or any denomination of money, whether there be real coins anſwering to them, or no, from one to another; or the method of finding how many of one ſpecies, or denomination, are equal in value to a given number of another; in order to which it is neceſſary to know the value of the coins and monies of account of different countries, and their proportion to each other, according to the ſettled rate of exchange. The ſeveral operations in this caſe are only different applications of the rule of three. See Syſtem of Arithmetic, Article XVI.

Exchange, *Permutation*, in commerce, an agreement, whereby one thing is trucked or given for another. The firſt commerce carried on among men was by exchange; people furniſhing each other mutually with what things they wanted; but ſuch exchanges were clogged with two conſiderable difficulties. 1. On account of the unequal values of commodities; and, 2. Becauſe every body had not juſt what might accommodate the perſon with whom he would exchange. To remove theſe inconveniences, money was invented for a common medium; and inſtead of exchanging, buyiug and ſelling were introduced.

Yet, there are nations among whom the primitive way of exchange ſtill obtains; and even among the moſt civilized people, there are frequent occaſions, in which they have recourſe to this method. Such for inſtance, is the trade of ſeveral cities of the North, and Baltic Sea, where the French exchange their wines and brandies for woods, metals, hemps, and furs.

The commerce of bills of exchange is, itſelf, a mere trading by exchange: a truck of money for money. Exchange therefore, properly denotes the buſineſs, or trade of money, as carried on between one place and another, by means of bills of exchange, i. e. by giving money in one city, and receiving a bill to entitle the giver to receive the value in another city. See Bill of *Exchange*.

A regular bill of exchange is a mercantile contract, in which four perſons are concerned, viz. 1. The drawer, who receives the value: 2. His debtor, in a diſtant place, upon whom the bill is drawn, and who muſt accept and pay it: 3. The perſon who gives value for the bill, to whoſe order it is to be paid: and, 4. The perſon to whom it is ordered to be paid, creditor to the third.

By this operation, reciprocal debts, due in two diſtant parts, are paid by a ſort of transfer, or permutation of debtors and creditors.

A in London is creditor to B in Paris, value 100l. C again in London is debtor to D in Paris for a like ſum. By the operation of the bill of exchange, the London creditor is paid by the London debtor, and the Paris creditor is paid by the Paris debtor; conſequently, the two debts are paid, and no money is ſent from London to Paris, nor from Paris to London.

In this example, A is the drawer, B is the accepter, C is the purchaſer of the bill; and D receives the money. Two perſons here receive the money, A and D; and two pay the money, B and C; which is juſt what muſt be done when two debtors and two creditors clear accounts.

This is the plain principle of a bill of exchange; from which it appears, that reciprocal and equal debts only can be acquitted by them. When it therefore happens, that the reciprocal debts of London and Paris (to uſe the ſame example) are not equal, there ariſes a balance on one ſide. Suppoſe London to owe Paris a balance, value 100l. How can this be paid? Anſwer, It may either be done with or without the intervention of a bill.

Firſt with a bill, if an exchanger, finding a demand for a bill upon Paris for the value of 100l. when Paris owes no more to London, ſends 100l. to his correſpendent at Paris in coin, at the expence (ſuppoſe) of 1l. and then, having become creditor on Paris, he can give a bill for the value of 100l. upon his being repaid his expence, and paid for his riſk and trouble.

Or, ſecondly it may be paid without a bill, if the London debtor ſends the coin himſelf to his Paris creditor, without employing an exchanger. This laſt example ſhews of what little uſe bills are in the payment of balances. As far as the debts are equal, nothing can be more uſeful than bills of exchange; but the more they are uſeful in this eaſy way of buſineſs, the leſs profit there is to any perſon to make a trade of exchange, when he is not himſelf concerned either as debtor or creditor.

When merchants have occaſion to draw and remit bills for the liquidation of their own debts, active and paſſive, in diſtant parts, they meet upon 'Cchange; where, to purſue the former example, the creditors upon Paris, when they want money for bills, look out for thoſe who are debtors to it. The debtors to Paris again, when they want bills for money, ſeek for thoſe who are creditors upon it.

This market is conſtantly attended by brokers, who relieve the merchant of the trouble of ſearching for thoſe he wants. To the broker every one communicates his wants, ſo far as he finds it prudent; and by going about among all the merchants, the broker diſcovers the ſide upon which the greater demand lies, for money, or for bills.

He who is the demander in any bargain, has conſtantly the diſadvantage in dealing with him of whom he demands. This is no where ſo much the caſe as in exchange, and renders ſecrecy very eſſential to individuals among the merchants. If the London merchants want to pay their debts to Paris, when there is a balance againſt London, it is their intereſt to conceal their debts, and eſpecially the neceſſity they may be under to pay them; from the fear that thoſe who are creditors upon Paris would demand too high a price for the exchange over and above par.

On the other hand, thoſe who are creditors upon Paris, when Paris owes a balance to London, are as careful in concealing what is owing to them by Paris, from the fear that thoſe who are debtors to Paris, would avail themſelves of the competition among the Paris creditors, in order to obtain bills for their money, below the value of them, when at par. A creditor upon Paris, who is greatly preſſed for money at London, will willingly abaet ſomething of his debt, in order to get one who will give him money for it.

From the operation carried on among merchants upon 'Cchange, we may diſcover the conſequence of their ſeparate and jarring intereſts. They are conſtantly intereſted in the ſtate of the balance.

hoſe who are creditors on Paris, fear the balance due to Londoe; thoſe who are debtors to Paris, dread a balance due to Paris. The intereſt of the firſt is to diſſemble what they fear; that of the laſt, to exaggerate what they wiſh. The brokers are thoſe who determine the courſe of the day; and the moſt intelligent merchants are thoſe who diſpatch their buſineſs before the fact is known.

Merchants endeavour to ſimplify their buſineſs as much as poſſible; and commit to brokers many operations which require no peculiar talents to execute. This of exchange is of ſuch a nature, that it is hardly poſſible for a merchant to carry on the buſineſs of his bills, without their aſſiſtance, upon many occaſions. When merchants come upon 'Change, they are ſo full of fear and jealouſies, that they will not open themſelves to one another, leſt they ſhould diſcover what they want to conceal. The broker is a confidential man, in ſome degree, between parties, and brings them together.

Beſides the merchants who circulate among themſelves their reciprocal debts and credits ariſing from their importation and exportation of goods, there is another ſet of merchants who deal in exchange; which is the importation and exportation of money and bills.

But when balances come to be paid, exchange becomes intricate; and merchants are ſo much employed in particular branches of buſineſs, that they are obliged to leave the liquidation of their debts to a particular ſet of men, who make it turn out to the beſt advantage to themſelves.

The punctuality of acquitting theſe obligations is eſſential to commerce; and no ſooner is a merchant's accepted bill proteſted, than he is conſidered as a bankrupt. For this reaſon, the laws of moſt nations have given very extraordinary privileges to bills of exchange. The ſecurity of trade is eſſential to every ſociety; and were the claims of merchants to linger under the formalities of courts of law when liquidated by bills of exchange, faith, confidence, and punctuality, would quickly diſappear, and the great engine of commerce would be totally deſtroyed.

Exchange is not to be looked on as a loan, from which it differs; becauſe in the one, the riſque, or danger, lies on the perſon who borrows; and in the other, on him who lends. It likewiſe differs from intereſt, becauſe exchange is not paid in proportion to the time as intereſt is. Exchange is alſo uſed in divers places for the profit allowed for exchanging one ſort, or ſpecies of money for another. This is particularly called *ſmall exchange, natural exchange, pure exchange, &c.*

The coin of every ſtate has, beſides this, a relative value as it is compared with the money of other countries. This relative value is eſtabliſhed by the exchange, and greatly depends on its poſitive value. It is fixed by the current courſe of commerce, and by the general opinion and conſent of merchants, but never by the decrees of the prince, becauſe it is liable to inceſſant variations, depending on the accidental circumſtances of trade, the money tranſactions between nations, and the ſtate of public credit, &c. The ſeveral nations, in fixing the relative value of exchange, are chiefly guided by that which poſſeſſes the greateſt quantity of ſpecie. If ſhe has as much ſpecie as all others together, it is then moſt proper for the others to regulate their's by her ſtandard; and this regulation between all the others, will nearly agree with the regulation made with this principal nation. The relative abundance or ſcarcity of ſpecie in different countries, forms, what is called, the courſe of exchange; and this plenty or ſcarcity, on which the mutability of the courſe of exchange depends, is not real but relative: e. gr. when France has greater occaſion for funds in Holland than the Dutch of having funds in France, ſpecie is ſaid to be common in France, and ſcarce in Holland; and *vice verſa*. We may obſerve, in general, that there is much ſpecie in a place, when there is more ſpecie than paper; there is little, when there is more paper than ſpecie; and in order to judge of the ſcarcity or plenty of ſpecie, we muſt know, for example, that if there are more bills from Holland than there are from France, then ſpecie is ſcarce in France, and common in Holland; and therefore it becomes neceſſary that the exchange ſhould riſe, and the Dutch give more for ſpecie of the ſame value in France, than the French for that of an equivalent value in Holland. When money of the ſame ſtandard and weight in France yields money of the ſame ſtandard and weight in Holland, the exchange is then ſaid to be at par.

When the exchange is below par between one country and another, the former loſes as debtor and buyer, and gains as creditor and ſeller. Thus if France owes Holland a certain number of gros, the more of theſe there are in a crown, the more crowns ſhe has to pay; and as there muſt be the ſame number of gros to buy the ſame quantity of merchandiſe, while the exchange is low, every French crown is worth fewer gros. On the contrary, if France is creditor for a certain number of gros, the leſs of them there are in a crown, the more crowns ſhe will receive; and if France ſells her merchandiſe in Holland for a certain number of gros, the more crowns will ſhe receive, in proportion as each crown contains fewer of theſe gros. The ſame reaſoning will apply, *mutatis mutandis*, to the commercial intercourſe of other countries, and to any par of exchange. It is evident, that a merchant may ſend his ſtock into a foreign country, when the exchange is below par, without injuring his fortune; becauſe when it returns, he recovers what he had loſt; but a prince, who ſends only ſpecie into a foreign country, which can never return, is always a loſer. When merchants have great dealings in any country, the exchange there infallibly riſes, on account of their numerous engagements, buying great quantities of merchandiſe, and drawing on foreign countries to pay for them. The arbitration of exchanges is an article of great importance in the diſcuſſion of this ſubject; this is a kind of truck, which two bankers or merchants mutually make of their bills upon different parts, at a conditional price and courſe of exchange. When the courſe of exchange riſes above par, the places where it riſes may conclude for certain, that the balance of trade runs againſt them. The truth of this will appear if we ſuppoſe Britain to import from any foreign place, goods to the value of 100,000*l.* at par, and export only to the value of 80,000. In this caſe, bills on the ſaid foreign place, will be ſcarce in Britain, and conſequently will riſe in value; and after the 80,000 is paid, bills muſt be procured from other places, at a high rate, to pay the remainder, ſo that perhaps 120,000*l.* may be paid for bills to diſcharge a debt of 100,000*l.* Though the courſe of exchange be in a perpetual flux, and riſes or falls according to the circumſtances of trade, yet the exchanges of London, Holland, Hamburgh, and Venice, in a great meaſure, regulate thoſe of all other places in Europe.

In order to underſtand this branch of commerce, it is neceſſary to know how to reduce the ſterling money of England into the foreign monies of exchange and of account of all places through Europe, according to the direct courſes of exchange eſtabliſhed for theſe purpoſes, and *vice verſâ*; and alſo thoſe of other places, with which England has no direct eſtabliſhed courſes of exchange, but is under the neceſſity of making uſe of the intermediate changes of other places. The nature of the agios, and the manner of converting bank monies into current, and the reverſe, ſhould likewiſe be well underſtood. The method of reducing the foreign monies of Europe into thoſe of every other diſtant country, according to the direct or intermediate exchange, ſhould be thoroughly known; beſides, it is neceſſary to know the intrinſic value of foreign monies, according to the moſt accurate aſſays that have been made for that purpoſe; and alſo the general natural cauſes of the riſe and fall of the courſes of exchange between one nation or one city, and another; which depend on the balance of trade being either in favour of or againſt ſuch trading nation or city. By an accurate obſervation and compariſon of the courſes of exchange between various countries and cities, the merchant will have an opportunity of profit, which ſhould not eſcape his cognizance. He will find that they ſeldom ebb and flow in an exact equality of proportion, ſince the balance of trade differs between different nations. The greateſt profit may be made by ſeizing the opportunity of drawing and remitting to certain places preferably to others. Farther, when the exchange is lower than the ſpecie of a country, a profit may be made by ſending it abroad; when it is higher, there is a profit in cauſing it to return; but there is a caſe in which profit may be made, by ſending the ſpecie out of the kingdom, when the exchange is at par; that is, by ſending it into a foreign country, to be received; when it returns, an advantage may be made of it, whether it be circulated in the country, or paid for foreign bills. See farther on this ſubject, Poſt. Dict. Com. articles *Arbitration* and *Exchange*.

Exchange alſo denotes a public place, in moſt conſiderable cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other perſons concerned in commerce, meet, on certain days, and at certain times thereof; to confer, and treat together of matters relating to exchanges, remittances, payments, adventures, aſſurances, freightments, and other mercantile negociations, both by land and ſea. In Flanders, Holland, and ſeveral cities of France, theſe places are called *burſes*; at Paris and Lyons, *places de change*; and in the Hanſe towns, *colleges of merchants*. Theſe aſſemblies are held with ſo much exactneſs, and merchants and negociants are ſo indiſpenſably required to attend at them, that a perſon's abſence alone makes him be ſuſpected of a failure or bankruptcy. The moſt conſiderable exchanges in Europe, are that of Amſterdam; and that of London, called the Royal Exchange. For an account of the latter, ſee Royal Exchange.

Even in the time of the ancient Romans there were places for the merchants to meet, in moſt of the conſiderable cities of the empire. That ſaid by ſome to have been built at Rome in the year of the city 259, 493 years before our Saviour, under the conſulate of Appius Claudius and Publius Servilius, was called *collegium mercatorum*; whereof it is pretended there are ſtill ſome remains, called by the modern Romans *logia*, the *lodge*: and now, uſually, the *place of St. George*.

Exchange, in law, is a mutual grant of equal intereſt in lands or tenements, the one in exchange for the other; and in our common law it more particularly denotes the compenſation which the warrantor muſt make the warrantee, value for value, if the land warranted be recovered from the warrantee.

Exchange, *the King's*, is the place appointed by the king for exchange of plate, or bullion for the king's coin. Theſe places have formerly been numerous; but now there is only one, viz. that of the Tower of London, joined with the *Mint*.

Exchange *Brokers*, are perſons who make it their buſineſs to know the alteration of the courſe of exchange, to inform merchants how it goes, and to notify to thoſe who have money to receive or pay beyond ſea, who are proper perſons for executing their orders.

Exchangers, are thoſe who return money beyond ſea, by bills of exchange, &c. called anciently alſo *excambiators*, and ſince *remitters*.

EXCHEQUER, or ſimply *Chequer*, originally denotes a cheſsboard; or a frame divided into ſixty-four ſquares, of two colours, whereon to play at draughts, cheſs, &c.

Exchequer, is more particularly uſed for a chamber, or apartment, in Weſtminſter-hall, conſiſting of two parts; the court of exchequer and the lower exchequer. See Court *of Exchequer*.

Exchequer *Bills*, are a ſpecies of paper firſt eſtabliſhed by Mr. Montague, in 1696, to ſupply the want of circulating caſh, during the re-coinage at that period. They were then taken at the exchequer for all payment of the revenue, and, when re-iſſued, they were allowed 7*l.* 12*s.* *per cent.* intereſt. They have ſince been iſſued yearly; and the bank of England, ever ſince the year 1706, have been the contractors for their circulation, at a certain premium. The commiſſioners of the treaſury are empowered, by various ſtatutes, to borrow money, within a ſpecific ſum, limited by thoſe ſtatutes, by iſſuing exchequer bills on the credit of certain duties; which bills, by 12 Anne, cap. 11 & 12. Geo. I. cap. 11. bear an intereſt of 2*d.* a day per cent. payable to the bearers. Theſe bills are numbered arithmetically, and regiſtered accordingly, ſo that the principal ſums may be paid off in courſe, and the intereſt ſhall be payable every three months. The ſaid exchequer bills ſhall be current to all receivers and collectors of the cuſtoms, exciſe, or any revenue, and at the receipt of the exchequer; and as any of them are paid or lent into the exchequer, the officers there ſhall cauſe tallies to be levied and delivered to the payers or lenders, as if they had made ſuch payments or loans in ſpecie. If any exchequer bills be loſt, upon affidavit before a baron of the exchequer, and certificate from him, and ſecurity given to pay the ſame if found, duplicates are to be made out; and when bills are defaced, new ones ſhall be delivered. Forging of theſe bills, or of the endorſements on them, is felony.

Black Book of the EXCHEQUER, is a book under the keeping of the two chamberlains of the exchequer; ſaid to have been compoſed in 1175, by Gervais of Tilbury, nephew of king Henry II. and divided into ſeveral chapters. Herein is contained a deſcription of the court of England, as it then ſtood, its officers, their ranks, privileges, wages, perquiſites, power, and juriſdiction; and the revenues of the crown, both in money, grain, and cattle. Here we find, that for one ſhilling, as much bread might be bought as would ſerve a hundred men a whole day; that the price of a fat bullock was only twelve ſhillings, and a ſheep, four, &c.

EXCISE, (from the Belgic *accüſſe, tributum*, tribute,) an inland duty or impoſition, paid ſometimes upon the conſumption of the commodity, or frequently upon the wholeſale, which is the laſt ſtage before the conſumption. This is doubtleſs, impartially ſpeaking, the moſt œconomical way of taxing the ſubject; the charges of levying, collecting, and managing the exciſe-duties, being conſiderably leſs in proportion, than in other branches of the revenue. It alſo renders the commodity cheaper to the conſumer, than charging it with cuſtoms to the ſame amount would do; for the reaſon juſt now given, becauſe generally paid in a much later ſtage of it. But, at the ſame time, the rigour and arbitrary proceedings of exciſe-laws, ſeems hardly compatible with the temper of a free nation. For the frauds that might be committed in this branch of the revenue, unleſs a ſtrict watch is kept, make it neceſſary, wherever it is eſtabliſhed, to give the officers a power of entering and ſearching the houſes of ſuch as deal in exciſeable commodities, at any hour of the day, and, in many caſes, of the night likewiſe. And the proceedings, in caſe of tranſgreſſions, are ſo ſummary and ſudden, that a man may be convicted in two days time in the penalty of many thouſand pounds, by two commiſſioners or juſtices of the peace; to the total excluſion of the trial by jury, and diſregard of the common law. For which reaſon, though lord Clarendon tells us, that to his knowledge the earl of Bedford (who was made lord treaſurer by king Charles I. to oblige his parliament) intended to have ſet up the exciſe in England, yet it never made a part of that unfortunate prince's revenue; being firſt introduced, on the model of the Dutch prototype, by the parliament itſelf after its rupture with the crown. Yet ſuch was the opinion of its general unpopularity, that when in 1642 "aſperſions were caſt by malignant perſons upon the houſe of commons, that they intended to introduce exciſes, the houſe for its vindication therein did declare, that theſe rumours were falſe and ſcandalous, and that their authors ſhould be apprehended and brought to condign puniſhment." Its original eſtabliſhment was in 1643, and its progreſs was gradual; being at firſt laid upon thoſe perſons and commodities where it was ſuppoſed the hardſhip would be leaſt perceivable, viz. the makers and venders of beer, ale, cyder, and perry; and the royaliſts of Oxford ſoon followed the example of their brethren at Weſtminſter, by impoſing a ſimilar duty; both ſides proteſting, that it ſhould be continued no longer than to the end of the war, and then be utterly aboliſhed. But the parliament at Weſtminſter ſoon after impoſed it on fleſh, wine, tobacco, ſugar, and ſuch a multitude of other commodities, that it might be fairly denominated general; in purſuance of the plan laid down by Mr. Pymme (who ſeems to have been the father of the exciſe) in his letter to Sir John Hotham ſignifying, "that they had proceeded in the exciſe to many particulars, and intended to go on farther; but that it would be neceſſary to uſe the people to it by little and little." And afterwards, when the nation had been accuſtomed to it for a ſeries of years, the ſucceeding champions of liberty boldly and openly declared "the impoſt of exciſe to be the moſt eaſy and indifferent levy that could be laid upon the people:" and accordingly continued it during the whole uſurpation. Upon king Charles's return, it having then been long eſtabliſhed and its produce well known, ſome part of it was given to the crown, in 12 Car. II. by way of purchaſe for the feodal tenures and other oppreſſive parts of the hereditary revenue. But, from its firſt original to the preſent time, its very name has been odious to the people. It has, nevertheleſs, been impoſed on abundance of other commodities in the reigns of king William III. and every ſucceeding prince, to ſupport the enormous expences occaſioned by our wars on the continent. The articles of exciſe are now become ſo numerous that it would be tedious to recapitulate them; in fact they amount to a liſt, which no friend to his country would wiſh to ſee farther encreaſed.

The exciſe was formerly farmed out; but is now managed for the king by commiſſioners in both kingdoms, who receive the whole product of the exciſe, and pay it into the exchequer. Theſe commiſſioners are nine in number in England, and four in Scotland. The former have a ſalary of 1000*l.* a year, the latter 500*l.* They are obliged by oath to take no fee or reward but from the king himſelf; and from them there lies an appeal to five other commiſſioners called commiſſioners of appeals. Complaints made at the chief office of exciſe are to be heard by three or more commmiſſioners; but two juſtices of the peace have the power to determine in ſeizures out of the limits of the exciſe-office in London See further, Table to the quarto edition of the Statutes at Large; alſo an account of the method of charging the duties of exciſe, &c. at the end of Gilb. Exch. edit. 1758, p. 293.

EXCISION, in ſurgery, the cutting out, or cutting off any part of the body.

EXCLAMATION, in rhetoric, a figure, wherein, by raiſing the voice, and uſing an interjection either expreſly or underſtood, we teſtify an uncommon warmth, and paſſion of mind; and expreſs the magnitude of the thing, or the importance of the occaſion. Such is, O heavens! O earth! &c. ſuch alſo is that of Cicero againſt Cataline: O times! O manners! this the ſenate knows, the conſul ſees—and yet he lives! Lives, ſaid I? nay, and comes into the ſenate! In Engliſh, the interjections O! or oh! alas! or good God! are generally adjoined in an exclamation.

EXCLUSION, the act whereby a perſon or thing is excluded, i. e. ſhut out, or ſet aſide. A crown imports an excluſion from the papacy: he appointed a ſtranger his heir, in excluſion of his own relations. Great efforts were made towards the cloſe of the reign of king Charles II. to procure a bill of excluſion, for ſetting aſide the Duke of York, the king's brother, on account of his being a papiſt.

EXCLUSIVE, is ſometimes uſed adjectively, for the force, or power, of excluding: as, a patent carries with it an excluſive privilege. Sometimes it is alſo uſed adverbially: as, he ſent him all the gazettes, from N° 195, to N° 300, excluſive; i. e. all between thoſe two numbers, which themſelves were excepted.

EXCOMMUNICATION, an anathema, or eccleſiaſtical cenſure, and puniſhment; whereby a heretic is cut off from the ſociety of the faithful, or an obſtinate ſinner from the communion of the church, and the participation of the ſacraments. This cenſure of excommunication was originally inſtituted for preſerving the purity of the church; but ambitious eccleſiaſtics converted it by degrees into an engine for promoting their own power, and inflicted it on the moſt frivolous occaſions.

The power of excommunication properly belongs to the biſhop; but he may delegate it to any prieſt, with the chancellor. Excommunication is either major or minor, i. e. greater or leſs; the firſt, which is that underſtood when we ſay, ſimply, excommunication, ſeparates, or cuts off, the delinquent from all communion and fellowſhip with other Chriſtians; diſables him from defending his rights, bringing an action at law, being a witneſs, &c. The ſecond, or leſſer, only excludes from the communion of the Lord's ſupper.

In Spain, to this day, a perſon who is not abſolved from his excommunication in a year's time, is deemed a heretic. But, afterwards, the occaſions of excommunications growing more frequent, they began to uſe it with leſs circumſpection and reſervedneſs. In the ninth century, the eccleſiaſtics were continually making uſe of this ſpiritual weapon, to repel any violences, or affronts, offered them; and time and familiarity rendering offenders more and more obdurate, they proceeded, by degrees, to rigours unknown to antiquity, as the excommunicating of whole families, or provinces; prohibiting the exerciſe of all religion therein; and even accompanying the excommunication with horrible ceremonies, and direful imprecations.

In the tenth and eleventh centuries, the ſeverity againſt the excommunicated was carried to its higheſt pitch: no-body might come near them, not even their own wives, children, or ſervants; they forfeited all their natural and legal rights and privileges, and were excluded from all kinds of offices. Thus was an excommunicated king reduced to the condition of a private man. By thus ſtretching the power of the church to extravagance, they rendered it contemptible. Gregory VII. tempered it a little; exempting the wives and children of excommunicated perſons from incurring excommunication, by holding converſation with their huſbands and parents.

To render the excommunicated ſtill more odious, the prieſt was obliged to ſtop, and break off divine ſervice, if an excommunicated perſon entered the church; nothing of which averſion is any were diſcovered in the practice of the primitive church. At preſent we have but little of the terror or reſpect of our forefathers for excommunication; and it is even judged, and proclaimed, an abuſe, whenever impertinently employed.

The form of excommunication in the Romiſh church, as related by Feverct, is to take lighted torches, throw them on the ground with curſes and anathemas, and trample them out underfoot to the ringing of the bells. We have now none of this folly; the ſentence is gravely read, and the perſon remains excommunicated without farther ceremony. See the form of excommunication of the Engliſh church in Concilia M. Brit. & Hib. vol. iv. p. 663, &c.

The power of excommunicating was lodged in the whole church in general; that is, the biſhops and prieſts had the adminiſtration thereof, by and with the conſent of the people; which was practiſed even in St. Cyprian's time. But afterwards they ceaſed to conſult the people about the matter: the biſhop and clergy arrogated the whole power to themſelves. Recourſe, however, might ſtill be had to a ſynod of the province, to judge of the validity of an excommunication.

EXCOMMUNICATION was alſo practiſed among the Jews, who uſed to expel from their ſynagogue ſuch as had committed any grievous crime. See the Goſpel according to St. John ix. 22. xii. 42. xvi. 2. The Eſſeni, when excommunicated, durſt not ſo much as receive food at any perſons hands, for fear of violating their oath, but contented themſelves to live on herbs; inſomuch that they frequently periſhed, and died for want. See Maynard's Tranſlation of Joſephus—Wars of the Jews—Book 2. Chap. 7.

EXCOMMUNICATION, or a being ſecluded, or cut off from a participation in the myſteries of religion, was alſo in uſe under paganiſm. Such as were thus excommunicated were forbidden to aſſiſt or attend at the ſacrifices, or to enter within the temples; and were afterwards delivered over to the demons and furies of hell, with certain imprecations; which was called among the Romans, *diris devovere*. The Druids among the ancient Britons and Gauls, likewiſe, made uſe of excommunication againſt rebels; and interdicted the communion of their myſteries to ſuch as refuſed to acquieſce in their deciſions.

EXCORIATION, in medicine and ſurgery, the galling or rubbing off of the cuticle; eſpecially of the parts between the thighs, or about the anus. In adults, it is occaſioned by riding, much walking, or other vehement exerciſe, and may be cured by vulnerary applications. In children, there is often an excoriation of the parts near the pudenda, chiefly of the groin and ſcrotum, but likewiſe in the wrinkles of the neck, under the arms, and in other places, proceeding from the acrimony of the urine and ſweat, and occaſioning itching pains, crying, watching, and reſtleſſneſs. We alſo ſay, an excoriation in the throat, &c. when the membrane that covers it, or lines it, is torn by the acrimony of a humour, a medicine, or the like; which is ordinarily the caſe in what we call a ſore throat.

EXCORTICATION, the act of ſtripping off the cortex, or bark, from any thing; called alſo Decortication.

EXCREMENT, that which is evacuated, or excreted, out of the body of an animal, after digeſtion; being what in other reſpects is ſuperfluous and prejudicial thereto.

Excrement is all that matter taken in by way of food, which cannot be aſſimilated; and which, of conſequence, not growing or adhering to the body, wanders about through the laxer, and more patent parts thereof, till it be ejected. The urine and fæces, or fæcal matter, are the great excrements, expelled from the bladder, and the inteſtines, by ſtool, &c. The matter of inſenſible perſpiration is alſo an excrement, and a more conſiderable one than either of the others. Among excrements are likewiſe ordinarily ranked ſeveral humours and matters, ſeparated from the blood by the ſeveral ſtrainers, or emunctories of the body, though far from being uſeleſs, but ſerving valuable purpoſes of the animal œconomy. Such are the cerumen, or ear-wax; the mucus of the noſe: lachrymæ, or tears; ſaliva, bile, lympha, menſes, lochia, &c.

Unleſs the excretions are regular, health cannot be maintained; and therefore if they are too plentiful, defective, or ſuppreſſed, they will occaſion various diſorders. Hence if a perſon be coſtive, it is generally the forerunner of ſome diſeaſe. As a man generally takes more aliment than is neceſſary to generate blood and ſerum, and common excretions are not ſufficient to carry off ſuperfluous humours, extraordinary ones ſometimes happen at ſtated times; as the piles, hæmorrhages, &c.

EXCREMENT is alſo attributed, by way of analogy, to plants. Thus gums, diverſe juices, balms, &c. iſſuing ſpontaneouſly from their reſpective trees, are ſometimes called excrements.

EXCRESENCE, in ſurgery, denotes ſuperfluous, or luxurious fleſh, or other matter, growing on certain parts of the bodies of animals, contrary to, or beyond the ordinary ſtructure, and diſpoſition of nature. The word is formed of the Latin *ex*, and *creſco, I grow*; q. d. ſomething that grows from, or out of another. Such are wens, warts, ficuſes, polypuſes, &c. Natural, or cuſtomary excreſences, as thoſe of bones, &c. are called by phyſicians apophyſes.

EXCRETION, formed of *excernere, to ſeparate*, in medicine, the act of expelling or ejecting out of the body ſome humour that is uſeleſs, or even hurtful thereto. Moſt criſes are effected by excretion; as fluxes of blood and urine, ſweat, vomitings, looſeneſſes, &c.

EXCRETORY, in anatomy, is applied to certain little ducts, or veſſels, in the fabric of the glands. Excretory ducts are tubes through which the humours ſeparated in the ſeveral glands, are emitted, or diſcharged out of the gland, into ſome convenient receptacle, or emunctory. A capillary artery, to which a capillary vein is joined, with an excretory duct, convolved, or wound together, make up the body of the glands, the organs of ſecretion. The excretory ducts, ſpring from the extremities of the arteries and veins, and carry off a liquor ſeparated from the blood. The lymphatic glands have either lymphæducts for their excretory ducts, or lacteal veſſels, as in the meſentery. See Syſtem of ANATOMY, Part I. Sect. VI.

EXECRATION, *Execratio*, among the ancients, a kind of puniſhment, conſiſting of direful curſes and marks of infamy. Livy relates an inſtance of it, which was uſed againſt Philip, king of Macedon, by the Athenians. A general aſſembly of the people being called, they made a decree, that all the ſtatues and images of that king, and of all his anceſtors, both of the male and female ſex, ſhould be demoliſhed, and their very names raſed; that all the feſtivals, ſacred rites, prieſts, and whatever elſe had been inſtituted in honour of him, ſhould be profaned; that the very places where there had been any monument or inſcription to his honour, ſhould be deteſtable, and that nothing ſhould be ſet up, or dedicated in them, which could be done in clean places; and, laſtly, that the public prieſts, as often as they prayed for the Athenian people, allies, armies, and fleets, ſhould as many times deteſt and execrate Philip, his children, kingdom, land and ſea forces, and the whole race and name of the Macedonians.

EXECUTION, the act of executing, i. e. of accompliſhing, finiſhing, or atchieving any thing, to be done. We ſay, the execution of a teſtament; of a law; of a treaty; of a building, or the like.

EXECUTION, in common law, ſignifies the laſt performance of an act; as of a writ, a judgment, or the like.

EXECUTION *of a Judgment*, is the obtaining the poſſeſſion of any thing recovered by judgment of law. There are two ſorts of executions; one final, another with a quouſque, as only tending to an end.

Final EXECUTION, is that which maketh money of the defendant's goods, or extendeth his lands, and delivers them to the plaintiff; for this the party accepts in ſatisfaction; and this is the end of the ſuit, and all that the king's writ commands to be done.

EXECUTION *with a Quouſque*, is that which only tends to an end; as in the caſe of a *capias ad ſatisfaciendum*, &c. This is not final; but the body of the party is to be taken, to the intent and purpoſe to ſatisfy the plaintiff; and his impriſonment is not abſolute, but till he doth ſatisfy; ſo that the body is but a pledge for the debt.

Executions are either in perſonal, real, or mixed actions. In a perſonal action, the execution may be made three ways, viz. by the writ of *capias ad ſatisfaciendum*, againſt the body of the defendant; *fieri facias*, againſt his goods; or *elegit*, againſt his lands. In a real and mixed action, the execution is by writ of *habere facias ſeiſinam, and habere facias poſſeſſionem.*

Military EXECUTION is the pillage or plundering of a country by the enemies army.

Military EXECUTION, alſo denotes every kind of puniſhment inflicted on an army by ſentence of a court martial. This is of various kinds; as tying up to three halberts, and receiving a number of laſhes with a whip, compoſed of nine cord laſhes, and each laſh of nine knots, from the drummer. When a ſoldier is to be puniſhed with death, a detachment of about two hundred men from the regiment to which he belongs forms the parade, and a file of grenadiers ſhoots the priſoner to death.

EXECUTION, in criminal caſes, the completion of human puniſhment. This follows judgment, and muſt in all caſes, capital as well as otherwiſe, be performed by a legal officer, the ſheriff or his deputy; whoſe warrant for ſo doing was anciently by precept under the hand and ſeal of a judge, as it is ſtill practiſed in the court of the lord high ſteward, upon the execution of a peer: though, in the court of the peers in parliament, it is done by writ from the king. Afterwards it was eſtabliſhed, that, in caſe of life, the judge may command execution to be done without any writ. And now the uſage is, for the judge to ſign the calendar or liſt of all the priſoners names, with their ſeparate judgments in the margin, which is left with the ſheriff. As, for a capital felony, it is written oppoſite to the priſoner's name, " let him be hanged by the neck;" formerly, in the days of Latin abbreviation, "*Juſ. per coll.*" for "*Juſpendatur per collum.*" And this is the only warrant that the ſheriff has, for ſo material an act as taking away the life of another. It may certainly afford matter of ſpeculation, that in civil cauſes there ſhould be ſuch a variety of writs of execution to recover a trifling debt, iſſued in the king's name, and under the ſeal of the court, without which the ſheriff cannot legally ſtir one ſtep; and yet that the execution of a man, the moſt important and terrible taſk of any, ſhould depend upon a marginal note.

The ſheriff, upon receipt of his warrant, is to do execution within a convenient time; which in the country is alſo left at large. In London, indeed, a more ſolemn and becoming exactneſs is uſed, both as to the warrant of execution, and the time of executing thereof: for the recorder, after reporting to the king in perſon the caſe of the ſeveral priſoners, and receiving his royal pleaſure, that the law muſt take its courſe, iſſues his warrant to the ſheriffs, directing them to do execution on the day and at the place aſſigned. And in the court of king's bench, if the priſoner be tried at the bar, or brought there by *habeas corpus*, a rule is made for his execution; either ſpecifying the time and place, or leaving it to the diſcretion of the ſheriff. And, throughout the kingdom, by ſtatute 25 Geo. II. c. 37. it is enacted that, in caſe of murder, the judge ſhall in his ſentence direct execution to be performed on the next day but one after ſentence paſſed. But, otherwiſe, the time and place of execution are by law no part of the judgment. It has been well obſerved, that it is of great importance, that the puniſhment ſhould follow the crime as early as poſſible; that the proſpect of gratification or advantage, which tempts a man to commit the crime, ſhould inſtantly awake the attendant idea of puniſhment. Delay of execution ſerves only to ſeparate theſe ideas: and then the execution itſelf affects the minds of the ſpectators rather as a terrible ſight, than as the neceſſary conſequence of tranſgreſſion.

The ſheriff cannot alter the manner of the execution, by ſubſtituting one death for another, without being guilty of felony himſelf. It is held alſo by Sir Edward Coke and Sir Matthew Hale, that even the king cannot change the puniſhment of the law, by altering the hanging or burning into beheading; though, when beheading is part of the ſentence, the king may remit the reſt. And notwithſtanding ſome examples to the contrary, Sir Edward Coke ſtrongly maintains, that *judicandum eſt legibus, non exemplis*. But others have thought, and more juſtly, that this prerogative, being founded in mercy, and immemorially exerciſed by the crown, is part of the common law. For hitherto, in every inſtance, all theſe exchanges have been for more merciful kinds of death; and how far this may alſo fall within the king's power of granting conditional pardons, (viz. by remitting a ſevere kind of death, on condition that the criminal ſubmits to a milder) is a matter that may bear conſideration. It is obſervable, that when Lord Stafford was executed for the popiſh plot in the reign of king Charles II. the then ſheriffs of London, having received the king's writ for beheading him, petitioned the houſe of lords, for a command or order from their lordſhips, how the ſaid judgment ſhould be executed: for, he being proſecuted by impeachment, they entertained a notion (which is ſaid to have been countenanced by Lord Ruſſel), that the king could not pardon any part of the ſentence. The lords reſolved, that the ſcruples of the ſheriffs were unneceſſary; and declared, that the king's writ ought to be obeyed. Diſappointed of raiſing a flame in that aſſembly, they immediately ſignified to the houſe of commons by one of the members, that they were not ſatisfied as to the power of the ſaid writ. That houſe took two days to conſider of it; and then ſullenly reſolved, that the houſe was content that the ſheriff do execute Lord Stafford by ſevering his head from his body. It is farther related, that when afterwards the ſame Lord Ruſſel was condemned for high treaſon upon indictment, the king, while he remitted the ignominious part of the ſentence, obſerved, "that his Lordſhip would now find he was poſſeſſed of that prerogative, which in the caſe of Lord Stafford he had denied him." One can hardly determine (at this diſtance from thoſe turbulent times), which moſt to diſapprove of, the indecent and ſanguinary zeal of the ſubject, or the cool and cruel ſarcaſm of the ſovereign,

To conclude: it is clear, that if, upon judgment to be hanged by the neck till he is dead, the criminal be not thoroughly killed, but revives, the ſheriff muſt hang him again. For the former hanging was no execution of the ſentence; and, if a falſe tenderneſs were to be indulged in ſuch caſes, a multitude of colluſions might enſue. Nay, even while abjurations were in force, ſuch a criminal, ſo reviving, was not allowed to take ſanctuary and abjure the realm; but his fleeing to ſanctuary was held an eſcape in the officer.

EXECUTIVE *Power*, ſupreme, is by the conſtitution of theſe kingdoms lodged in a ſingle perſon, the king or queen, for the time being.

EXECUTOR, a perſon nominated by a teſtator, to take care to ſee his will and teſtament executed or performed, and his effects diſpoſed of according to the tenor of the will. The appointment of an executor, either by expreſs words, or by ſuch as ſtrongly imply the ſame, is eſſential to the making of a will; but if the teſtator names no executors, or names incapable perſons, or if the executors that are named refuſe to act, the ordinary muſt grant letters of adminiſtration.

A perſon appointed to be executor is not compellable to execute the will; he may refuſe the charge, before he has adminiſtered as executor, or performed ſuch acts, as paying debts due by the teſtator, or receiving debts due to him, or giving acquittances for the ſame; but if he meddles with the goods of the teſtator, as executor, his ſubſequent refuſal is void, and he ſhall be charged as executor. A perſon to whom a legacy is left may be compelled either to ſtand the executorſhip, or to reſign his legacy. The refuſal of executorſhip muſt be entered and recorded in court. If ſeveral executors are named in a will, and ſome of them refuſe, and others prove the will, they who refuſe may afterwards adminiſter and act; and they muſt be joined in all ſuits, where the co-executors are plaintiffs; but not where they are defendants, becauſe the plaintiff in the action is not bound by law to take notice of any beſides thoſe who have proved the will.

As to the office or duty of an executor, it is to be obſerved that he may do many things before he proves the will, which an adminiſtrator cannot do; becauſe the former derives his power from the will, and not from the probate, or appointment of the ordinary, as the latter does. He may maintain actions of treſpaſs, replevin, or detinue, releaſe an action, aſſent to a legacy, be ſued, alien, or otherwiſe intermeddle with the goods of the teſtator: by adminiſtrating, the executor is entitled to receive all debts due to the teſtator, and all payments made to him are good, though he ſhould die, and never prove the will; but he cannot maintain a ſuit or action of debt, or the like, before he has proved the will. The ordinary, &c. may cite the executor, either to prove the will, or refuſe the office; and he may ſequeſter the goods of the deceaſed, till the executor has proved it; and if he does not appear on the proceſs, the ordinary may excommunicate him. On the other hand, the ordinary is compelled by mandamus to proceed to probate, when the will is not controverted. The executor muſt bury the deceaſed in a manner ſuitable to the eſtate he leaves behind him; neceſſary funeral expences are allowed, previous to all other debts and charges; but if he be extravagant, he is chargeable with devaſtation, or waſte of the ſubſtance of the deceaſed, which ſhall be only prejudicial to himſelf, and not to the creditors or legatees of the deceaſed. He is then to make an inventory of all the goods and chattles, whether in poſſeſſion or action of the deceaſed, which he is to deliver in to the ordinary upon oath, if lawfully required, at the time of probate. He is then to collect all the goods and chattels ſo inventoried; for which purpoſe the law confers on him ample powers, as the repreſentative of the deceaſed; and having the ſame property in his goods as the principal had when living, and the ſame remedies to recover them; and if there be two or more executors, a ſale or releaſe by one of them ſhall be good againſt all the reſt. The executor muſt in the next place pay the debts of the deceaſed, in the order of their priority.

If no ſuit is commenced againſt him, the executor may pay any one creditor in equal degree his whole debt, though he has nothing left for the reſt; for, without a ſuit commenced, the executor has no legal notice of the debt. After the debts, the executor is to pay the legacies, which he is to pay as far as his aſſets will extend; but he may not give himſelf the preference herein, as in the caſe of debts. In caſe of a deficiency of aſſets all the general legacies muſt abate proportionably, in order to pay the debts; but a ſpecific legacy, as of a piece of plate, houſe, &c. is not to abate at all, unleſs there be not ſufficient without it. If the legatees have been paid their legacies, and debts come in more than enough to exhauſt the reſiduum, they are afterward bound to refund a ratable part.

When all the debts and legacies are diſcharged, the ſurplus or reſiduum muſt be paid to the reſiduary legatee, if any be appointed by the will; if there be none, it was formerly underſtood to belong to the executor; but it ſeems to be now the general opinion, that, if there be an expreſs legacy given to an executor, and no deviſe of the ſurplus, ſuch ſurplus ſhall not go to the executor, but be diſpoſed to the next of kin, according to the ſtatute of diſtributions; the executor ſtanding on the ſame footing as an adminiſtrator.

Where no expreſs legacy is given to the executor, the ſurplus ſhall go to the executor, if not otherwiſe diſpoſed of by will. When there are ſeveral executors, and ſome of them are dead, the legatory muſt ſue the ſurviving executors, and not the executors or adminiſtrators of thoſe that are dead. And if all the executors are dead, he muſt ſue the executors or adminiſtrators of thoſe that died laſt, and not thoſe of the reſt.

EXECUTORY, that which has, or carries with it a ſufficient authority for being executed. A contract is only executory, when it is in form, and ſealed: the great ſeal of England is executory throughout the whole iſland.

EXEMPLAR, a model, or original, to be imitated, or copied. Exemplar alſo denotes the idea, or image, conceived, or formed in the mind of the artiſt, whereby he conducts his work. Such is the idea of Cæſar, which a painter has in his mind when he goes to make a picture of Cæſar.

EXEMPLIFICATION *of Letters Patent*, denotes an exemplar, or copy of letters patent, made from the inrollment thereof, and ſealed with the great ſeal of England. Such exemplifications are as effectual to be ſhewed, or pleaded, as the letters patent themſelves.

EXEMPTION, a privilege, or diſpenſation, whereby a perſon is excepted out of ſome general rule.

Exemption, in law, denotes a privilege to be free from ſervice or appearance; thus knights, clergymen, &c. are exempted from appearing at the county courts by ſtatute, and peers from ſerving on inqueſts. Perſons ſeventy years of age, apothecaries, &c. are alſo exempted by law from ſerving on juries, and juſtices of peace, attornies, &c. from pariſh offices.

EXERCISE, a repetition of any operation for the ſtrengthening, or retaining of a habit. Thus we uſe exerciſe of the body for acquiring, or maintaining health; as it contributes both to the expulſion of the excrements, and preſerving the tone and ſpring of the ſolids. People who lead a ſedentary life, and do not uſe exerciſe, are liable to an univerſal relaxation of the ſolids, which brings on other diſorders, glandular obſtructions, weak nerves, and defect of perſpiration.

Exerciſe may be continued to a beginning of wearineſs, and ought to be uſed before dinner in a pure light air; for which reaſon, journeys, and going into the country, contribute greatly to preſerve and re-eſtabliſh health. Exerciſe increaſes the circulation of the blood, attenuates and divides the fluids, and promotes a regular perſpiration, as well as a due ſecretion of all the humours: for it accelerates the animal ſpirits, and facilitates their diſtributing into all the fibres of the body, ſtrengthens the parts, creates an appetite, and helps digeſtion. Whence it ariſes, that thoſe who accuſtom themſelves to exerciſe are generally very robuſt, and ſeldom ſubject to diſeaſes.

Boerhaave recommends bodily exerciſe in diſeaſes of a weak and lax fibre. By riding on horſeback, ſays his commentator, the pendulous viſcera of the abdomen are ſhaken every moment, and gently rubbed as it were one againſt another, while in the mean time the pure air acts on the lungs with greater force. But it is to be obſerved, that a weak man ſhould not ride with a full ſtomach, but either before dinner, or after the digeſtion is near finiſhed; for when the ſtomach is diſtended, weak people do not bear theſe concuſſions of the horſe without difficulty; but when the primæ viæ are near empty, the remaining feces are diſcharged by this concuſſion. Sailing in a ſhip is alſo an exerciſe of great uſe to weak people. If the veſſel moves with an even motion, by increaſing perſpiration it uſually excites a wonderful alacrity, creates an appetite, and promotes digeſtion. Theſe exerciſes are more eſpecially ſerviceable to weak people; but, in order to ſtrengthen the body by muſcular motion, running and bodily exerciſes are to be uſed. In theſe we ſhould begin with the moſt gentle, ſuch as walking, and increaſe it by degrees till we come to running. Thoſe exerciſes of the body are more eſpecially ſerviceable which give delight to the mind at the ſame time, as tennis, fencing, &c.; for which reaſon, the wiſdom of antiquity appointed rewards for thoſe who excelled in theſe gymnaſtic exerciſes, that by this means the bodies of their youth might be hardened for warlike toils.

As nothing is more conducive to health than moderate exerciſe, ſo violent exerciſe diſſipates the ſpirits, weakens the body, deſtroys the elaſticity of the fibres, and exhauſts the fluid parts of the blood. No wonder, then, that acute and mortal fevers often ariſe from too violent exerciſe of the body; for the motion of the venous blood towards the heart being quickened by the contraction of the muſcles, and the veins being thus depleted, the arteries more eaſily propel their contained humours through the ſmalleſt extremities into the now leſs reſiſting veins; and therefore the velocity of the circulation will be increaſed through all the veſſels. But this cannot be performed without applying the humours oftener, or in a greater quantity, to the ſecretory organs in the ſame time, whence the more fluid parts of the blood will be diſſipated, and what remains will be inſpiſſated; and by the greater action of the veſſels upon their contained fluids, and of the reacting fluids upon the veſſels, the blood acquires an inflammatory denſity. Add to this, that by the violent attrition of the ſolids and fluids, together with the heat thence ariſing, all the humours will incline to a greater acrimony, and the ſalts and oils of the blood will become more acrid and volatile. Hence, ſays Boerhaave, thoſe fevers which ariſe from too much exerciſe or motion, are cured by reſt of body and mind, with ſuch aliments and medicines as moiſten, dilute, and ſoften or allay acrimony.

Labour or exerciſe, Dr. Cheyne obſerves, is indiſpenſably neceſſary to preſerve the body any time in due plight. Let any diet be purſued, however adjuſted, both in quantity and quality; let whatever evacuations be uſed to leſſen the malady, or any ſuccedaneum be propoſed to prevent the ill effects, ſtill our bodies are ſo made, and the animal œconomy is ſo contrived, that, without due labour and exerciſe, the juices will thicken, the joints will ſtiffen, the nerves will relax; and, from theſe diſorders, chronical diſeaſes, and a crazy old age, muſt enſue. Eſſay on Health, p. 90.

Of all the exerciſes that are, or may be, uſed for health, as walking, riding on horſeback, or in a coach, fencing, dancing, bowling, digging, pumping, ringing, &c. walking is the moſt natural, and would be the moſt uſeful, if it did not ſpend too much of the ſpirits of the weakly. But riding is certainly the moſt manly, the moſt healthy, and is leſs laborious and expenſive of ſpirits than any.

It is generally ſaid that riding is a more healthful exerciſe than walking; which appears to be an aſſertion a little too general; for walking is much more effectual in promoting an increaſe of muſcular ſtrength, and in imparting to the fibres a due elaſticity, than riding. But where any of the viſcera are much obſtructed, and a patient is too weak to ſupport ſufficient walking exerciſe, in ſuch caſe riding may be more beneficial. Upon the whole, it may be ſaid, that walking is beſt for the preſervation of health, but riding for the relief of chronical diſtempers; for in thoſe which are acute, neither of them is adviſeable.

Thoſe organs of the body that are moſt uſed, always become ſtrongeſt; ſo that we may ſtrengthen any weak organ by exerciſe. Thus the legs, thighs, and feet of chairmen; the arms and hands of watermen; the backs and ſhoulders of porters, grow thick, ſtrong, and brawny, by time and uſe. It is certain, alſo, that ſpeaking ſtrong and loud will ſtrengthen the voice, and give force to the lungs. To the aſthmatic, therefore, and thoſe of weak lungs, I would recommend, ſays Dr. Cheyne, talking much and loud; walking up eaſy aſcents, &c. to thoſe of weak nerves, and digeſtion, riding on horſeback; to thoſe troubled with the ſtone, riding over rough cauſeways in a coach; to thoſe troubled with rheumatic pains, playing at billiards, cricket, or tennis; to thoſe of weak arms, or hams, playing at tennis, or football; to thoſe of weak backs, or breaſts, ringing a bell, or working at the pump. Walking through rough roads, even to laſſitude, will beſt recover the uſe of the limbs to the gouty; though riding will beſt prevent the diſeaſe; but the ſtudious, the contemplative, the valetudinary, and thoſe of weak nerves, muſt make exerciſe a part of their religion. A condition neceſſary to render exerciſe as beneficial as may be, is, that it may be uſed on an empty ſtomach. Under the head of exerciſe, cold bathing, and the fleſh-bruſh come alſo to be recommended.

EXERCISE, in the art of war, denotes the ranging of a body of ſoldiers in form of battle, and making them practiſe the ſeveral motions, and military evolutions, with the diverſe management of their arms, &c. to make, or keep them expert therein againſt occaſion.

Manual EXERCISE, conſiſts in the obſervance of certain words of command appointed for this purpoſe. See MILITARY *Exerciſe*.

EXERCISE, in a naval ſenſe. See NAVAL *Exerciſe*.

EXERCISES are alſo underſtood of what young perſons learn in the academies and riding ſchools, ſuch as fencing, drawing, riding, &c. How uſeful, how agreeable ſoever, ſtudy may be to the mind, it is very far from being equally ſalutary to the body. Every one obſerves, that the Creator has formed an intimate connexion between the body and the mind; a perpetual action and reaction, by which the body inſtantly feels the diſorders of the mind, and the mind thoſe of the body. The delicate ſprings of our frail machines loſe their activity and become enervated, and the veſſels are choked by obſtructions when we totally deſiſt from exerciſe, and the conſequences neceſſarily affect the brain: a more ſtudious and ſedentary life is therefore equally prejudicial to the body and the mind. The limbs likewiſe become ſtiff; we contract an aukward conſtrained manner; a certain diſguſtful air attends all our actions, and we are very near being as diſagreeable to ourſelves as to others. An inclination to ſtudy is highly commendable; but it ought not, however, to inſpire us with an averſion to ſociety. The natural lot of man is to live among his fellows: and whatever may be the condition of our birth, or our ſituation in life, there are a thouſand occaſions where a man muſt naturally deſire to render himſelf agreeable; to be active and adroit; to dance with a grace; to command the fiery ſteed; to defend himſelf againſt a brutal enemy; to preſerve his life by dexterity; as by leaping, ſwimming, &c. Many rational cauſes have therefore given riſe to the practice of particular exerciſes, and the moſt ſagacious and benevolent legiſlators have inſtituted, in their academies and univerſities, proper methods of enabling youth, who devote themſelves to ſtudy, to become expert alſo in laudable exerciſes.

EXFOLIATION, compounded of *ex* and *folium*, *leaf*, in ſurgery, the ſcaling of a bone; or its riſing, and ſeparating in leaves, or laminæ. Any part of the ſurface of the cranium that has been bared, is liable to exfoliation. The wound muſt not be ſtopped too much, but the bone left at liberty to recover itſelf, which it ſometimes does, without exfoliating, particularly in children.

EXFOLIATIVE. An exfoliative trepan is a trepan proper to ſcrape, and at the ſame time pierce, a bone, and ſo to exfoliate, or raiſe, ſeveral leaves, or ſcales, one after another. The uſe of the exfoliative trepan is very dangerous; as being apt to ſhake and diſorder the brain.

EXHALATION, a fume, or ſteam, exhaling, or iſſuing, from a body, and diffuſing itſelf in the atmoſphere. The terms exhalation and vapour are ordinarily uſed indifferently, but the more accurate writers diſtinguiſh them; appropriating the term vapour to the moiſt fumes raiſed from water and other liquid bodies; and exhalation to the dry one emitted from ſolid bodies; as earth, fire, minerals, ſulphurs, ſalts, &c. In this ſenſe, exhalations are dry, ſubtil corpuſcles, or effluvia, looſened from hard terreſtrial bodies, either by the heat of the ſun, or the agitation of the air or ſome other cauſe; and emitted upwards to a certain height of the atmoſphere, where, mixing with the vapours, they help to conſtitute clouds, and return back again in dews, miſts, rains, &c. Sir

Iſaac Newton takes true and permanent air to be formed from the exhalations raiſed from the hardeſt and moſt compact bodies.

EXHAUSTED *Receiver*, a glaſs, or other veſſel, applied on the plate of an air-pump, and having the air extracted out of it by the working of the engine. Things placed in an exhauſted receiver, are ſaid to be in vacuo. See Syſtem of PNEUMATICS, Plate III. *Fig.* II.

EXHIBITION, in a general ſenſe, the act of diſplaying, explaining, or rendering viſible; the act of expoſing to public view; alſo a producing, or ſhewing, of titles, authorities, and other proofs, on a matter in conteſt. Anciently, they uſed the phraſe, exhibition of a tragedy, comedy, or the like; but now we ſay repreſentation, in lieu thereof.

EXIGENCE, or EXIGENCY, that which a thing requires, or which is expedient and ſuitable thereto.

EXILE is uſed for the delegating a perſon into a place, whence he is obliged not to ſtir without leave. The word is derived from the Latin *exilium*, or from *exul*, a baniſhed perſon; and that, probably, from *extra ſolum*, out of his native ſoil. Figuratively, we uſe the phraſe, honourably exile, for an office, or employment, which obliges a man to reſide in ſome remote and diſagreeable place.

EXISTENCE, that whereby a thing has an actual eſſence, or is ſaid to be. See METAPHYSICS.

EXIT, properly expreſſes the departure of a player from off the ſtage, when he has acted his part. The word is alſo uſed in a figurative ſenſe, to expreſs any kind of departure, even death.

EXITUS, iſſues in law, the yearly rents or profits of lands or tenements, &c.

EXOCOETUS, or the FLYING-FISH, in ichthyology, a genus belonging to the order of abdominales. The head is ſcaly, and it has no teeth. It has 10 radii in the branchioſtege membrane; the body is whitiſh, and the belly is angular; the pectoral fins, the inſtruments of flight, are very large. When purſued by any other fiſh, it raiſes itſelf from the water by means of theſe long fins, and flies in the air to a conſiderable diſtance, till the fins dry, and then it falls down into the water. It is a fiſh that ſeems to lead a moſt miſerable life. In its own element, it is perpetually haraſſed by the dorados and other fiſh of prey. If it endeavours to avoid them by having recourſe to the air, it either meets its fate from the gulls, or the albatroſs, or is forced down again into the mouth of the inhabitants of the water, who, below, keep pace with its aerial excurſion. Neither is it unfrequent that whole ſhoals of them fall on board of ſhips that navigate the ſeas in warm climates. It is therefore apparent, that nature in this creature hath ſupplied it with inſtruments which frequently bring it into the deſtruction it ſtrives to avoid, by having recourſe to an element unnatural to it.

EXODIUM, in the ancient Greek drama, one of the four parts or diviſions of tragedy, being ſo much of the piece as included the cataſtrophe and unravelling of the plot, and anſwering nearly to our fourth and fifth acts.

EXODIUM, in the Septuagint, ſignifies the end or concluſion of a feaſt. Particularly it is uſed for the eighth day of the tabernacles, which, it is ſaid, had a ſpecial view to the commemoration of the exodus or departure out of Egypt.

EXODUS, a canonical book of the Old Teſtament; being the ſecond of the pentateuch, or five books of Moſes. It is ſo called from the Greek [Εξοδος], the going out or departure of the children of Iſrael from the land of Egypt; the hiſtory of which is delivered in this book, together with the many miracles wrought on that occaſion.

EX OFFICIO, denotes the power a perſon has in virtue of his office, to do certain things without being applied to. By a branch of ſtatute 1 Eliz. the queen, by her letters patent, might authoriſe any perſons exerciſing eccleſiaſtical juridiction to adminiſter an oath, *ex officio*, whereby ſuppoſed offenders were forced to confeſs, accuſe, or clear themſelves of any criminal matter, &c. but this branch relating to this oath is repealed by 17 Car. I. cap. 11.

EXOMPHALUS, in ſurgery, called alſo *omphalocele*, and *hernia umbilicalis*, is a preternatural tumour of the abdomen, at the navel, from a rupture or diſtenſion of the parts which inveſt that cavity.

EXONEIROSIS, from εξ, *out*, and ονειρος, *dream*, a nocturnal emiſſion of the ſemen in dreams. This, if it happens but rarely, is uſually a ſign only of redundant vigour; but if it happens frequently, is a ſign of weakneſs of the ſeminal veſſels, which is moſt frequently the caſe.

EXOPHTHALMIA, of εξ, *out*, and οφθαλμος, *eye*, in ſurgery, is a protuberance of the eye out of its natural poſition.

EXORCISM, among eccleſiaſtical writers, the expelling devils from perſons poſſeſſed, by means of conjurations and prayers. Exorciſm makes a conſiderable part of the ſuperſtition of the church of Rome, the rituals of which forbid the exorciſing any perſon without the biſhop's leave. The ceremony is performed at the lower end of the church, towards the door. The exorciſt firſt ſigns the poſſeſſed perſon with the ſign of the croſs, makes him kneel, and ſprinkles him with holy water. Then follow the litanies, pſalms, and prayers; after which the exorciſt aſks the devil his name, and adjures him by the myſteries of the Chriſtian religion not to afflict the perſon any more; then, laying his right hand on the dæmoniac's head, he repeats the form of exorciſm, which is this; "I exorciſe thee, unclean ſpirit, in the name of Jeſus Chriſt: tremble, O Satan! thou enemy of the faith, thou foe of mankind, who haſt brought death into the world, who haſt deprived men of life, and haſt rebelled againſt juſtice; thou ſeducer of mankind, thou root of evil, thou ſource of avarice, diſcord, and envy." The Romaniſts likewiſe exorciſe houſes and other places, ſuppoſed to be haunted by unclean ſpirits; and the ceremony is much the ſame with that for perſons poſſeſſed.

EXORCISTS, in church hiſtory, an order of men, in the ancient church, whoſe employment it was to exorciſe or caſt out devils. See the preceding article.

EXORDIUM, in oratory, is the preamble or beginning, ſerving to prepare the audience for the reſt of the diſcourſe. Exordiums are of two kinds, either juſt and formal, or vehement and abrupt. The laſt are moſt ſuitable on occaſions of extraordinary joy, indignation, or the like. See Treatiſe on the Art of ORATORY.

EXOSTOSIS, from εξ, *out*, and οςεον, a *bone*, in anatomy, is properly an acute eminence or excreſcence, puſhing preternaturally above the bone, but creating ſometimes no diſturbance, pain, or deformity, and unaccompanied with a caries or ſpina ventoſa. When this is the caſe, it is always beſt to let it alone; for the attempt to remedy often proves much worſe than the diſeaſe; and by laying the bone bare, a caries, or other inconvenience is brought on. On the other hand, when this diſorder occaſions pain or deformity, or impedes any action, or produces other miſchief, it may be remedied by taking off the protuberant part of the bone in the ſame manner as in caſes of *ſpina ventoſa*.

EXOTIC, Εξωτικος, a term properly ſignifying *foreign*, or *extraneous*, i. e. brought from a remote or ſtrange country. In which ſenſe we ſometimes ſay, *exotic*, or *barbarous terms* or *words*, &c. The word is derived from the Greek, εξω, εξωθεν, *extra*, *without*, *on the outſide*.

EXOTIC, is chiefly applied to plants which are natives of foreign countries, particularly thoſe brought from the Eaſt and Weſt Indies, and which do not naturally grow in Europe. The generality of exotics, or exotic plants, do not thrive in England without ſome peculiar care and cultures; they require the warmth of their own climates; whence the uſe of hot beds, glaſs frames, green-houſes, &c.

EXPANSION, in metaphyſics, expreſſes the idea we have of laſting, or preſerving diſtance, i. e. of diſtance, all the parts whereof exiſt together.

EXPANSION, in phyſics, is the dilating, ſtretching, or ſpreading out of a body; whether from any external cauſe as the cauſe of rarefaction, or from an internal cauſe, as elaſticity. Bodies naturally expand by heat beyond their dimenſions when cold, whence their ſpecific gravities are different at the different ſeaſons of the year. Air compreſſed or condenſed, as ſoon as the compreſſing or condenſing force is removed, expands itſelf by its elaſtic power to its former dimenſions.

Spirit of wine, with a heat leſs than that of boiling water, expanded itſelf by one-twelfth part of its bulk, and then began to boil. The moſt ſenſible expanſion of water is in freezing. Mr. Boyle, in his Hiſt. of Cold, aſſures us, that ice takes up one-twelfth part more ſpace than water.

EX PARTE, i. e. *partly*, or of *one part*. A *commiſſion ex parte* is that taken out and executed by one part only: where both parties join, it is called a *joint commiſſion*.

EXPECTANT *Fee*, in law, where lands are given to a man and his wife, and the heirs of their body; in which ſenſe it differs from *fee ſimple*, where lands are given to a man and his wife in frank marriage, to hold to them and their heirs.

EXPECTANCY, *Eſtates in*, are of two ſorts; one created by act of the parties, called a *remainder*; the other by act of law, called a *reverſion*.

EXPECTATION, in the doctrine of chances, is applied to any contingent event, and is capable of being reduced to the rules of computation. Thus, a ſum of money in expectation, when a particular event happens, has a determinate value before that event happens; ſo that if a perſon is to receive any ſum, i. e. 10l. when an event takes place which has an equal probability of happening and failing, the value of the expectation is half that ſum of 5l. and in all caſes, the occaſion of obtaining any ſum is eſtimated by multiplying the value of the ſum expected by the fraction, which repreſents the probability of obtaining it. For the expectation or chance upon cards, dice, lottery, &c. ſee the Article GAMING.

EXPECTATION *of Life*, in the doctrine of life annuities, denotes, according to the moſt obvious ſenſe of the term, that particular number of years which a life of a given age has an equal chance of enjoying, or the time which a perſon of a given age may juſtly expect to continue in being. But Mr. Simpſon has ſhewn, that this period does not coincide with what the writers on annuities call the *expectation of life*, except on the ſuppoſition of an uniform decreaſe in the probabilities of life: and Dr. Price adds, that even on this ſuppoſition, it does not coincide with what is called the *expectation of life*, in any caſe of joint lives; for two lives of 40 have an even chance. See Syſtem of ANNUITIES, Chap. II.

EXPECTORANTS, in pharmacy, are medicines that promote expectoration. See the next *Article*.

EXPECTORATION, of *ex*, *out*, and *pectus*, *breaſt*, the act of evacuating or bringing up phlegm or other matters out of the trachea, lungs, &c. by coughing, hawking, ſpitting, &c. Expectoration eaſes the lungs of the viſcid or putrid matters which obſtruct their veſſels, and ſtraiten the breaſt.

EXPEDITION, in a general ſenſe, quickneſs of time or motion, alſo the march of an army to ſome diſtant place, with a view of hoſtilities. Such were the expeditions of Cyrus againſt Xerxes, and of Bacchus and Alexander from the Indies. Expeditions for the recovery of the Holy Land were called Croiſades.

EXPENDITORS, are perſons appointed by commiſſioners of ſewers, to pay, diſburſe, or expend the money collected by the tax for the repairs of ſewers, &c. when paid into their hands by the collectors on the reparations, amendments, and reformations ordered by the commiſſioners; for which they are to render accounts when required for that purpoſe.

EXPERIENCE, a kind of knowledge acquired by long uſe, without any teacher. Experience conſiſts in the ideas of things we have ſeen or read, which the judgment has reflected on, to form for itſelf a rule or method. Authors make three kinds of experience: the firſt is the ſimple uſes of the external ſenſes, whereby we perceive the phenomena of natural things, without any direct attention thereto, or making any application thereof. The ſecond is, when we premeditatedly and deſignedly make trials of various things, or obſerve thoſe done by others, attending cloſely to all effects and circumſtances. The third is that preceded by a foreknowledge, or at leaſt an apprehenſion of the event, and determines whether the apprehenſion were true or falſe; which two latter kinds, eſpecially the third, are of great ſervice in philoſophy.

EXPERIMENT, in philoſophy, a trial of the effect or reſult of certain applications and motions of natural bodies, in order to diſcover ſomething of the laws and relations thereof, or to aſcertain ſome phenomenon, or its cauſe. The learned define experiment, a compariſon of ſeveral things before obſerved by the ſenſes, and retained in the memory in ſome one ſimilar convenient inſtance.

The nature of experiment, therefore, according to them conſiſts in comparing ſeveral things by one act; whence they diſtinguiſh two things in every experiment, the one material, viz. the ſeveral ideas remembered; the other formal, viz. the comparing of theſe ideas in the mind. This will be illuſtrated by an example: a phyſician gives a quantity of rhubarb to ten ſeveral perſons, and remembers each of them. Now, coming afterwards to compare the ſeveral remembrances together, and finding the effect of the exhibition of rhubarb to be the ſame in all, viz. a purging; this is an experiment of rhubarb.

The making of experiments is grown into a kind of formed art; and we now abound in Syſtems of experiments, under the denomination of courſes of experimental philoſophy. Sturmius has made a curious collection of the principal diſcoveries and experiments of the laſt age, under the title of *collegium experimentale*. Dr. Deſaguliers has alſo publiſhed a comprehenſive and uſeful courſe of experimental philoſophy. The chymiſts chooſe to call their experiment, by way of diſtinction or eminence, *proceſſes* or *operations*.

EXPERIMENTAL PHILOSOPHY.

That philoſophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from ſenſible experiments and obſervations.

I. It is not very long ſince this ſcience has been known to the world, or, to ſpeak more properly, ſince it was firſt reduced into a ſyſtem. Natural philoſophy has been, for theſe 50 centuries, nothing more than a confuſed heap of ſyſtems laid one upon another, and very frequently the one claſhing againſt the other. Each philoſopher thought, that he had an equal right to erect a ſimilar edifice to his own memory. They adopted barbarous terms and expreſſions, that conveyed confuſed ideas only. For explications, they gave certain unintelligible or unmeaning words, which had been introduced by the authority of ſome celebrated name, but from which a man of underſtanding could not receive the leaſt information. At length, the true phyſics was brought to light; it was drawn from the obſcurity of the ſchools, where it had grown old under the authority of Ariſtotle, and ſcarce any thing been ſuffered to remain of it but the name. This reformation proceeded principally from the manner of ſtudying it. Inſtead of gueſſing at it, they began to inveſtigate it by experiments; and whereas they formerly confined themſelves to ſpeculations, and vague reſearches concerning phenomena and their cauſes, that were always merely conjectural, they now gave ocular demonſtrations of cauſes and effects by means of experiments; and this is what they call experimental philoſophy.

II. The principles of this philoſophy are as follow. All the material ſubſtances, whoſe aſſemblage compoſes the univerſe, are called natural bodies. What we perceive in theſe ſubſtances that is uniform and invariable, and of which we do not know the cauſe, is called their properties. Phyſics ſets out with this, as from a fixed point, in order to explain the different phenomena that are perceived on the earth, in the water, the air, or fire, and in all that theſe elements contain. For though it does not pretend to know all that bodies have in common among themſelves, or all that is peculiar to each one of them; yet it knows a certain number of their properties, which it regards as primary, till it diſcovers a precedent cauſe of which they may be the effect; and which properties are general, and in a manner inſeparable from all matter, as for example, *extenſion*. There are likewiſe properties of an inferior order, which do not appertain to all bodies but as they are in certain ſtates, or under certain circumſtances; theſe, in general, are nothing more than combinations of the primary properties; and form a ſecond claſs, as for example, *fluidity*. Laſtly, theſe properties of the firſt and ſecond order combine more and more, and become common to a ſtill ſmaller number of bodies: and here they are no longer extended to all bodies, as the firſt; nor are peculiar to certain ſtates, as the ſecond; but are confined to genders, ſpecies, or even individuals. Such are ſeveral properties of the air, fire, light, metals, the magnet, &c. Theſe three orders of properties are the ſubject of the inquiries of experimental philoſophy, which proves by experiments thoſe that are already known, and frequently diſcovers others that were unknown.

III. It is neceſſary here to deſcend to ſome particulars. The firſt property of bodies, which preſents itſelf to our ideas and our ſenſes, is their extenſion; which is a limited bulk of any form whatever, of which we can conceive parts that may be diſtinguiſhed from each other. This material extenſion has three dimenſions, which are length, breadth, and depth. Every body, whoſe extenſion is large enough to be ſeen or felt, may be divided into ſeveral parts, and which muſt conſequently decreaſe in proportion as the diviſion is encreaſed; from hence comes the infinite diviſibility of matter, at leaſt in idea; for in the ſmalleſt particle we can ſtill imagine two halves, though the fact has never been proved by experiment; for nature does not at all times conform to imagination, ſeeing that the minuteſt particles, and their decompoſition, eſcape our obſervation even in the moſt accurate experiments. However, we ſhould never have believed, without having made the trial, to what degree experimental philoſophy is capable of dividing bodies, and of reducing them to particles that are almoſt indiviſible.

IV. The order, or arrangement, which the ſurfaces of bodies take among themſelves, is called their figures. As theſe ſurfaces cannot be confounded, but are always diſtinguiſhable by their ſituations, it is evident that figure is a common and neceſſary property of all bodies. The experiments by which this truth is demonſtrated by the aid of the microſcope, are equally curious and convincing: and from hence it is alſo proved, that there are no two bodies that are abſolutely ſimilar. The ſolidity of a body is nothing more than the quantity of matter that is contained within its bulk: this property is eſſential to all bodies, and the moſt certain ſign of their exiſtence. Reſiſtance is a neceſſary conſequence of the foregoing property; and every phyſical reſiſtance proves a real ſolidity in a greater or leſs degree. Fluids being the only bodies in which ſolidity is in any manner neceſſary to be proved, it has been there demonſtrated bv numberleſs experiments. The poroſity of bodies is, on the contrary, nothing but that ſpace which is found between their ſolid parts. This ſpace has its degrees. When a dry ſponge is plunged into water, a quantity of air comes out of it, in proportion to the water that penetrates it; and when moiſt bodies are dried, they become more light in proportion as they loſe by evaporation what their poroſity had admitted. This is the firſt ſort of ſpace or vacuum. Light, or the matter of fire that we ſee paſs through bodies impenetrable to air and water, ſuppoſes pores more delicate, and a ſpace more ſubtile. It is almoſt indubitable, that after theſe firſt kinds of vacuum, and which indeed are improperly ſo called, as they are filled with other matter, there are others ſtill ſmaller, and which are ſo in a literal ſenſe. That freedom, which is requiſite to motion, ſeems to prove it; for though we may ſay, matter being diviſible almoſt *ad infinitum*, that a body or ſubſtance more ſolid may move in another ſubſtance that is more ſubtile, and that will give way to its motion, we muſt nevertheleſs have recourſe to a laſt reſort, and admit of an ultimate vacuum, which will give room ſufficient to the leaſt corpuſcle, that its part A may take the place of its part B, without the leaſt reſiſtance; beſides, it is not to be imagined, that nature, in fact, admits of that infinite diviſibility which our imagination can conceive, and that every thing which is poſſible in idea is at all times practicable. All that exiſts is poſſible, but all that is poſſible does not however exiſt. The air-pump is of very great uſe in proving theſe three ſorts of vacuums. By denſity, is underſtood the proportion between the extenſion and ſolidity of a body; one body therefore is more denſe than another, when, under the ſame degree of extenſion, it contains more ſolid matter; and this quality ariſes from condenſation and compreſſion. Elaſticity is nothing more than that effort by which certain bodies, when compreſſed, endeavour to reſtore themſelves to their former ſtate; and this property ſuppoſes them compreſſible. As all theſe natural properties of bodies are of great utility in explaining the principles of phyſics, and in applying them to all the arts, experimental philoſophy proves their reality by a thouſand examples.

V. We diſcover ſtill other properties in bodies; ſuch as mobility, which we muſt not here confound with motion. This mobility ariſes from certain diſpoſitions which are not in an equal degree in all bodies; from whence it comes that ſome are more eaſily moved than others: and this proceeds from the reſiſtance to motion which is perceived in all bodies, having regard merely to their maſſes; and this reſiſtance is called *vis inertiæ*, or *inert force*. A body is ſaid to be in motion, when it is actually moving from one place to another; or, whenever a body changes its ſituation with regard to the objects that ſurround it, either nearly or remotely, it is ſaid to be in motion. There are three principal matters to be conſidered in a moving body; its direction, its velocity, and the quantity of its motion: and here phyſics explains the force or moving power; it likewiſe diſtinguiſhes between ſimple and compound motion. Simple motion is that which ariſes from only one force, or which tends to only one point. It deſcribes the laws, and explains the reſiſtance, of mediums; the reſiſtance of friction; the difficulties of a perpetual motion; the alteration of direction, occaſioned by the oppoſition of a fluid matter; reflected or reverberated motion; the communication of motion by the ſhock of bodies, &c. Compound motion is that of a body impelled to move by ſeveral cauſes or powers which act according to their different directions. Phyſics here likewiſe inveſtigates the laws of motion; and is particularly applied to the explaining, under this head, what are called the *central forces*; which produce a motion that is either circular or in a curve line, and which inceſſantly urge the moving body either to approach or recede from the centre. To diſtinguiſh theſe from each other, the former is called the *centripetal force*, and the latter the *centrifugal force*.

VI. By gravity, or ponderoſity, is to be underſtood that force which occaſions bodies to paſs from a higher to a lower place, when nothing oppoſes their courſe, or when the obſtacles are not ſufficient to ſtop them. Speculative philoſophy inveſtigates its cauſe, and perhaps in vain. Experimental philoſophy contents itſelf with deſcribing the phenomena, and teaching the laws of gravity, which are thoroughly eſtabliſhed by a thouſand reiterated experiments. In order properly to underſtand this ſubject, we muſt take care not to confound the term gravity, with that of weight. By the former, we underſtand that force which urges bodies to deſcend through a certain ſpace in a given time. By the latter, is meant the quantity of a heavy body that is contained under the ſame bulk. The phenomena are explained by the experiments themſelves, and by inferences deduced from them.

VII. Hydroſtatics is a ſcience whoſe object is the gravity and equilibrium of fluids in particular. Though the gravity of theſe bodies is the ſame with that of others, and is ſubject to the ſame laws, yet their ſtate of fluidity gives riſe to particular phenomena, which it is of conſequence to know. But as hydroſtatics cannot be ſucceſsfully treated on without the aſſiſtance of calculation, it has been ranged among the mathematical ſciences. See MATHEMATICS.

VIII. We ſay the ſame with regard to mechanics; which is the art of employing, by the aid of machines, the motion of bodies, in conformity to its properties and laws, as well with regard to ſolids as fluids, either more commodiouſly or more advantageouſly.

IX. After it has made the moſt accurate experiments, and the judicious obſervations, on all theſe different ſubjects, and the properties of bodies in particular, experimental philoſophy paſſes to the examination of the air, the water, fire, the wind, colours, &c. The air is a fluid with which we are ſurrounded from the inſtant of our birth, and without which we cannot exiſt. It is by the properties and the influences of the air, that nature gives increaſe and perfection to all that it produces for our wants and conveniencies; it is the ſpirit of navigation: ſound, voice, ſpeech itſelf, are nothing more than percuſſions of the air: this globe that we inhabit is completely ſurrounded by air; and this kind of coverture, which is commonly called the atmoſphere, has ſuch remarkable functions, that it evidently appears to concur to the mechaniſm of nature. Experimental phyſics, therefore, conſiders the air, 1. Of itſelf, independent of its bulk, and the figure of its whole body: it examines its eſſential properties; as its gravity, denſity, ſpring, &c. The air pump is here of indiſpenſable uſe; and by this machine phyſics examines in what manner ſpace, or a vacuum, is made. It likewiſe ſhows the neceſſity of air to the preſervation of animal life; the effect it has on ſound, fire, and gunpowder, *in vacuo*; and a hundred other experiments of various degrees of curioſity. 2. It conſiders the air as the terreſtrial atmoſphere, ſometimes as a fluid at reſt, and ſometimes as in motion. And by theſe means it accounts for the variation of the mercury in the barometer, and why it ſinks in proportion as the height of the atmoſphere diminiſhes; as alſo for the figure, the extent, and weight of the atmoſphere: it ſhews the method of determining the height of mountains, the nature of ſound in general, of its propagation, and of ſonorous bodies.

X. It is here alſo, that experimental philoſophy conſiders the nature of the wind; which is nothing more than agitated air, a portion of the atmoſphere that moves like a current, with a certain velocity and determinate direction. This fluid, with regard to its direction, takes different names according to the different points of the horizon from whence it comes, as Eaſt, Weſt, North, and South. Winds are likewiſe diſtinguiſhed into three ſorts; one of which is called general or conſtant, as the trade-winds, which continually blow between the tropics: another is the periodical, which always begin and end within a certain time of the year, or a certain hour of the day, as the monſoons, the land breezes, and ſea breezes, which riſe conſtantly in the morning and evening; and laſtly, ſuch as are variable, as well with regard to their direction as their velocity and duration.

M. Mariotte computes the velocity of the moſt impetuous wind, to be at the rate of 32 feet in a ſecond, and Mr. Derham makes it 66 feet in the ſame time. The firſt, doubtleſs, meant the wind of the greateſt velocity that had then come to his knowledge.

XI. The force of the wind, like that of other bodies, depends on its velocity and maſs; that is, the quantity of air which is in motion: ſo the ſame wind has more or leſs force on any obſtacle that oppoſes it, in proportion as that obſtacle preſents a greater or a leſs ſurface: for which reaſon it is that they ſpread the ſails of a veſſel more or leſs, and place the wings of a wind mill in different directions. The machines, by which the winds are meaſured, are called anemometers. They ſhew the direction, the velocity, and the duration of winds. It is by the agitations of the wind, that the air is purified; that the ſeeds of trees and herbs are conveyed to the foreſts and fields; that ſhips are driven from one pole to the other; that our mills turn upon their axes, &c.; and art, by imitating nature, ſometimes procures us artificial winds, by which we refreſh our bodies, invigorate our fires, purify our corn, &c.

XII. Water is an univerſal agent, which nature employs in all her productions. It may be conſidered as in three ſtates, 1. As a liquid; 2. As a vapour; 3. As ice. Theſe three different ſtates do not in any manner change its eſſence, but make it proper to anſwer different ends. The natural ſtate of water would be that of a ſolid body, as fat, wax, and all thoſe other bodies which are only fluid when heated to a certain degree: for water would be conſtantly ice, if the particles of fire, by which it is penetrated in the temperate climates, did not render it fluid, by producing a reciprocal motion among its parts; and, in a country where the cold is continually ſtrong enough to maintain the congelation, the aſſiſtance of art is neceſſary to make it fluid in the ſame manner as we do lead, &c. Water, when not in ice, is a fluid that is inſipid, tranſparent, without colour, and without ſmell, aud that eaſily adheres to the ſurface of ſome bodies, that penetrates many, and extinguiſhes fire. Experimental philoſophy inveſtigates the origin of fountains; the cauſe of the ſaltneſs of the ſea; the means of purifying water; what is its weight, and what are its effects when heated, &c. It likewiſe examines this fluid in the ſtate of vapour; and, finds that a drop of water, when in vapour, occupies a ſpace vaſtly greater than it did before. It explains the *æolipile* and its effects: fire engines; and the force of vapours that give motion to immenſe machines in mines and elſewhere, &c. and laſtly, it conſiders water in the ſtate of ice. Ice conſequently is more cold than water; and its coldneſs increaſes if it continue to loſe that matter, already too rare, or too little active, to render it fluid. Experimental phyſics endeavours to inveſtigate the cauſes of the congelation of water, and why ice is lighter than water; from whence it derives that expanſive force by which it breaks the containing veſſel; the difference there is between the congelation of rivers and that of ſtanding waters; why ice becomes more cold by the mixture of ſalts: and many other ſimilar phenomena.

XIII. The nature of fire is yet very much unknown to the moſt learned philoſophers. As objects when at a great diſtance are not perceptible to our ſenſes, ſo when we examine them too nearly, we diſcern them but confuſedly. It is ſtill diſputed whether fire be a homogene, unalterable matter, deſigned, by its preſence, or by its action, to produce heat, inflammation, and diſſolution, in bodies; or if its eſſence conſiſts in motion only, or in the fermentation of thoſe particles which we call inflammable, and which enter as principles, in greater or leſs quantities, in the compoſition of mixed bodies. The moſt learned inquirers into nature incline to the former opinion; and to have recourſe to a matter, which they regard as the principle of fire. They ſuppoſe that there is in nature a fluid adapted to this purpoſe, created ſuch from the beginning, and that nothing more is neceſſary than to put it in action. The numberleſs experiments which are daily made in electricity, ſeem to favour this opinion, and to prove that this matter, this fluid, this elementary fire, is diffuſed through all nature, and in all bodies, even ice itſelf. We cannot ſay to what important knowledge this great diſcovery of electricity may lead if we continue our inquiries concerning it. It appears, however, that we may believe, without any inconvenience or abſurdity, that fire and light, conſidered in their firſt principle, are one and the ſame ſubſtance differently modified.

XIV. Be this matter however as it may, experimental philoſophy is employed in making the moſt ingenious and moſt uſeful reſearches concerning the nature of fire, its propagation, and the means by which its power may be excited or augmented; concerning the phoſphorous and its inflammation; fire excited by the reflection of the ſun's rays from a mirror; and on the effects of fire in general; concerning lightning and its effects; the fuſion of metals; gunpowder and its exploſion; flame, and the aliments of fire; and an infinity of like objects which it explains, or concerning which it makes new diſcoveries, by the aid of experiment.

XV. By the word *light*, we underſtand that agent by which nature affects the eye with that lively, and almoſt conſtantly pleaſing ſenſation, which we call ſeeing, and by which we diſcern the ſize, figure, colour, and ſituation of objects, when at a convenient diſtance. All philoſophers agree, that the light, which is diffuſed in any place, is a real body. But what this body is, and by what means it enters that place where it is perceived, is a queſtion about which philoſophers are divided.

XVI. Experimental philoſophy is applyed in diſcovering or proving, by an infinity of experiments, what is the nature of light, in what manner it is propagated, what its velocity and progreſſive motion. It alſo inveſtigates and explains the principles of optics, properly ſo called, and ſhews the directions which light obſerves in its motions. From thence it proceeds to the examen of the principles of catoptrics, and deſcribes the laws and effects of reflected light. It next treats of the principles of dioptrics, and explains the laws of refracted light: and laſtly, it teaches, from the principles of natural and artificial viſion, the conſtruction of optical inſtruments, as lenſes, concave mirrors, priſms, teleſcopes, &c. &c. and the uſes to which they are applied.

XVII. By reſolving or ſeparating the rays of light, philoſophy has obtained true and clear diſcoveries of the nature of colours. We are naturally led to imagine that colours, and their different degrees, make a part of the bodies that preſent them to our ſight; that white is inherent in ſnow, green in leaves and graſs, and red in a ſtuff dyed of that colour. But this is far from being true. If an object, which preſents any colour to our ſight, be not illuminated, it preſents no colour whatſoever. In the night all is black. Colours, therefore, depend on light; for without that we could form no idea of them: but they depend alſo on bodies; for of ſeveral objects preſented to the ſame light, ſome appear white, others red, blue, &c. But all theſe matters being ſeparate from our own bodies, we ſhould never acquire any ideas of them, if the light, tranſmitted or reflected by theſe objects, did not make them ſenſible to us, by ſtriking upon the organs of our ſight, and if theſe impreſſions did not revive in us thoſe ideas which we have been uſed to expreſs by certain terms. For theſe reaſons philoſophy conſiders colours from three points of view, 1. As in the light; 2. In bodies, as being coloured; and, 3. From the relation they have to our viſual faculties, which they particularly affect, and by which we are enabled to diſtinguiſh them.

It is unneceſſary in this place to ſay more either on colour in particular, or experimental philoſophy in general. The different ſubjects of this collective article are particularly treated under their proper names, in the order of the alphabet: the reader will therefore turn, as he has occaſion, to ACOUSTICS, CATOPTRICS, DIOPTRICS, HYDROSTATICS, MECHANICS, OPTICS, PNEUMATICS, ELECTRICITY, MAGNETISM, &c. &c. &c.——Alſo AIR, BURNING-*Glaſs*, COLD, COLOUR, CONGELATION, EVAPORATION, FIRE, FLAME, FLUIDITY, HEAT, IGNITION, LIGHT, SOUND, STEAM, WATER, WIND, &c.

EXPERIMENTUM CRUSIS, a capital, leading, or deciſive experiment; thus termed, either on account of its being like a croſs, or direction poſt, placed in the meeting of ſeveral roads, guiding men to the true knowledge of the nature of that thing they are inquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is as it were extorted by force.

EXPIATION, a religious act, by which ſatisfaction, atonement, or amends, is made for the commiſſion of ſome crime, the guilt done away, and the obligation to puniſhment cancelled. The method of expiation among the Jews was chiefly by ſacrifice, whether for ſins of ignorance, or to purify themſelves from certain pollutions.

Great Day of EXPIATION, an annual ſolemnity of the Jews, upon the tenth day of the month Tiſri, which anſwers to our September. On this occaſion, the high prieſt laid aſide his breaſtplate and embroidered ephod, as being a day of humiliation. He firſt offered a bullock and a ram for his own ſins, and thoſe of the prieſts; then he received from the heads of the people two goats for a ſin offering, and a ram for a burnt offering, to be offered in the name of the whole multitude. It was determined by lot which of the goats ſhould be ſacrificed, and which ſet at liberty. After this he perfumed the ſanctuary with incenſe, and ſprinkled it with blood: then, coming out, he ſacrificed the goat upon which the lot had fallen. This done, the goat which was to be ſet at liberty being brought to him, he laid his hands upon its head, confeſſed his ſins and the ſins of the people, and then ſent it away into ſome deſert place: it was called azazel, or the ſcape-goat. As to the expiations among the heathens, they were of ſeveral kinds; as ſacrifices, and religious waſhings.

EXPIATION, in a figurative ſenſe, is applied by divines to the pardon procured to mens ſins, by the merits of Chriſt's death.

EXPIRATION, in medicine, that motion in an animal whereby the air inſpired into the lungs is expelled or thrown out of the ſame, and the cavity of the breaſt contracted. Reſpiration conſiſts of two alternate motions or actions of the lungs, correſponding to thoſe of a pair of bellows: inſpiration, whereby the air is drawn in; and expiration, whereby it is driven out again. By the means of this alteration, the circulation of the blood, and the motion of the heart, are maintained. Expiration is alſo uſed figuratively, for the end of a term of time granted, agreed on, or adjudged.

EXPLICIT, ſomething clear, diſtinct, formal and unfolded. The will or intention is ſaid to be explicit when it is fully explained in proper terms; and implicit, when it is only to be learnt by deductions and conſequences. The Jews had not all an explicit knowledge of Jeſus Chriſt, but they had at leaſt an implicit one. Such a teſtator has declared his will explicitly, i. e. in formal terms; there is no need to have recourſe to explications.

EXPLOSION, from *explodo, I drive away with noiſe*, in phyſics, the act of a thing which drives another away out of the place it before poſſeſſed. The term is chiefly uſed for the going off of gunpowder, and the expulſion of the ball, ſhot, or the like conſequent thereon. Hence, exploſion comes likewiſe to be figuratively uſed to expreſs ſuch ſudden actions of bodies as have ſome reſemblance to theſe; e. gr. thoſe which ferment with violence, immediately upon their mixture, and occaſion a crackling ſound.

EXPONENT, in algebra, the ſame with index. See the definition in Syſtem of ALGEBRA, Sect. I.

EXPONENT is alſo uſed in arithmetic in the ſame ſenſe as index or logarithm.

EXPORTATION, in commerce, the act of ſending commodities out of one country into another. Exportation is a part of foreign commerce, diſtinguiſhed by the appellation *active*, or *ſelling part*, in oppoſition to importation, which is called the *paſſive*, or *buying part*. It is obſerved, as a general maxim, that commerce, when active, muſt produce a flow of riches, the balance being received in money; whereas, if it be paſſive, treaſures will be exhauſted, as the balance of trade muſt continually be made good out of the remaining coin. Hence plenty of money in any place implies, that the quantity of goods exported far exceeds that of goods imported: and wherever money is ſcarce, it may be concluded, that greater quantities of goods have been imported than exported. See EXCHANGE. The merchandiſes yearly exported from England are immenſe. The principal articles are corn, cattle, cloth, iron, lead, tin, leather, coal, hops, flax, hemp, hats, malt liquors, fiſh, watches, ribbands, &c.

EXPOSING, the act of ſetting a thing to public view. In the Romiſh church, the ſacrament is ſaid to be expoſed when it is ſhewn in public, uncovered, on feſtival days, and during the time of plenary indulgences. Expoſing is alſo uſed with farther latitude; thus, we ſay, it is prohibited to expoſe falſe and clipped money. Such a houſe ſtands very high, and has a delicious proſpect; but it is expoſed to all the four winds. Such a city being on the frontiers, and not fortified, is expoſed to the inſults of every party of forces.

EXPOSITION, in a literary ſenſe, the explaining an author, paſſage, writing, or the like, and ſetting their meaning in an obvious and clear light. Such is Bankes's Expoſition and Commentary on the Holy Bible, wherein all the difficult paſſages are fully explained and illuſtrated.

EXPOSITOR, or EXPOSITORY, a title given to ſmall dictionaries, ſerving to explain the hard words of a language.

EXPOSTULATION, in rhetoric, a warm addreſs to a perſon, who has done another ſome injury, repreſenting the wrong in the ſtrongeſt terms, and demanding redreſs.

EXPOSURE, in gardening, the ſituation of a garden-wall, or the like, with reſpect to the points of the compaſs, as ſouth or eaſt. See GARDENING.

EXPRESS, ſomething that is preciſe, in formal terms, or for ſome particular deſign. I told him as much in expreſs terms: he gave me a commiſſion expreſs; he had expreſs orders; a courier was diſpatched expreſs. We alſo ſay, ſomewhat abuſively, to ſend an expreſs, meaning a courier.

EXPRESSED *Oils*, are ſuch as are procured from bodies only by preſſing: as the oils of olives, almonds, and the like.

EXPRESSION, in reading. See READING.

EXPRESSION, in muſic, denotes the performing of a piece of melody, or a ſingle paſſage, with that energy and feeling which the poetry or paſſion to be impreſſed upon the hearer requires.

EXPRESSION, in oratory, denotes the manner of delivering or conveying a man's ideas to another. Expreſſion is more particularly uſed for the elocution, diction, and choice of words in a diſcourſe. See LANGUAGE and ORATORY.

It is not enough that a poet or orator have fine thoughts, he muſt likewiſe have a happy expreſſion. Defects in the expreſſion ordinarily ariſe from defects in the imagination; abundance of the beauties of the ancient writers are annexed either to expreſſions which are peculiar to their language: or to relations, which, not being ſo familiar to us as to them, do not give us the ſame pleaſure.

Expreſſion, in drawing and painting, denotes a natural and lively repreſentation of the ſubject, or of the ſeveral objects intended to be ſhewn. The expreſſion conſiſts principally in repreſenting the human body and all its parts in the action ſuitable to it, in exhibiting in the face the ſeveral paſſions proper to the figures, and obſerving the motions they impreſs on the other external parts. The term expreſſion is ordinarily confounded with that of paſſion; but they differ in this, that expreſſion is a general term, implying a repreſentation of an object, agreeably to its nature and character, and the uſe or office it is to have in the work; whereas paſſion, in painting, denotes a motion of the body, accompanied with certain diſpoſitions or airs of the face, which mark an agitation in the ſoul. So that every paſſion is an expreſſion, but not every expreſſion a paſſion. See Treatiſe on the Art of Drawing, Sect. VII.

EXPULSION, the act of driving a man by force out of a city, community, or the like.

Expulsion is alſo uſed in medicine, for the act of driving out a foreign body with violence from the place it was in. The uterus has the chief office in the expulſion of the fœtus; if the expulſion of the fœtus happen very ſoon after conception, it is called a falſe birth.

EXSICCATION, formed of *ex* and *ſiccus*, *dry*, in chymiſtry, &c. the act of drying up or evaporating the moiſture of a thing.

EXTACY, a tranſport which ſuſpends the function of the ſenſes, by the intenſe contemplation of ſome extraordinary or ſupernatural object. Extacy, in medicine, a ſpecies of catelepſy, when a perſon perfectly remembers, after the paroxyſm is over, the ideas he conceived during the time it laſted.

EXTANT, ſomething that ſtill ſubſiſts, or is in being. It is but part of the Hiſtory of Livy, of the writings of Cicero, Cæſar, &c. that are extant, the reſt are loſt. We have nothing extant, of Socrates, though he wrote a great deal.

EXTENSION, in philoſophy, one of the common and eſſential properties of body; or that by which it poſſeſſes or takes up ſome part of univerſal ſpace, which is called the place of that body. See Metaphysics.

EXTENSOR, in anatomy, a name common to ſeveral muſcles, ſerving to extend or ſtretch out the parts, and particularly the hands or feet. See Syſtem of Anatomy, Sections XIII. and XIV.

EXTENUATION, the act of diminiſhing or leſſening the bulk or ſubſtance of a thing, eſpecially of the human body. Fevers, agues, long abſtinences, &c. occaſion great extenuations or emaciations.

EXTERMINATION, formed of *ex* and *terminus*, *boundary*, the act of extirpating, or totally deſtroying a people, race, family, &c. The Jews have been exterminated out of Portugal, the Moors out of Spain, the Albigenſes out of France, &c. Philip the Fair of France, to be revenged on the knights templars, took a reſolution in 1307 to exterminate them.

Extermination, or **Exterminating**, in algebra, is uſed for taking away. Thus algebraiſts ſpeak of exterminating ſurds, fractions, and unknown quantities out of equations. See Syſtem of Algebra, Sect. V. Article XIX.

EXTERNAL, or **Exterior**, a term of relation, applied to the ſurface or out ſide of a body; or that part which appears or preſents itſelf to the eye, touch, &c. In which ſenſe it is oppoſed to internal or interior. The ſenſes are divided into external, which are thoſe whereby we perceive ideas, or have the perception of external objects; as ſeeing, hearing, &c. and internal.

External is alſo uſed to expreſs any thing that is withoutſide a man, or that is not within him, and particularly in his mind. In which ſenſe, we ſay external objects, &c.

EXTINCTION, the act of extinguiſhing, that is, of putting out or deſtroying fire, flame, or light.

Extinction, in chymiſtry and pharmacy, is when a metal, mineral, or the like body, after having been heated red hot in the fire, is plunged in ſome fluid; either to ſoften or temper its acrimony, as tutty in roſe water; or to communicate its virtue to the liquor, as iron or ſteel to common water; or, laſtly, to give it a temper, as in the extinction of ſteel in water, or ſome other preparation.

EXTIRPATION, formed of *ex* and *ſtirps*, *root*, the act of pulling up, or deſtroying, a thing to the very roots.

Extirpation is alſo uſed, in ſurgery, for cutting off any part entirely; as a wen, &c. or the eating it away, as a wart, &c. by corroſive medicines.

EXTORTION, in law, an illegal manner of wreſting any thing from a man, either by force, menace, or authority. If an officer, by terrifying another, on pretence of his office, takes more than his ordinary fees, or dues, he commits, and is indictable for extortion. So the exacting of unlawful uſury, winning by unlawful game, and, in fine, all taking of more than is juſtly due, by colour or pretence of right, as exceſſive tolls in millers, exceſſive prices of ale, bread, victuals, wares, &c. come under extortion.

EXTRA *Judicial*, ſomething done out of the proper court, or the ordinary courſe of law. As when judgment is given in a cauſe, or caſe, not depending in that court where ſuch judgment is given, or wherein the judge has no juriſdiction.

Extra *Parochial*, a place out of the bounds of any pariſh; or privileged and freed from the duties of a pariſh.

EXTRACT, **Extractum**, in pharmacy, the pureſt and fineſt part of a vegetable, or other body, ſeparated from the coarſer, by diſſolution and digeſtion with a proper menſtruum; and afterwards reduced into a thick, moiſt conſiſtence by diſtillation, or evaporation of the humidity of the menſtruum. Extracts are prepared from a variety of different drugs; as the bark, gentian, jalap, opium, &c.

Extract, in matters of literature, denotes a ſhort abridgment of a book or paper, or of ſome of the matters thereof. The journals, nouvalles, bibliotheques, memoires, and other monthly reviews, or quarterly accounts of the affairs of learning, conſiſt principally of extracts of the moſt material paſſages, doctrines, &c. found in the ſeveral books publiſhed in that time.

EXTRACTION, in pharmacy and chymiſtry, an operation, whereby eſſences, tinctures, &c. are drawn from natural bodies.

Extraction, in ſurgery, denotes an operation whereby ſome foreign matter lodged in the body, contrary to the order of nature, is drawn out of the ſame by manual application, or the help of inſtruments. Such is the extraction of a ſtone, formed in the bladder, or in the kidneys, &c.

Extraction, or *Deſcent*, in genealogy, denotes the ſtock, or family which a perſon is deſcended from. In ſome military orders, chapters, &c. a candidate muſt make proof of the nobility of his extraction before he is admitted.

Extraction *of Roots*, the method of finding the roots of given numbers, or quantities. The ſquare, cube, and other powers of a number, or root, are formed by multiplying the given number into itſelf a greater or leſs number of times, as the power required is higher or lower. See Syſtem of Arithmetic. Article XII.

EXTRACTOR, in midwifry, an inſtrument contrived to extract children in caſes of difficult births. See Syſtem of Midwifry.

EXTRAORDINARY, ſomething out of the common courſe. Extraordinary couriers, are thoſe ſent expreſs on ſome urgent occaſion. Extraordinary ambaſſador, or envoy, is ſuch a one as is ſent to treat or negotiate ſome ſpecial and important affair, as a marriage, a treaty, confederacy, &c. or even on occaſion of ſome ceremony, as condolence, congratulation, &c. A gazette, journal, or other news paper extraordinary, is that publiſhed after ſome great and notable event, containing the detail or particulars thereof, which are not found in the ordinary papers. Our news writers generally uſe poſtſcripts, or ſupplements, inſtead of extraordinaries.

EXTRAVASATION, in contuſions, fiſſures, depreſſions, fractures, and other accidents of the cranium, is when one or more of the blood veſſels, that are diſtributed in the dura mater, is broke or divided, whereby there is ſuch a diſcharge of blood as greatly oppreſſes the brain, and diſturbs its office; frequently bringing on violent pains, and other miſchiefs; and at length death itſelf, unleſs the patient is timely relieved.

Extravasation is ſometimes likewiſe uſed in ſpeaking of other humours beſide the blood; as the lympha, urine, &c. The gardeners uſe the term in ſpeaking of gums, juices, &c. which ouſe out of their trees either ſpontaneouſly, or at inciſions.

EXTRAVERSIO, in chymiſtry, a term uſed to expreſs the rendering manifeſt any thing ſaline, alkaline, or acid, concealed in mixed bodies; and is juſt the reverſe to one of the ſpecies of concentration, which hides theſe qualities.

EXTREAM, or **Extreme**, is applied to the laſt and outermoſt part of any thing; or that which finiſhes and terminates it on that ſide. The extreams of a line are points. There is no paſſing out of one extream into the other, without going through the middle. Extream remedies muſt only be had recourſe to in extream neceſſity. Anatomiſts apply the denomination extremes, or extremities, to the arms and legs.

Extreams, in logic, denote the two extream terms of the concluſion of a ſyllogiſm; viz. the predicate and ſubject. They are called extreams, from their relation to another term, which is a medium or mean between them.

Extream *Unction*, one of the ſacraments of the Romiſh church, the fifth in order, adminiſtered to people dangerouſly ſick, by anointing them with holy oils, and pronouncing ſeveral prayers over them. It is called extream unction, as being only given to perſons in extremity.

EXTREMITIES *of Figures*, in painting, is uſed for the head, hands, and feet. Theſe ſhould be drawn with more niceneſs and exactneſs, or more terminated than other parts; and thus help to render the action more expreſſive.

EXTRINSIC is applied in various ſenſes. Sometimes it ſignifies a thing's not belonging to the eſſence of another; in which ſenſe, the efficient cauſe, and the end, or ſcope of a thing, are ſaid to be extrinſic, or extrinſic cauſes. Sometimes it implies a thing not being contained within the capacity of another. In which ſenſe, thoſe cauſes are ſaid to be intrinſic, which introduce ſomething into a ſubject from without: as when fire introduces heat, &c. Sometimes it denotes a thing added, or applied to another. Thus, accidents and adherences are ſaid to be extrinſic to the ſubject; and thus viſion is extrinſic to the object ſeen.

EXTUBERANCES, in medicine, are ſwellings forth, or riſings up in the fleſh, or other parts of the body.

EXUDATION, the act of ſweating out. In which manner, gums, balſams, &c. are uſually produced from trees.

EXULCERATION, in medicine, the act of cauſing, or producing ulcers. Thus, arſenic exulcerates the inteſtines; corroſive humours exulcerate the ſkin.

Exulceration is ſometimes alſo uſed for an ulcer itſelf; but, more generally, for thoſe beginning eroſions which wear away the ſubſtance, and form ulcers. Exulcerations in the inteſtines are marks of poiſon.

EXUVIÆ, formed from *exuere, to put off, to diveſt*, in phyſiology, tranſient parts of certain animals, which they put off, or lay down, and aſſume new ones. Such, eſpecially, are the ſkins, or ſloughs of ſerpents; ſhells of lobſters, and the like; which are annually changed, and renewed in the ſpring.

The outer integument of the body, which in man and other large animals is ſo durably fixed on the body, is in many of the animals of the reptile kind much more looſely fixed, and is changeable ſeveral times during the period of their lives. The ſerpent-kind all ſhift their ſkins ſeveral times in their lives, and the water-newt has been lately obſerved to do the ſame: but no creature in the world does it ſo often as the caterpillar, almoſt every ſpecies of theſe inſects throwing off their old ſkin once in ten or twelve days, or leſs; and this in ſuch a manner as is extremely worthy an attentive obſervation. See Caterpiller.

Exuviæ is alſo uſed for ſome ſhells, and other marine bodies, frequently found in the bowels of the earth; ſuppoſed to have been depoſited there at the deluge, as being the real ſpoils of once living creatures. See Shell, Fossil, and Deluge.

EYE, the organ, or part, of the body, whereby a viſion is effected; i. e. whereby viſible objects are repreſented to the mind. For a full deſcription of the ſeveral parts, ſee Syſtem of Anatomy, Part VI. Sect. XI. For the repreſentation, ſee Plate XI.

EYRE, or Eire, in law, ſignifies the court of juſtices itinerant. The word ſeems formed of the old French *irre, iter, way or track*. Hence juſtices in *eyre*, are thoſe whom Bracton calls *juſticiarii itinerantes*.

Eyre *of the Foreſt*, is otherwiſe called *juſtice-ſeat*, which by the ancient cuſtoms was to be held every three years by the juſtice of the foreſt, journeying up and down for that purpoſe.

EZEKIEL, a canonical book of the Old Teſtament, referring chiefly to the degenerate manner and corruptions of the Jews in the times when the author wrote. It abounds with fine ſentiments and rich compariſons, and diſcovers much learning in profane matters. Ezekiel was carried captive to Babylon with Jechoniah or Jehoiachin, and began his prophecies in the fifth year of the captivity, or in the year before Chriſt 595. He was contemporary with Jeremiah, who propheſied at the ſame time in Judea. He foretold many events, particularly the deſtruction of the temple, the fatal cataſtrophe of thoſe who revolted from Babylon to Egypt, and the happy return of the Jews to their own land.

EZRA, or Ezdras, in divinity. The Book of Ezra is a book of Holy Scripture, compoſed in Hebrew by Ezra or Ezdras, the high prieſt of the Jews during the captivity; and particularly about the time when they returned to Paleſtine, under the reign of Cyrus. This Book contains the hiſtory of the Jews from the time of Cyrus's edict for their return, to the twentieth year of Artaxerxes Longimanus. It ſpecifies the number of Jews who returned, and Cyrus's proclamation for rebuilding the temple, the obſtruction it met with, and the finiſhing thereof in the reign of Darius. It is canonical, and allowed as ſuch both by the church and the ſynagogue. The books of Ezra, called in the Engliſh verſion the Firſt and Second Books of Eſdras, though held by ſome, particularly the Greeks, for canonical, are thrown by the Engliſh church into the number of apocryphal books, being only extant in Greek. The Canon of Ezra is the collection of the books of the Scripture made by that pontiff. It appears, however, that the ſynagogue added other books to Ezra's canon; witneſs the book of Ezra itſelf, that of Nehemiah, and ſeveral others.

F

F, THE fourth conſonant, and ſixth letter of the alphabet. The letter F is borrowed from the digamma or double gamma of the Ælians, as is evident from the inſcription on the pedeſtal of the Coloſſus at Delos; and was undoubtedly formed from the old Hebrew vau: and though this letter is not found in the modern Greek alphabet, yet it was in the ancient one, from whence the Latins received it, and tranſmitted it to us.

It is formed by a ſtrong expreſſion of the breath, and joining at the ſame time the upper teeth and under lip. It has but one ſort of ſound, which has a great affinity with *v* and *ph*, the latter being written for it by us in all Greek words, as philoſophy, &c. though the Italians write it *filoſofia*.

F, in phyſical preſcriptions ſtands for *fiat*, or "Let it be done." Thus *f. s. a.* ſignifies *fiat ſecundum artem*. F was alſo a numeral letter, ſignifying 404.

FABLE, a tale, or feigned narration, deſigned either to inſtruct or divert, diſguiſed under the allegory of an action, &c. Fables were the firſt pieces of wit that made their appearance in the world; and have continued to be highly valued, not only in times of the greateſt ſimplicity, but in the moſt polite ages of the world. Jotham's fable of the trees is the oldeſt that is extant, and as beautiful as any that have been made ſince. Nathan's fable of the poor man is next in antiquity. We find Æſop in the moſt diſtant ages of Greece; and in the early days of the Roman commonwealth, we read of a mutiny appeaſed by the fable of the belly and the members. As fables had their riſe in the very infancy of learning, they never flouriſhed more than when learning was at its greateſt height.

Fable is the fineſt way of giving counſel, and moſt univerſally pleaſing, becauſe leaſt ſhocking; for, in the reading of a fable, a man thinks he is directing himſelf, whilſt he is following the dictates of another, and conſequently is not ſenſible of that which is the moſt unpleaſing circumſtance in advice. Beſides, the mind is never ſo much pleaſed as when ſhe exerts herſelf in any action that gives her an idea of her own abilities; this natural pride of the ſoul is very much gratified in the reading of fable.

Fable is alſo uſed for the plot of an epic or dramatic poem; and is, according to Ariſtotle, the principal part, and, as it were, the ſoul of the poem.

There are two reaſons why fables have pleaſed in all ages and places. The firſt is, that ſelf-love is ſpared in the inſtruction. The ſecond, that the mind is exerciſed by the allegory. Men do not love direct precepts; too proud to condeſcend to thoſe philoſophers who ſeem to command what they teach, they require to be inſtructed in a more humble manner; they would never amend, if they thought that to amend were to obey: add, that there is a ſort of activity in the mind which muſt be humoured: it pleaſes itſelf in a penetration which diſcovers more than is ſhewn; and in apprehending what is hid under a veil, fancies itſelf in ſome meaſure the author of it.

The truth or idea intended ſhould ariſe in the readers mind from the fable itſelf. However, for the conveniency of the leſs diſcerning readers, it may be a good way to point out the truth or moral in preciſer terms. To have the moral at the end of the fable ſeems much better than at the beginning: the mind is apt to be fore-ſtalled in the latter caſe; I carry the key along with me, ſo that there is no room to exerciſe my mind in finding any thing myſelf.

The writers of fables are not many. If there were any before Æſop, who lived in the time of Solon, about the fifty ſecond Olympiad, his ſucceſs has quite effaced their memory; and even occaſioned all the good things of that kind to be aſcribed to him.

Among the moderns, the moſt celebrated writers are Meſſ. de la Fontaine and De la Motte: the firſt of whom has picked out all the beſt things in Æſop, Phædrus, and Pilpa, and given them anew in French, with a delicacy and ſimplicity peculiar to himſelf; and which in the judgment of his countrymen, ſets him even above Phædrus. The latter, rather than content himſelf with what De la Fontaine had left, choſe to be an inventor. He has ſucceeded. His fables are many of them very happy, though ſome think them too full of thought and reaſoning. His verſification is infinitely more correct than that of La Fontaine, and more ſuitable to the ſubject than that of Le Noble. We have likewiſe ſome fables much eſteemed of Mr. Gay, and Mr. Moore.

Fable is alſo uſed for the plot of an epic or dramatic poem, or the action which makes the ſubject of ſuch a poem or romance. The fable, according to Ariſtotle, is the principal part, and as it were the ſoul of a poem. It muſt be conſidered as the firſt foundation of the compoſition, or the principle which gives life and motion to all the parts. In this ſenſe the fable is defined, "A diſcourſe invented with art, to form the manners by inſtructions diſguiſed under the allegory of an action."

The fable, according to Ariſtotle, conſiſts of two eſſential parts, viz. truth as its foundation; and fiction, which diſguiſes the truth, and gives it the form of fable. The truth is the point of morality intended to be inculcated; the fiction is the action, or words the inſtruction is covered under.

FABRIC, in general, denotes the ſtructure or conſtruction of any thing; but particularly of buildings, as a church, hall, houſe, &c. See Syſtem of Architecture on the Principles of the Art.

FACE, the ſurface, or firſt ſide which a body preſents to the eye; ſee Surface. We ſay, the face of the earth, of the waters, &c. Polyhedrons have ſeveral faces; ſee Polyhedron. A die, or cube, has ſix faces; ſee Cube.

Face is particularly uſed for the viſage of an animal, and

Expression, in drawing and painting, denotes a natural and lively repreſentation of the ſubject, or of the ſeveral objects intended to be ſhewn. The expreſſion conſiſts principally in repreſenting the human body and all its parts in the action ſuitable to it, in exhibiting in the face the ſeveral paſſions proper to the figures, and obſerving the motions they impreſs on the other external parts. The term expreſſion is ordinarily confounded with that of paſſion; but they differ in this, that expreſſion is a general term, implying a repreſentation of an object, agreeably to its nature and character, and the uſe or office it is to have in the work; whereas paſſion, in painting, denotes a motion of the body, accompanied with certain diſpoſitions or airs of the face, which mark an agitation in the ſoul. So that every paſſion is an expreſſion, but not every expreſſion a paſſion. See Treatiſe on the Art of Drawing, Sect. VII.

EXPULSION, the act of driving a man by force out of a city, community, or the like.

Expulsion is alſo uſed in medicine, for the act of driving out a foreign body with violence from the place it was in. The uterus has the chief office in the expulſion of the fœtus; if the expulſion of the fœtus happen very ſoon after conception, it is called a falſe birth.

EXSICCATION, formed of *ex* and *ſiccus, dry*, in chymiſtry, &c. the act of drying up or evaporating the moiſture of a thing.

EXTACY, a tranſport which ſuſpends the function of the ſenſes, by the intenſe contemplation of ſome extraordinary or ſupernatural object. Extacy, in medicine, a ſpecies of catelepſy, when a perſon perfectly remembers, after the paroxyſm is over, the ideas he conceived during the time it laſted.

EXTANT, ſomething that ſtill ſubſiſts, or is in being. It is but part of the Hiſtory of Livy, of the writings of Cicero, Cæſar, &c. that are extant, the reſt are loſt. We have nothing extant, of Socrates, though he wrote a great deal.

EXTENSION, in philoſophy, one of the common and eſſential properties of body; or that by which it poſſeſſes or takes up ſome part of univerſal ſpace, which is called the place of that body. See Metaphysics.

EXTENSOR, in anatomy, a name common to ſeveral muſcles, ſerving to extend or ſtretch out the parts, and particularly the hands or feet. See Syſtem of Anatomy, Sections XIII. and XIV.

EXTENUATION, the act of diminiſhing or leſſening the bulk or ſubſtance of a thing, eſpecially of the human body. Fevers, agues, long abſtinences, &c. occaſion great extenuations or emaciations.

EXTERMINATION, formed of *ex* and *terminus, boundary*, the act of extirpating, or totally deſtroying a people, race, family, &c. The Jews have been exterminated out of Portugal, the Moors out of Spain, the Albigenſes out of France, &c. Philip the Fair of France, to be revenged on the knights templars, took a reſolution in 1307 to exterminate them.

Extermination, or Exterminating, in algebra, is uſed for taking away. Thus algebraiſts ſpeak of exterminating ſurds, fractions, and unknown quantities out of equations. See Syſtem of Algebra, Sect. V. Article XIX.

EXTERNAL, or Exterior, a term of relation, applied to the ſurface or out ſide of a body; or that part which appears or preſents itſelf to the eye, touch, &c. In which ſenſe it is oppoſed to internal or interior. The ſenſes are divided into external, which are thoſe whereby we perceive ideas, or have the perception of external objects; as ſeeing, hearing, &c. and internal.

External is alſo uſed to expreſs any thing that is withoutſide a man, or that is not within him, and particularly in his mind. In which ſenſe, we ſay external objects, &c.

EXTINCTION, the act of extinguiſhing, that is, of putting out or deſtroying fire, flame, or light.

Extinction, in chymiſtry and pharmacy, is when a metal, mineral, or the like body, after having been heated red hot in the fire, is plunged in ſome fluid; either to ſoften or temper its acrimony, as tutty in roſe water; or to communicate its virtue to the liquor, as iron or ſteel to common water; or, laſtly, to give it a temper, as in the extinction of ſteel in water, or ſome other preparation.

EXTIRPATION, formed of *ex* and *ſtirps, root*, the act of pulling up, or deſtroying, a thing to the very roots.

Extirpation is alſo uſed, in ſurgery, for cutting off any part entirely; as a wen, &c. or the eating it away, as a wart, &c. by corroſive medicines.

EXTORTION, in law, an illegal manner of wreſting any thing from a man, either by force, menace, or authority. If an officer, by terrifying another, on pretence of his office, takes more than his ordinary fees, or dues, he commits, and is indictable for extortion. So the exacting of unlawful uſury, winning by unlawful game, and, in fine, all taking of more than is juſtly due, by colour or pretence of right, as exceſſive tolls in millers, exceſſive prices of ale, bread, victuals, wares, &c. come under extortion.

EXTRA *Judicial*, ſomething done out of the proper court, or the ordinary courſe of law. As when judgment is given in a cauſe, or caſe, not depending in that court where ſuch judgment is given, or wherein the judge has no juriſdiction.

Extra *Parochial*, a place out of the bounds of any pariſh; or privileged and freed from the duties of a pariſh.

EXTRACT, Extractum, in pharmacy, the pureſt and fineſt part of a vegetable, or other body, ſeparated from the coarſer, by diſſolution and digeſtion with a proper menſtruum; and afterwards reduced into a thick, moiſt conſiſtence by diſtillation, or evaporation of the humidity of the menſtruum. Extracts are prepared from a variety of different drugs; as the bark, gentian, jalap, opium, &c.

Extract, in matters of literature, denotes a ſhort abridgment of a book or paper, or of ſome of the matters thereof. The journals, nouvalles, bibliotheques, memoires, and other monthly reviews, or quarterly accounts of the affairs of learning, conſiſt principally of extracts of the moſt material paſſages, doctrines, &c. found in the ſeveral books publiſhed in that time.

EXTRACTION, in pharmacy and chymiſtry, an operation, whereby eſſences, tinctures, &c. are drawn from natural bodies.

Extraction, in ſurgery, denotes an operation whereby ſome foreign matter lodged in the body, contrary to the order of nature, is drawn out of the ſame by manual application, or the help of inſtruments. Such is the extraction of a ſtone, formed in the bladder, or in the kidneys, &c.

Extraction, or *Deſcent*, in genealogy, denotes the ſtock, or family which a perſon is deſcended from. In ſome military orders, chapters, &c. a candidate muſt make proof of the nobility of his extraction before he is admitted.

Extraction *of Roots*, the method of finding the roots of given numbers, or quantities. The ſquare, cube, and other powers of a number, or root, are formed by multiplying the given number into itſelf a greater or leſs number of times, as the power required is higher or lower. See Syſtem of Arithmetic. Article XII.

EXTRACTOR, in midwifry, an inſtrument contrived to extract children in caſes of difficult births. See Syſtem of Midwifry.

EXTRAORDINARY, ſomething out of the common courſe. Extraordinary couriers, are thoſe ſent expreſs on ſome urgent occaſion. Extraordinary ambaſſador, or envoy, is ſuch a one as is ſent to treat or negotiate ſome ſpecial and important affair, as a marriage, a treaty, confederacy, &c. or even on occaſion of ſome ceremony, as condolence, congratulation, &c. A gazette, journal, or other news paper extraordinary, is that publiſhed after ſome great and notable event, containing the detail or particulars thereof, which are not found in the ordinary papers. Our news writers generally uſe poſtſcripts, or ſupplements, inſtead of extraordinaries.

EXTRAVASATION, in contuſions, fiſſures, depreſſions, fractures, and other accidents of the cranium, is when one or more of the blood veſſels, that are diſtributed in the dura mater, is broke or divided, whereby there is ſuch a diſcharge of blood as greatly oppreſſes the brain, and diſturbs its office; frequently bringing on violent pains, and other miſchiefs; and at length death itſelf, unleſs the patient is timely relieved.

Extravasation is ſometimes likewiſe uſed in ſpeaking of other humours beſide the blood; as the lympha, urine, &c. The gardeners uſe the term in ſpeaking of gums, juices, &c. which ouſe out of their trees either ſpontaneouſly, or at inciſions.

EXTRAVERSIO, in chymiſtry, a term uſed to expreſs the rendering manifeſt any thing ſaline, alkaline, or acid, concealed in mixed bodies; and is juſt the reverſe to one of the ſpecies of concentration, which hides theſe qualities.

EXTREAM, or Extreme, is applied to the laſt and outermoſt part of any thing; or that which finiſhes and terminates it on that ſide. The extreams of a line are points. There is no paſſing out of one extream into the other, without going through the middle. Extream remedies muſt only be had recourſe to in extream neceſſity. Anatomiſts apply the denomination extremes, or extremities, to the arms and legs.

Extreams, in logic, denote the two extream terms of the concluſion of a ſyllogiſm; viz. the predicate and ſubject. They are called extreams, from their relation to another term, which is a medium or mean between them.

Extream *Unction*, one of the ſacraments of the Romiſh church, the fifth in order, adminiſtered to people dangerouſly ſick, by anointing them with holy oils, and pronouncing ſeveral prayers over them. It is called extream unction, as being only given to perſons in extremity.

EXTREMITIES *of Figures*, in painting, is uſed for the head, hands, and feet. Theſe ſhould be drawn with more niceneſs and exactneſs, or more terminated than other parts; and thus help to render the action more expreſſive.

EXTRINSIC is applied in various ſenſes. Sometimes it ſignifies a thing's not belonging to the eſſence of another; in which ſenſe, the efficient cauſe, and the end, or ſcope of a thing, are ſaid to be extrinſic, or extrinſic cauſes. Sometimes it implies a thing not being contained within the capacity of another. In which ſenſe, thoſe cauſes are ſaid to be intrinſic, which introduce ſomething into a ſubject from without: as when fire introduces heat, &c. Sometimes it denotes a thing added, or applied to another. Thus, accidents and adherences are ſaid to be extrinſic to the ſubject; and thus viſion is extrinſic to the object ſeen.

EXTUBERANCES, in medicine, are ſwellings forth, or riſings up in the fleſh, or other parts of the body.

EXUDATION, the act of ſweating out. In which manner, gums, balſams, &c. are uſually produced from trees.

EXULCERATION, in medicine, the act of cauſing, or producing ulcers. Thus, arſenic exulcerates the inteſtines; corroſive humours exulcerate the ſkin.

EXULCERATION is ſometimes alſo uſed for an ulcer itſelf; but, more generally, for thoſe beginning eroſions which wear away the ſubſtance, and form ulcers. Exulcerations in the inteſtines are marks of poiſon.

EXUVIÆ, formed from *exuere, to put off, to diveſt*, in phyſiology, tranſient parts of certain animals, which they put off, or lay down, and aſſume new ones. Such, eſpecially, are the ſkins, or ſloughs of ſerpents; ſhells of lobſters, and the like; which are annually changed, and renewed in the ſpring.

The outer integument of the body, which in man and other large animals is ſo durably fixed on the body, is in many of the animals of the reptile kind much more looſely fixed, and is changeable ſeveral times during the period of their lives. The ſerpent-kind all ſhift their ſkins ſeveral times in their lives, and the water-newt has been lately obſerved to do the ſame: but no creature in the world does it ſo often as the caterpillar, almoſt every ſpecies of theſe inſects throwing off their old ſkin once in ten or twelve days, or leſs; and this in ſuch a manner as is extremely worthy an attentive obſervation. See CATERPILLER.

EXUVIÆ is alſo uſed for ſome ſhells, and other marine bodies, frequently found in the bowels of the earth; ſuppoſed to have been depoſited there at the deluge, as being the real ſpoils of once living creatures. See SHELL, FOSSIL, and DELUGE.

EYE, the organ, or part, of the body, whereby a viſion is effected; i. e. whereby viſible objects are repreſented to the mind. For a full deſcription of the ſeveral parts, ſee Syſtem of ANATOMY, Part VI. Sect. XI. For the repreſentation, ſee Plate XI.

EYRE, or **EIRE**, in law, ſignifies the court of juſtices itinerant. The word ſeems formed of the old French *irre, iter, way or track.* Hence juſtices in *eyre*, are thoſe whom Bracton calls *juſticiarii itinerantes.*

EYRE *of the Foreſt*, is otherwiſe called *juſtice-ſeat*, which by the ancient cuſtoms was to be held every three years by the juſtice of the foreſt, journeying up and down for that purpoſe.

EZEKIEL, a canonical book of the Old Teſtament, referring chiefly to the degenerate manner and corruptions of the Jews in the times when the author wrote. It abounds with fine ſentiments and rich compariſons, and diſcovers much learning in profane matters. Ezekiel was carried captive to Babylon with Jechoniah or Jehoiachin, and began his prophecies in the fifth year of the captivity, or in the year before Chriſt 595. He was contemporary with Jeremiah, who propheſied at the ſame time in Judea. He foretold many events, particularly the deſtruction of the temple, the fatal cataſtrophe of thoſe who revolted from Babylon to Egypt, and the happy return of the Jews to their own land.

EZRA, or **EZDRAS**, in divinity. The Book of Ezra is a book of Holy Scripture, compoſed in Hebrew by Ezra or Ezdras, the high prieſt of the Jews during the captivity; and particularly about the time when they returned to Paleſtine, under the reign of Cyrus. This Book contains the hiſtory of the Jews from the time of Cyrus's edict for their return, to the twentieth year of Artaxerxes Longimanus. It ſpecifies the number of Jews who returned, and Cyrus's proclamation for rebuilding the temple, the obſtruction it met with, and the finiſhing thereof in the reign of Darius. It is canonical, and allowed as ſuch both by the church and the ſynagogue. The books of Ezra, called in the Engliſh verſion the Firſt and Second Books of Eſdras, though held by ſome, particularly the Greeks, for canonical, are thrown by the Engliſh church into the number of apocryphal books, being only extant in Greek. The Canon of Ezra is the collection of the books of the Scripture made by that pontiff. It appears, however, that the ſynagogue added other books to Ezra's canon; witneſs the book of Ezra itſelf, that of Nehemiah, and ſeveral others.

F

F, THE fourth conſonant, and ſixth letter of the alphabet. The letter F is borrowed from the digamma or double gamma of the Ælians, as is evident from the inſcription on the pedeſtal of the Coloſſus at Delos; and was undoubtedly formed from the old Hebrew vau: and though this letter is not found in the modern Greek alphabet, yet it was in the ancient one, from whence the Latins received it, and tranſmitted it to us.

It is formed by a ſtrong expreſſion of the breath, and joining at the ſame time the upper teeth and under lip. It has but one ſort of ſound, which has a great affinity with *v* and *ph*, the latter being written for it by us in all Greek words, as philoſophy, &c. though the Italians write it *filoſofia*.

F, in phyſical preſcriptions ſtands for *fiat*, or "Let it be done." Thus *f. s. a.* ſignifies *fiat ſecundum artem*. F was alſo a numeral letter, ſignifying 404.

FABLE, a tale, or feigned narration, deſigned either to inſtruct or divert, diſguiſed under the allegory of an action, &c. Fables were the firſt pieces of wit that made their appearance in the world; and have continued to be highly valued, not only in times of the greateſt ſimplicity, but in the moſt polite ages of the world. Jotham's fable of the trees is the oldeſt that is extant, and as beautiful as any that have been made ſince. Nathan's fable of the poor man is next in antiquity. We find Æſop in the moſt diſtant ages of Greece; and in the early days of the Roman commonwealth, we read of a mutiny appeaſed by the fable of the belly and the members. As fables had their riſe in the very infancy of learning, they never flouriſhed more than when learning was at its greateſt height.

Fable is the fineſt way of giving counſel, and moſt univerſally pleaſing, becauſe leaſt ſhocking; for, in the reading of a fable, a man thinks he is directing himſelf, whilſt he is following the dictates of another, and conſequently is not ſenſible of that which is the moſt unpleaſing circumſtance in advice. Beſides, the mind is never ſo much pleaſed as when ſhe exerts herſelf in any action that gives her an idea of her own abilities; this natural pride of the ſoul is very much gratified in the reading of fable.

FABLE is alſo uſed for the plot of an epic or dramatic poem; and is, according to Ariſtotle, the principal part, and, as it were, the ſoul of the poem.

There are two reaſons why fables have pleaſed in all ages and places. The firſt is, that ſelf-love is ſpared in the inſtruction. The ſecond, that the mind is exerciſed by the allegory. Men do not love direct precepts; too proud to condeſcend to thoſe philoſophers who ſeem to command what they teach, they require to be inſtructed in a more humble manner; they would never amend, if they thought that to amend were to obey: add, that there is a ſort of activity in the mind which muſt be humoured: it pleaſes itſelf in a penetration which diſcovers more than is ſhewn; and in apprehending what is hid under a veil, fancies itſelf in ſome meaſure the author of it.

The truth or idea intended ſhould ariſe in the readers mind from the fable itſelf. However, for the conveniency of the leſs diſcerning readers, it may be a good way to point out the truth or moral in preciſer terms. To have the moral at the end of the fable ſeems much better than at the beginning: the mind is apt to be fore-ſtalled in the latter caſe; I carry the key along with me, ſo that there is no room to exerciſe my mind in finding any thing myſelf.

The writers of fables are not many. If there were any before Æſop, who lived in the time of Solon, about the fifty ſecond Olympiad, his ſucceſs has quite effaced their memory; and even occaſioned all the good things of that kind to be aſcribed to him.

Among the moderns, the moſt celebrated writers are Meſſ. de la Fontaine and De la Motte: the firſt of whom has picked out all the beſt things in Æſop, Phædrus, and Pilpa, and given them anew in French, with a delicacy and ſimplicity peculiar to himſelf; and which in the judgment of his countrymen, ſets him even above Phædrus. The latter, rather than content himſelf with what De la Fontaine had left, choſe to be an inventor. He has ſucceeded. His fables are many of them very happy, though ſome think them too full of thought and reaſoning. His verſification is infinitely more correct than that of La Fontaine, and more ſuitable to the ſubject than that of Le Noble. We have likewiſe ſome fables much eſteemed of Mr. Gay, and Mr. Moore.

FABLE is alſo uſed for the plot of an epic or dramatic poem, or the action which makes the ſubject of ſuch a poem or romance. The fable, according to Ariſtotle, is the principal part, and as it were the ſoul of a poem. It muſt be conſidered as the firſt foundation of the compoſition, or the principle which gives life and motion to all the parts. In this ſenſe the fable is defined, "A diſcourſe invented with art, to form the manners by inſtructions diſguiſed under the allegory of an action."

The fable, according to Ariſtotle, conſiſts of two eſſential parts, viz. truth as its foundation; and fiction, which diſguiſes the truth, and gives it the form of fable. The truth is the point of morality intended to be inculcated; the fiction is the action, or words the inſtruction is covered under.

FABRIC, in general, denotes the ſtructure or conſtruction of any thing; but particularly of buildings, as a church, hall, houſe, &c. See Syſtem of ARCHITECTURE on the Principles of the Art.

FACE, the ſurface, or firſt ſide which a body preſents to the eye; ſee SURFACE. We ſay, the face of the earth, of the waters, &c. Polyhedrons have ſeveral faces; ſee POLYHEDRON. A die, or cube, has ſix faces; ſee CUBE.

FACE is particularly uſed for the viſage of an animal, and eſpecially of man; and comprehends in the latter, all that part of the head which is not covered with the common long hair. The Latins call it *facies*, *vultus*, *os*, &c. The face, conſidered as the index of the paſſions, habits, &c. of the perſon, makes the ſubject of phyſiognomy. See PHYSIOGNOMY.

Anatomiſts uſually divide the face into two parts, the upper and lower: the upper is the front, or forehead; the lower includes the eyes, noſe, ears, mouth, and chin.

FACES *of Baſtion*, in fortification, are the two foremoſt ſides reaching from the flanks to the point of the baſtion where they meet. Theſe are commonly the firſt determinded, becauſe they reach fartheſt out, and are the leaſt flanked, and therefore weakeſt.

FACET, or **FACETTE**, a little face or ſide of a body, cut into a great number of angles. Multiplying glaſſes are cut in facets, or facet wiſe. Diamonds are alſo cut in facets or tables. In brilliants there are two ſorts, ſkew or ſkill facets, and ſtar facets. Skill facets are divided into upper and under. Upper ſkill facets are wrought on the lower part of the bezil, and terminate in the girdle. Under ſkill facets are wrought on the pavilions, and terminate in the girdle. Star facets are wrought on the upper part of the bezil, and terminate in the table. Jeffries on diamonds.

FACTION, a cabal or party formed in a ſtate to diſturb the public repoſe. The moſt celebrated factions are that of the Guelphs and Gibelins, who kept Italy in alarm for many ages; and with us that of the Whigs and Tories.

FACTOR, in commerce, an agent or perſon who acts and negociates for a merchant by commiſſion; called alſo commiſſioner, and on ſome occaſions broker, and throughout the Levant, coagis. Factors are either charged with the buying or the ſelling of goods, or with both. Thoſe of the firſt kind are uſually eſtabliſhed in places of conſiderable manufactories, or cities of great trade. Their office is to buy up commodities for merchants reſiding elſewhere; to ſee them packed, and ſend them to the perſons for whom they were bought. The duty of a factor is to procure the beſt intelligence of the ſtate of trade at his place of reſidence; of the courſe of exchange; of the quantity and quality of goods at market, their preſent price, and the probability that it may riſe or fall; to pay exact obedience to the orders of his employers; to conſult their advantage in matters referred to his direction; to execute their buſineſs with all the diſpatch that circumſtances admit; to be early in his intelligence, diſtinct in his accounts, and punctual in his correſpondence.

FACTORS *of Sale* are uſually fixed in places where there is a great trade. To theſe, merchants and manufacturers ſend their goods to be ſold for them according to the price and other conditions expreſſed in the orders delivered them. The wages or allowances for ſelling are uſually clear of all expences of carriage, exchange, remittances, &c. excepting poſtage of letters, which are never put to account. Factors ſhould ſtrictly obſerve the orders of their principals, or elſe they are liable to the damage accruing from the neglect of them. When factors have unlimited commiſſion to do for their conſtituents the beſt they can, they are excuſable, though their tranſactions are attended with loſs to their principals; but no factor, who has merely a commiſſion to ſell, &c. for another, is excuſable for entruſting another perſon beyond the uſual time allowed in the ſale of the commodities which he diſpoſes of: in ſuch a caſe he is anſwerable to the principal out of his own eſtate.

A factor that ſells a commodity under the price ordered by his principal ſhall be obliged to make good the difference; and if he purchaſes goods for another at a limited price, and they riſe in value, and he ſecures to himſelf the advantage, he is obliged to ſatisfy his principal for damages; or if he makes any advantage of the ſale of goods which his principal directed him to purchaſe, the principals ſhall recover it from him, and he is liable to be amerced for the fraud.

A factor who has money in hand belonging to his principals, and who neglects to inſure a ſhip and goods according to order, ſhall make good the damage if the ſhip miſcarry; and if he makes any compoſition with the inſurers after inſurance without orders, he is anſwerable for the whole inſurance. As fidelity and diligence are required from the factors, ſo the law requires the like from the principal: if, therefore, a perſon remits counterfeit jewels to his factor, who ſells them as true ones, and ſuſtains loſs or damage by impriſonment or other puniſhment, the principal ſhall not make ſatisfaction to the factor but to the party who purchaſed them. Buſineſs of this kind is called commiſſion-buſineſs; and traders in this way have current as well as commiſſion accounts conſtantly between them, and draw on, remit to, and ſend commiſſions to each other only by the intercourſe of letters, which among men of honour, are as obligatory and authoritative as all the bonds and ties of law.

FACTORAGE. The factorage or wages, called alſo commiſſion, is different at different places, and for different voyages; at a medium it may be fixed at about three per cent. of the value of the goods bought, beſide the charge of package, which is paid over and above. At Virginia, Barbadoes, and Jamaica, the factorage is about eight per cent. and the like throughout the greateſt part of the Weſt Indies. In Italy it is two and a half; in Holland one and a half; in Spain, Portugal, France, &c. it is two per cent.

FACTORY, a place where a conſiderable number of factors reſide to negociate and officiate for their maſters or principals. The term is chiefly uſed in ſpeaking of the Eaſt Indies, and other parts of Aſia, Turky, Italy, Portugal, &c. whither the European nations ſend their ſhips every year, and where they keep factors to buy the commodities of the country, and ſell thoſe brought from Europe. The moſt conſiderable factories belonging to the Britiſh are thoſe eſtabliſhed in the Eaſt-Indies, Portugal, Turky, &c.

FACULTY, a power or ability of performing an action. The term is much uſed by the ancient philoſophers, and ſtill retained in the ſchools for explaining the actions of natural bodies. Thus, to account for the act of digeſtion, they ſuppoſe a digeſtive faculty in the ſtomach: to account for motion, they imagine a motive faculty in the nerves, &c. which is only a ſubſtituting of one name of an unknown phenomenon for another. The faculties or powers of the ſoul are commonly reputed two, viz. the underſtanding and will. The faculties of the body are uſually diſtinguiſhed with regard to their ſeveral functions, into vegetative and animal. Under the vegetative faculty are comprehended the divers ſubaltern ones, whereby nutrition and generation are effected. Under the animal faculties are comprehended thoſe relating to ſenſe and motion. The vegetative faculty is ſubdivided into nutritive and generative, and the nutritive is again ſubdivided into natural and vital. To the firſt belong the functions of the lower belly, relating to the preparation of the food; to the latter, the actions of the heart and lungs, wherein life is chiefly concerned. Others ſubdivide the vegetative faculty into attractive, retentive, concoctive, and expulſive. The animal faculties being thoſe whereby an animal perceives and moves, become divided into ſenſitive and locomotive.

FACULTY is alſo applied in the ſchools, to the divers parts or members of an univerſity, divided according to the arts or ſciences taught or profeſſed there. There are four faculties in moſt univerſities; that of arts, which includes humanity and philoſophy, and is much the moſt ancient and extenſive: the ſecond is that of theology; the third, medicine; and the fourth, juriſprudence, civil or law. The degrees in the ſeveral faculties in the univerſities are thoſe of batchelor, maſter, and doctor.

FÆCES, or **FECES**, the dregs, ſediment, or impurities, remaining of a mixt body, after the purer, more volatile, and fluid, have been ſeparated from it by evaporation, diſſolution, decantation, derivation, or the like. Thus we ſay the fæces of wine, of oil, &c. Thoſe of wines are properly called lees; thoſe of oil, amurca; thoſe of malt-liquors, grounds.

FÆCES, in chymiſtry, denotes the lees, refuſe, dirt, mud, impurities, and heterogeneous matters, remaining in the alembic after the diſtillation of any body; what remains in the retort, inſtead of fæces, is properly denominated *caput mortuum, or terra damnata.*

FÆCES is particularly uſed in medicine, &c. for the groſs impure matters found at the bottom of the compoſitions and preparations of either pharmacy.

FÆCES is alſo uſed for the excrements of an animal voided by ſtool.

FAGUS, the **BEECH TREE**, a genus of the polyandria order, belonging to the monoecia claſs of plants. There are three ſpecies. 1. The ſylvaticus, or beech tree, riſes 60 or 70 feet high, and hath a proportionable thickneſs, branching upward into a fine regular head, garniſhed with oval ſerrated leaves, with flowers in globular catkins, ſucceeded by angular fruit called *maſt*. 2. The caſtanea, or cheſtnut tree, hath a large upright trunk growing 40 or 50 feet high, branching regularly round into a fine ſpreading head, garniſhed with large ſpear ſhaped acutely ſerrated leaves naked on the under ſide, having flowers in long amentums, ſucceeded by round prickly fruit, containing two or more nuts. 3. The pumila, dwarf cheſtnut tree, or chinkapin, riſes eight or ten feet high, with a branching ſhrubby ſtem, and oval, ſpear ſhaped, and acutely ſerrated leaves, hoary on the under ſide.

Culture. The firſt is very eaſily raiſed from the maſt or ſeed, which ripens in September, and may either be ſown then, or in a month or two after, or towards the ſpring. For this purpoſe, beds are to be prepared four feet wide. The earth is then to be raked evenly from the ſurface, about an inch deep; then ſow the maſt, and beat it gently down with the back of the ſpade, afterwards covering it up with earth to the above-mentioned depth. Many of the plants will come up in the ſpring, but others not till a year after; and when they are two years old, they muſt be planted out in nurſery rows two feet and a half aſunder, there to remain till they are four or five feet high, when they are to be tranſplanted to thoſe places where they are to continue. The ſecond and third ſorts are alſo propagated by ſeeds or nuts ſown in drills. The nuts ſometimes ripen perfectly in this country; but in default of this, there are vaſt quantities imported from Spain or Portugal. Theſe laſt are reckoned preferable even to the beſt ripened cheſtnuts of this country.

Properties. The firſt ſpecies ſpreads its branches very wide, and affords a grateful ſhade; but no verdure will thrive under it. The maſt, or ſeeds, yield a good oil for lamps; and are a very agreeable food to ſquirrels, mice, and ſwine. The fat of ſwine fed with them, however, is ſoft, and boils away unleſs hardened by ſome other food. The wood is brittle; very fiſſile; durable in water, but not in open air: it is the beſt of all woods for fuel, and is ſometimes uſed by the wheelwright and turner to make axes, ſpokes, bowls, &c. ſword ſcabbards are alſo made of it; and ſhoe makers laſts, and formerly book binders uſed it in making covers for books. The leaves gathered in autumn, before they are much injured by the froſts, make much better matraſſes than ſtraw or chaff; and laſt for ſeven or eight years. The nuts, when eaten by the human ſpecies, occaſion giddineſs and headach; when well dried and powdered, they make wholeſome bread. They are ſometime roaſted, and ſubſtituted for coffee. The poor people in Sileſia uſe the expreſſed oil inſtead of butter. The cheſtnut tree ſometimes grows to an immenſe ſize. The largeſt in the known world are thoſe which grow upon Mount Ætna in Sicily. At Tortworth in Gloceſterſhire, is a cheſtnut tree 52 feet round. It is proved to have ſtood there ever ſince the year 1150, and was then ſo remarkable that it was called the *great cheſtnut of Tortworth*. It fixes the boundary of the manor, and is probably near 1000 years old. The wood of the cheſtnut tree is applicable to the ſame purpoſes with the oak. If the bark is not taken off, it makes poles for eſpaliers, dead fences, and hop yards; and pipes to convey water under ground, which will laſt longer than elm or oak. Some of the oldeſt buildings in London are ſaid to be conſtructed with this wood. The nuts are uſed for whitening linen cloth, and for making ſtarch.

FAILURE, or **FAILING**, a bankruptcy, popularly called breaking or ſtopping payment.

FAINT, or **FAINT-ACTION**, in law, is as much as feigned action; that is, ſuch an action as, though the words of the writ be true, yet, for certain cauſes, the party has no title to recover thereby. By which it differs from falſe-action, which is that where the words of the writ are falſe. Sometimes the two are confounded.

FAINTS, in the diſtillery, the weak ſpirituous liquor that runs from the ſtill in rectifying the low wines after the proof-ſpirit is run off.

FAINTS is alſo the laſt runnings of all ſpirits diſtilled by the alembic. The clearing the worm of theſe is ſo eſſential a point in order to the obtaining a pure ſpirit by the ſucceeding diſtillation, that all others are fruitleſs without it.

FAINTING. Some people are apt to faint during the operation of bleeding. In all caſes, therefore, where plentiful bleeding is indicated, it is beſt to do it in bed, in order to prevent the patient's fainting. It is likewiſe obſerved, that a perſon will bear the loſs of a much greater quantity of blood if the ſtream is ſmall than by a large orifice, which ſome think neceſſary, for making a more ſpeedy revulſion. Pringle, Obſerv. on the Diſeaſes of the Army, p. 131.

FAIR, a public place, where merchants, traders, and other perſons, from divers parts, meet, on ſome fixed day in the year, to buy and ſell commodities, and to partake of the diverſions uſually accompanying ſuch aſſemblies: or it denotes the concourſe of people aſſembled on ſuch occaſions. The word *fair* is formed of the French *foire*, which ſignifies the ſame thing; and *foire* ſome derive from the Latin *forum, market*; others from the Latin *feriæ*, becauſe *fairs* anciently were always held in the places where the wakes, or feaſts, of the dedications of churches, called *feriæ*, were alſo held. The Romans called them *mundinæ*. Eric Puteanus has a pretty little treatiſe on the *fairs* of the Romans, De Nundinis Romanorum, which he calls *nova faſtorum facula*.

Fairs can only be eſtabliſhed by virtue of the king's grant, or by long and immemorial uſage and preſcription, which ſuppoſes ſuch a grant. The duration of fairs is determined by proclamation; and if a perſon ſhall ſell any goods after the time of the fair expires, he ſhall incur a forfeiture of double the value of the goods ſold, one fourth to the proſecutor, and the reſt to the king.

Fairs make a very conſiderable article in the commerce of Europe, eſpecially that of the Mediterranean or inland parts; as Germany, &c. where the continual paſſage and repaſſage of veſſels is impracticable.

The principal fairs in Great Britain are, Stourbridge fair, near Cambridge; the two fairs of Briſtol; that of Exeter, Weſt Cheſter, Edinburgh, Weyhill, and Burford, fairs for ſheep: Pancras fair, in Staffordſhire, for ſaddle horſes; Barnet fair, near London, for lean and Welſh black cattle; St. Faith's, in Norfolk, for Scots runts; Yarmouth fiſhing fair for herrings; Ipſwich butter fair; that of Woodborough Hill, near Blandford in Dorſetſhire, famous for weſt country manufactures, Devonſhire kerſeys, Wiltſhire druggets, &c. two cheeſe fairs at Atherſton and Chipping Norton; beſides many more fairs in different parts of the kingdom.

FAIR, in ſea language, is uſed for the diſpoſition of the wind, when it is favourable to a ſhip's courſe, in oppoſition to that which is contrary or foul. The term fair is more comprehenſive than large, and includes about ſixteen or eighteen points of the compaſs; whereas large is confined to the beam or quarter, that is, to a wind which croſſes the keel at right angles, or obliquely from the ſtern, but never to one right a-ſtern. Falconer's Marine Dict.

FAIRY, a term frequently occuring in ancient traditions and romances, denoting a kind of genii, or imaginary deities, converſant on earth, and diſtinguiſhed by abundance of fantaſtical actions and offices, either good or evil. The fairies, according to theſe traditions, are peculiar ſpecies of divinities, that have but little relation to any of thoſe of the ancient Greeks and Romans; unleſs, perhaps, to the larvæ; though others will not have them ranked among deities, but ſuppoſe them an intermediate kind of beings, neither gods, nor angels, nor men, nor devils.

They are of oriental extraction, and ſeem to have been invented by the Perſians and Arabs, whoſe hiſtory and religion abound with tales of fairies and dragons. The Perſians call them Peri, and the Arabs Ginn; having a peculiar country, which they ſuppoſe them to inhabit, called Ginniſtian; and, by us, Fairy land. Fairies have been likewiſe deſcribed as of either ſex, and generally as of minute ſtature, though capable of aſſuming various forms and dimenſions. The moſt charming repreſentation imaginable of theſe children of romantic fancy, is in the Midſummer-Night's Dream of Shakeſpear; in referring to which, we ſhall no doubt have been anticipated by the recollection of almoſt every reader. Spenſer's Fairy Queen is an epic poem, under the perſons and characters of fairies. This ſort of poetry raiſes a pleaſing kind of horror in the mind of the reader, and amuſes his imagination with the ſtrangeneſs and novelty of the perſons who are repreſented in it; but, as a vehicle of inſtruction, the judicious object to it, as not having probability enough to make any moral impreſſion.

The belief of fairies ſtill ſubſiſts in many parts of our own country. And in the Highlands of Scotland, new born children are watched till the chriſtening is over, leſt they ſhould be ſtolen or changed by ſome of theſe phantaſtical exiſtences.

FAITH, in philoſophy and theology, that aſſent which we give to a propoſition advanced by another, the truth of which we do not immediately perceive from our own reaſon or experience; or it is a judgment, or aſſent of the mind, the motive whereof is not any intrinſic evidence, but the authority, or teſtimony, of ſome other, who reveals or relates it. Hence, as there are two kinds of authorities and teſtimonies, the one of God, and the other of man, faith becomes diſtinguiſhed into divine and human.

Divine **FAITH**, is that founded on the authority of God; or it is that aſſent we give to what is revealed by God. The objects of this faith, therefore, are matters of revelation.

Human **FAITH**, is that whereby we believe what is told us by men. The object hereof is matter of human teſtimony and evidence.

FAITH, *Implicit* or *Blind*, is that whereby we give our aſſent to a propoſition advanced by another, of whoſe knowledge and veracity we have no certain and evident reaſon, or proof. This is only opinion, under another name.

All our preſent religious faith is really human, as depending on the ſecondary teſtimony of men; of whoſe veracity, however, we have the ſtrongeſt proofs. The prophets, or thoſe to whom God immediately revealed his will, believed him, becauſe they knew he could not deceive. We, at this day, believe them, or rather their writings, for other reaſons; viz. the ſame which oblige us to believe all well-atteſted hiſtories. See **EVIDENCE**. Beſides the two ſpecies of faith, human and divine, the Romaniſts make a third, or intermediate kind, called,

Eccleſiaſtical **FAITH**, which is the aſſent orthodox perſons give to certain events decided by the church, and enjoined to be believed by all. As, when the church declares, that ſuch a book contains heretical doctrine, &c. This term, eccleſiaſtical faith, was firſt introduced by Mr. Perefixe, to diſtinguiſh the faith whereby we believe matters of divine revelation, from that whereby we believe matters of eccleſiaſtical determination.

FAITH, in practical theology, makes the firſt of the theological virtues, or graces. Faith in God, in this ſenſe, denotes ſuch a conviction of his being, perfections, character, and government, as produces love, truſt, worſhip, obedience, and reſignation. Faith in Chriſt, as it has been defined by ſome, is a mere aſſent to the Goſpel as true; according to others, it ſignifies ſuch a perſuaſion that he is the Meſſiah, and ſuch a deſire and expectation of the bleſſings which he has promiſed in his Goſpel to his ſincere diſciples, as engage the mind to fix its dependence upon him, and ſubject itſelf to him in all the ways of holy obedience; and thus defined it is a very extenſive principle, and includes in its nature and inſeparable effects, the whole of moral virtue. In this ſenſe it has been ſaid, that under the Goſpel a man is juſtified by faith. Faith likewiſe, in reſpect to futurity, is a moral principle, implying ſuch a conviction of the reality and importance of a future ſtate, as is ſufficient to regulate the temper and conduct.

FAITHFUL, an appellation which the Mahometans aſſume to themſelves.

FAITHFULNESS, in ethics, is an agreement between a man's promiſes and his actions.

FAKIR, or **FAQUIR**, a kind of derviſe, or Mahometan religious, who travels the country, and lives on alms. See **DERVISE**.

FALCATED, one of the phaſes of the planets, popularly called horned. The aſtronomers ſay, the moon, or any planet, is falcated, when the enlightened part appears in form of a ſickle, or reaping-hook, by the Latins called falx.

FALCO, in ornithology, a genus belonging to the order of accipitres, the characters of which are theſe: the beak is crooked, and furniſhed with wax at the baſe; the head is thick ſet with feathers, and the tongue is cloven. The principal ſpecies are, eſpecially of man; and comprehends in the latter, all that part of the head which is not covered with the common long hair. The Latins call it *facies*, *vultus*, *os*, &c. The face, conſidered as the index of the paſſions, habits, &c. of the perſon, makes the ſubject of phyſiognomy. See PHYSIOGNOMY.

Anatomiſts uſually divide the face into two parts, the upper and lower: the upper is the front, or forehead; the lower includes the eyes, noſe, ears, mouth, and chin.

FACES *of Baſtion*, in fortification, are the two foremoſt ſides reaching from the flanks to the point of the baſtion where they meet. Theſe are commonly the firſt determinded, becauſe they reach fartheſt out, and are the leaſt flanked, and therefore weakeſt.

FACET, or FACETTE, a little face or ſide of a body, cut into a great number of angles. Multiplying glaſſes are cut in facets, or facet wiſe. Diamonds are alſo cut in facets or tables. In brilliants there are two ſorts, ſkew or ſkill facets, and ſtar facets. Skill facets are divided into upper and under. Upper ſkill facets are wrought on the lower part of the bezil, and terminate in the girdle. Under ſkill facets are wrought on the pavilions, and terminate in the girdle. Star facets are wrought on the upper part of the bezil, and terminate in the table. Jeffries on diamonds.

FACTION, a cabal or party formed in a ſtate to diſturb the public repoſe. The moſt celebrated factions are that of the Guelphs and Gibelins, who kept Italy in alarm for many ages; and with us that of the Whigs and Tories.

FACTOR, in commerce, an agent or perſon who acts and negociates for a merchant by commiſſion; called alſo commiſſioner, and on ſome occaſions broker, and throughout the Levant, coagis. Factors are either charged with the buying or the ſelling of goods, or with both. Thoſe of the firſt kind are uſually eſtabliſhed in places of conſiderable manufactories, or cities of great trade. Their office is to buy up commodities for merchants reſiding elſewhere; to ſee them packed, and ſend them to the perſons for whom they were bought. The duty of a factor is to procure the beſt intelligence of the ſtate of trade at his place of reſidence; of the courſe of exchange; of the quantity and quality of goods at market, their preſent price, and the probability that it may riſe or fall; to pay exact obedience to the orders of his employers; to conſult their advantage in matters referred to his direction; to execute their buſineſs with all the diſpatch that circumſtances admit; to be early in his intelligence, diſtinct in his accounts, and punctual in his correſpondence.

FACTORS *of Sale* are uſually fixed in places where there is a great trade. To theſe, merchants and manufacturers ſend their goods to be ſold for them according to the price and other conditions expreſſed in the orders delivered them. The wages or allowances for ſelling are uſually clear of all expences of carriage, exchange, remittances, &c. excepting poſtage of letters, which are never put to account. Factors ſhould ſtrictly obſerve the orders of their principals, or elſe they are liable to the damage accruing from the neglect of them. When factors have unlimited commiſſion to do for their conſtituents the beſt they can, they are excuſable, though their tranſactions are attended with loſs to their principals; but no factor, who has merely a commiſſion to ſell, &c. for another, is excuſable for entruſting another perſon beyond the uſual time allowed in the ſale of the commodities which he diſpoſes of: in ſuch a caſe he is anſwerable to the principal out of his own eſtate.

A factor that ſells a commodity under the price ordered by his principal ſhall be obliged to make good the difference; and if he purchaſes goods for another at a limited price, and they riſe in value, and he ſecures to himſelf the advantage, he is obliged to ſatisfy his principal for damages; or if he makes any advantage of the ſale of goods which his principal directed him to purchaſe, the principals ſhall recover it from him, and he is liable to be amerced for the fraud.

A factor who has money in hand belonging to his principals, and who neglects to inſure a ſhip and goods according to order, ſhall make good the damage if the ſhip miſcarry; and if he makes any compoſition with the inſurers after inſurance without orders, he is anſwerable for the whole inſurance. As fidelity and diligence are required from the factors, ſo the law requires the like from the principal: if, therefore, a perſon remits counterfeit jewels to his factor, who ſells them as true ones, and ſuſtains loſs or damage by impriſonment or other puniſhment, the principal ſhall not make ſatisfaction to the factor but to the party who purchaſed them. Buſineſs of this kind is called commiſſion-buſineſs; and traders in this way have current as well as commiſſion accounts conſtantly between them, and draw on, remit to, and ſend commiſſions to each other only by the intercourſe of letters, which among men of honour, are as obligatory and authoritative as all the bonds and ties of law.

FACTORAGE. The factorage or wages, called alſo commiſſion, is different at different places, and for different voyages; at a medium it may be fixed at about three per cent. of the value of the goods bought, beſide the charge of package, which is paid over and above. At Virginia, Barbadoes, and Jamaica, the factorage is about eight per cent. and the like throughout the greateſt part of the Weſt Indies. In Italy it is two and a half; in Holland one and a half; in Spain, Portugal, France, &c. it is two per cent.

FACTORY, a place where a conſiderable number of factors reſide to negociate and officiate for their maſters or principals. The term is chiefly uſed in ſpeaking of the Eaſt Indies, and other parts of Aſia, Turky, Italy, Portugal, &c. whither the European nations ſend their ſhips every year, and where they keep factors to buy the commodities of the country, and ſell thoſe brought from Europe. The moſt conſiderable factories belonging to the Britiſh are thoſe eſtabliſhed in the Eaſt-Indies, Portugal, Turky, &c.

FACULTY, a power or ability of performing an action. The term is much uſed by the ancient philoſophers, and ſtill retained in the ſchools for explaining the actions of natural bodies. Thus, to account for the act of digeſtion, they ſuppoſe a digeſtive faculty in the ſtomach: to account for motion, they imagine a motive faculty in the nerves, &c. which is only a ſubſtituting of one name of an unknown phenomenon for another. The faculties or powers of the ſoul are commonly reputed two, viz. the underſtanding and will. The faculties of the body are uſually diſtinguiſhed with regard to their ſeveral functions, into vegetative and animal. Under the vegetative faculty are comprehended the divers ſubaltern ones, whereby nutrition and generation are effected Under the animal faculties are comprehended thoſe relating to ſenſe and motion. The vegetative faculty is ſubdivided into nutritive and generative, and the nutritive is again ſubdivided into natural and vital. To the firſt belong the functions of the lower belly, relating to the preparation of the food; to the latter, the actions of the heart and lungs, wherein life is chiefly concerned. Others ſubdivide the vegetative faculty into attractive, retentive, concoctive, and expulſive. The animal faculties being thoſe whereby an animal perceives and moves, become divided into ſenſitive and locomotive.

FACULTY is alſo applied in the ſchools, to the divers parts or members of an univerſity, divided according to the arts or ſciences taught or profeſſed there. There are four faculties in moſt univerſities; that of arts, which includes humanity and philoſophy, and is much the moſt ancient and extenſive: the ſecond is that of theology; the third, medicine; and the fourth, juriſprudence, civil or law. The degrees in the ſeveral faculties in the univerſities are thoſe of batchelor, maſter, and doctor.

FÆCES, or FECES, the dregs, ſediment, or impurities, remaining of a mixt body, after the purer, more volatile, and fluid, have been ſeparated from it by evaporation, diſſolution, decantation, derivation, or the like. Thus we ſay the fæces of wine, of oil, &c. Thoſe of wines are properly called lees; thoſe of oil, amurca; thoſe of malt-liquors, grounds.

FÆCES, in chymiſtry, denotes the lees, refuſe, dirt, mud, impurities, and heterogeneous matters, remaining in the alembic after the diſtillation of any body; what remains in the retort, inſtead of fæces, is properly denominated *caput mortuum, or terra damnata.*

FÆCES is particularly uſed in medicine, &c. for the groſs impure matters found at the bottom of the compoſitions and preparations of either pharmacy.

FÆCES is alſo uſed for the excrements of an animal voided by ſtool.

FAGUS, the BEECH TREE, a genus of the polyandria order, belonging to the monœcia claſs of plants. There are three ſpecies. 1. The ſylvaticus, or beech tree, riſes 60 or 70 feet high, and hath a proportionable thickneſs, branching upward into a fine regular head, garniſhed with oval ſerrated leaves, with flowers in globular catkins, ſucceeded by angular fruit called *maſt*. 2. The caſtanea, or cheſtnut tree, hath a large upright trunk growing 40 or 50 feet high, branching regularly round into a fine ſpreading head, garniſhed with large ſpear ſhaped acutely ſerrated leaves naked on the under ſide, having flowers in long amentums, ſucceeded by round prickly fruit, containing two or more nuts. 3. The pumila, dwarf cheſtnut tree, or chinkapin, riſes eight or ten feet high, with a branching ſhrubby ſtem, and oval, ſpear ſhaped, and acutely ſerrated leaves, hoary on the under ſide.

Culture. The firſt is very eaſily raiſed from the maſt or ſeed, which ripens in September, and may either be ſown then, or in a month or two after, or towards the ſpring. For this purpoſe, beds are to be prepared four feet wide. The earth is then to be raked evenly from the ſurface, about an inch deep; then ſow the maſt, and beat it gently down with the back of the ſpade, afterwards covering it up with earth to the above-mentioned depth. Many of the plants will come up in the ſpring, but others not till a year after; and when they are two years old, they muſt be planted out in nurſery rows two feet and a half aſunder, there to remain till they are four or five feet high, when they are to be tranſplanted to thoſe places where they are to continue. The ſecond and third ſorts are alſo propagated by ſeeds or nuts ſown in drills. The nuts ſometimes ripen perfectly in this country; but in default of this, there are vaſt quantities imported from Spain or Portugal. Theſe laſt are reckoned preferable even to the beſt ripened cheſtnuts of this country.

Properties. The firſt ſpecies ſpreads its branches very wide, and affords a grateful ſhade; but no verdure will thrive under it. The maſt, or ſeeds, yield a good oil for lamps; and are a very agreeable food to ſquirrels, mice, and ſwine. The fat of ſwine fed with them, however, is ſoft, and boils away unleſs hardened by ſome other food. The wood is brittle; very fiſſile; durable in water, but not in open air: it is the beſt of all woods for fuel, and is ſometimes uſed by the wheelwright and turner to make axes, ſpokes, bowls, &c. ſword ſcabbards are alſo made of it; and ſhoe makers laſts, and formerly book binders uſed it in making covers for books. The leaves gathered in autumn, before they are much injured by the froſts, make much better matraſſes than ſtraw or chaff; and laſt for ſeven or eight years. The nuts, when eaten by the human ſpecies, occaſion giddineſs and headach; when well dried and powdered, they make wholeſome bread. They are ſometime roaſted, and ſubſtituted for coffee. The poor people in Sileſia uſe the expreſſed oil inſtead of butter. The cheſtnut tree ſometimes grows to an immenſe ſize. The largeſt in the known world are thoſe which grow upon Mount Ætna in Sicily. At Tortworth in Glouceſterſhire, is a cheſtnut tree 52 feet round. It is proved to have ſtood there ever ſince the year 1150, and was then ſo remarkable that it was called the *great cheſtnut of Tortworth*. It fixes the boundary of the manor, and is probably near 1000 years old. The wood of the cheſtnut tree is applicable to the ſame purpoſes with the oak. If the bark is not taken off, it makes poles for eſpaliers, dead fences, and hop yards; and pipes to convey water under ground, which will laſt longer than elm or oak. Some of the oldeſt buildings in London are ſaid to be conſtructed with this wood. The nuts are uſed for whitening linen cloth, and for making ſtarch.

FAILURE, or **Failing**, a bankruptcy, popularly called breaking or ſtopping payment.

FAINT, or **Faint-Action**, in law, is as much as feigned action; that is, ſuch an action as, though the words of the writ be true, yet, for certain cauſes, the party has no title to recover thereby. By which it differs from falſe-action, which is that where the words of the writ are falſe. Sometimes the two are confounded.

FAINTS, in the diſtillery, the weak ſpirituous liquor that runs from the ſtill in rectifying the low wines after the proof-ſpirit is run off.

Faints is alſo the laſt runnings of all ſpirits diſtilled by the alembic. The clearing the worm of theſe is ſo eſſential a point in order to the obtaining a pure ſpirit by the ſucceeding diſtillation, that all others are fruitleſs without it.

FAINTING. Some people are apt to faint during the operation of bleeding. In all caſes, therefore, where plentiful bleeding is indicated, it is beſt to do it in bed, in order to prevent the patient's fainting. It is likewiſe obſerved, that a perſon will bear the loſs of a much greater quantity of blood if the ſtream is ſmall than by a large orifice, which ſome think neceſſary, for making a more ſpeedy revulſion. Pringle, Obſerv. on the Diſeaſes of the Army, p. 131.

FAIR, a public place, where merchants, traders, and other perſons, from divers parts, meet, on ſome fixed day in the year, to buy and ſell commodities, and to partake of the diverſions uſually accompanying ſuch aſſemblies: or it denotes the concourſe of people aſſembled on ſuch occaſions. The word *fair* is formed of the French *foire*, which ſignifies the ſame thing; and *foire* ſome derive from the Latin *forum, market*; others from the Latin *feriæ*, becauſe *fairs* anciently were always held in the places where the wakes, or feaſts, of the dedications of churches, called *feriæ*, were alſo held. The Romans called them *mundinæ*. Eric Puteanus has a pretty little treatiſe on the *fairs* of the Romans, De Nundinis Romanorum, which he calls *nova faſtorum facula*.

Fairs can only be eſtabliſhed by virtue of the king's grant, or by long and immemorial uſage and preſcription, which ſuppoſes ſuch a grant. The duration of fairs is determined by proclamation; and if a perſon ſhall ſell any goods after the time of the fair expires, he ſhall incur a forfeiture of double the value of the goods ſold, one fourth to the proſecutor, and the reſt to the king.

Fairs make a very conſiderable article in the commerce of Europe, eſpecially that of the Mediterranean or inland parts; as Germany, &c. where the continual paſſage and repaſſage of veſſels is impracticable.

The principal fairs in Great Britain are, Stourbridge fair, near Cambridge; the two fairs of Briſtol; that of Exeter, Weſt Cheſter, Edinburgh, Weyhill, and Burford, fairs for ſheep: Pancras fair, in Staffordſhire, for ſaddle horſes; Barnet fair, near London, for lean and Welſh black cattle; St. Faith's, in Norfolk, for Scots runts; Yarmouth fiſhing fair for herrings; Ipſwich butter fair; that of Woodborough Hill, near Blandford in Dorſetſhire, famous for weſt country manufactures, Devonſhire kerſeys, Wiltſhire druggets, &c. two cheeſe fairs at Atherſton and Chipping Norton; beſides many more fairs in different parts of the kingdom.

Fair, in ſea language, is uſed for the diſpoſition of the wind, when it is favourable to a ſhip's courſe, in oppoſition to that which is contrary or foul. The term fair is more comprehenſive than large, and includes about ſixteen or eighteen points of the compaſs; whereas large is confined to the beam or quarter, that is, to a wind which croſſes the keel at right angles, or obliquely from the ſtern, but never to one right a-ſtern. Falconer's Marine Dict.

FAIRY, a term frequently occuring in ancient traditions and romances, denoting a kind of genii, or imaginary deities, converſant on earth, and diſtinguiſhed by abundance of fantaſtical actions and offices, either good or evil. The fairies, according to theſe traditions, are peculiar ſpecies of divinities, that have but little relation to any of thoſe of the ancient Greeks and Romans; unleſs, perhaps, to the larvæ; though others will not have them ranked among deities, but ſuppoſe them an intermediate kind of beings, neither gods, nor angels, nor men, nor devils.

They are of oriental extraction, and ſeem to have been invented by the Perſians and Arabs, whoſe hiſtory and religion abound with tales of fairies and dragons. The Perſians call them Peri, and the Arabs Ginn; having a peculiar country, which they ſuppoſe them to inhabit, called Ginniſtian; and, by us, Fairy land. Fairies have been likewiſe deſcribed as of either ſex, and generally as of minute ſtature, though capable of aſſuming various forms and dimenſions. The moſt charming repreſentation imaginable of theſe children of romantic fancy, is in the Midſummer-Night's Dream of Shakeſpear; in referring to which, we ſhall no doubt have been anticipated by the recollection of almoſt every reader. Spenſer's Fairy Queen is an epic poem, under the perſons and characters of fairies. This ſort of poetry raiſes a pleaſing kind of horror in the mind of the reader, and amuſes his imagination with the ſtrangeneſs and novelty of the perſons who are repreſented in it; but, as a vehicle of inſtruction, the judicious object to it, as not having probability enough to make any moral impreſſion.

The belief of fairies ſtill ſubſiſts in many parts of our own country. And in the Highlands of Scotland, new born children are watched till the chriſtening is over, leſt they ſhould be ſtolen or changed by ſome of theſe phantaſtical exiſtences.

FAITH, in philoſophy and theology, that aſſent which we give to a propoſition advanced by another, the truth of which we do not immediately perceive from our own reaſon or experience; or it is a judgment, or aſſent of the mind, the motive whereof is not any intrinſic evidence, but the authority, or teſtimony, of ſome other, who reveals or relates it. Hence, as there are two kinds of authorities and teſtimonies, the one of God, and the other of man, faith becomes diſtinguiſhed into divine and human.

Divine **Faith**, is that founded on the authority of God; or it is that aſſent we give to what is revealed by God. The objects of this faith, therefore, are matters of revelation.

Human **Faith**, is that whereby we believe what is told us by men. The object hereof is matter of human teſtimony and evidence.

Faith, *Implicit* or *Blind*, is that whereby we give our aſſent to a propoſition advanced by another, of whoſe knowledge and veracity we have no certain and evident reaſon, or proof. This is only opinion, under another name.

All our preſent religious faith is really human, as depending on the ſecondary teſtimony of men; of whoſe veracity, however, we have the ſtrongeſt proofs. The prophets, or thoſe to whom God immediately revealed his will, believed him, becauſe they knew he could not deceive. We, at this day, believe them, or rather their writings, for other reaſons; viz. the ſame which oblige us to believe all well-atteſted hiſtories. See Evidence. Beſides the two ſpecies of faith, human and divine, the Romaniſts make a third, or intermediate kind, called,

Eccleſiaſtical **Faith**, which is the aſſent orthodox perſons give to certain events decided by the church, and enjoined to be believed by all. As, when the church declares, that ſuch a book contains heretical doctrine, &c. This term, eccleſiaſtical faith, was firſt introduced by Mr. Perefixe, to diſtinguiſh the faith whereby we believe matters of divine revelation, from that whereby we believe matters of eccleſiaſtical determination.

Faith, in practical theology, makes the firſt of the theological virtues, or graces. Faith in God, in this ſenſe, denotes ſuch a conviction of his being, perfections, character, and government, as produces love, truſt, worſhip, obedience, and reſignation. Faith in Chriſt, as it has been defined by ſome, is a mere aſſent to the Goſpel as true; according to others, it ſignifies ſuch a perſuaſion that he is the Meſſiah, and ſuch a deſire and expectation of the bleſſings which he has promiſed in his Goſpel to his ſincere diſciples, as engage the mind to fix its dependence upon him, and ſubject itſelf to him in all the ways of holy obedience; and thus defined it is a very extenſive principle, and includes in its nature and inſeparable effects, the whole of moral virtue. In this ſenſe it has been ſaid, that under the Goſpel a man is juſtified by faith. Faith likewiſe, in reſpect to futurity, is a moral principle, implying ſuch a conviction of the reality and importance of a future ſtate, as is ſufficient to regulate the temper and conduct.

FAITHFUL, an appellation which the Mahometans aſſume to themſelves.

FAITHFULNESS, in ethics, is an agreement between a man's promiſes and his actions.

FAKIR, or **Faquir**, a kind of derviſe, or Mahometan religious, who travels the country, and lives on alms. See Derviſe.

FALCATED, one of the phaſes of the planets, popularly called horned. The aſtronomers ſay, the moon, or any planet, is falcated, when the enlightened part appears in form of a ſickle, or reaping-hook, by the Latins called falx.

FALCO, in ornithology, a genus belonging to the order of accipitres, the characters of which are theſe: the beak is crooked, and furniſhed with wax at the baſe; the head is thick ſet with feathers, and the tongue is cloven. The principal ſpecies are, The coronatus, or crowned eagle of Edwards, with aſh coloured wax; the legs are covered with white downy feathers, interſperſed with black ſpots; the breaſt is reddiſh; and there are black belts on the ſides. It is a native of Guinea. The oſſifragus, or ſea eagle, with yellow wax, and half feathered legs; is about the ſize of a peacock; the feathers are white at the baſe, iron coloured in the middle, and black at the points; and the legs are yellow. It is found in ſeveral parts of Great Britain and Ireland. Mr. Willoughby tells us, that there was an aery of them in Whinfield Park, Weſtmoreland; and the bird ſoaring in the air with a cat in its talons, which Barlow drew from the very fact which he ſaw in Scotland, is of this kind. The cat's reſiſtance brought both animals to the ground, when Barlow took them up; and afterwards cauſed the event to be engraved in the 36th plate of his Collection of Prints. Turner ſays, that in his days this bird was too well known in England; for it made horrible deſtruction among the fiſh. All authors indeed agree, that it feeds principally on fiſh; which it takes, as they are ſwimming, near the ſurface, by darting itſelf down upon them.

The chryſaëtos, or golden eagle, weighs about 12 pounds and is in length about three feet, the wings, when extended, meaſuring about ſeven feet four inches. The ſight and ſenſe of ſmelling are very acute: the head and neck are cloathed with narrow, ſharp pointed feathers, of a deep brown colour bordered with tawney; the hind part of the head in particular is of a bright ruſt colour. Theſe birds are very deſtructive to fawns, lambs, kids, and all kinds of game; particularly in the breeding ſeaſon, when they bring a vaſt quantity of prey to their young. Smith, in his hiſtory of Kerry, relates, that a poor man in that country got a comfortable ſubſiſtence for his family, during a ſummer of famine, out of an eagle's neſt, by robbing the eaglets of the food the old ones brought; whoſe attendance he protracted beyond the natural time, by clipping the wings and retarding the flight of the former. It is very unſafe to leave infants in places where eagles frequent; there being inſtances in Scotland of two being carried off by them; but, fortunately, the theft was diſcovered in time, and the children were reſtored unhurt out of the eagles neſts. Yet quick as her ſight may be, her ſenſe of hearing ſeems ſtill more exquiſite. If hooded crows or ravens happen to be nearer the carrion, and reſort to it firſt, and give a ſingle croak, the eagle is certain of inſtantly repairing to the ſpot.

The fulvus, is common to the northern parts of Europe and America; that figured by Mr. Edwards differing from our ſpecies only in having ſome white ſpots on the breaſt. It is frequent in Scotland; where it is called the black eagle, from the dark colour of its plumage. It is very deſtructive to deer, which it will ſeize between the horns; and, by inceſſantly beating it about the eyes with its wings, ſoon makes a prey of the harraſſed animal. The eagles in the iſle of Rum have nearly extirpated the ſtags that uſed to abound there. This ſpecies generally builds in clefts of rocks near the deer foreſts; and makes great havock not only among them, but alſo among the white hares and ptarmigans. It is of equal ſize with the preceding, and is eaſily diſtinguiſhed from all the other ſpecies by a band of white on the upper part of the tail; the end only being of a deep brown. The legs are feathered to the feet, the toes yellow, the claws black.

The cæruleſcens, with yellow wax, a yellow ring round the eyes, and the feet yellow underneath; the back is of a blackiſh blue colour; and the temples are ſurrounded with a white line. This is the ſmalleſt bird of the genus, and is a native of Aſia.

The milvus, or kite, is a native of Europe, Aſia, and Africa. Bellonius relates, that, about the end of April, incredible numbers of them are ſeen flying over the Black Sea into Aſia. Its motion in the air diſtinguiſhes it from all other birds, being ſo ſmooth and even that it is ſcarce perceptible. Sometimes it will remain quite motionleſs for a conſiderable ſpace: at others, glide through the ſky, without the leaſt apparent action of its wings; from thence deriving the old name of *glead* or *glede*, from the Saxon *glida*. The tail of this bird, as being forked, is ſufficient to diſtinguiſh it from moſt other birds of prey. The kites vary in their colours. Mr. Pennant mentions a beautiful variety ſhot in Lincolnſhire, that was entirely of a tawny colour. Some have ſuppoſed them to be birds of paſſage, but in Britain they certainly continue the whole year.

The gentilis, or gentil falcon, inhabits the north of Scotland, and was in high eſteem as a bold and ſpirited bird in the days of falconry. It makes its neſt in rocks: it is larger than the goſhawk.

The buteo, or buzzard, is the moſt common of the hawk kind in England. It breeds in large woods; and uſually builds on an old crow's neſt, which it enlarges, and lines with wool and other ſoft materials. It lays two or three eggs, which are ſometimes perfectly white, ſometimes ſpotted with yellow. The cock buzzard will hatch and bring up the young if the hen is killed. The young keep company with the old ones for ſome little time after they quit the neſt; which is not uſual with other birds of prey, who always drive away their brood as ſoon as they can fly. It feeds on birds, rabbits, moles, and mice; it will alſo eat frogs, earthworms, and inſects. This bird is ſubject to ſome variety in its colours.

Haliætus, the fiſhing-hawk of Cateſby, or the oſpray, weighs three pounds and a quarter; it meaſures, from one end of the wing to the other, five feet and a half. The feathers of the thighs are ſhort, and adhere cloſe to them, contrary to others of the hawk kind, which nature ſeems to have deſigned for the more eaſily penetrating the water. Their manner of fiſhing is, after hovering a while over the water, to precipitate into it with prodigious ſwiftneſs; where they remain for ſome minutes, and ſeldom riſe without a fiſh. The white-headed eagle, who is generally on the watch, no ſooner ſpies him with his fiſh, than he flies furiouſly upon him: the hawk immediately mounts, and ſcreams out; but the eagle always ſoars above him, and compels him to let the fiſh fall: the eagle inſtantly darts down upon the fiſh, and ſeldom fails to catch it before it reaches the water. It is remarkable, that, whenever the hawk catches a fiſh he calls out, as if it were to give warning to his enemy the eagle, who always obeys the call, if within hearing. The lower parts of the rivers and creeks near the ſea in America, abound with theſe eagles and hawks, where ſuch diverting conteſts are often ſeen.

The gyrfalco, or gyrſalcon, with blue wax on the beak, yellow legs, a brown body marked with aſh-coloured ſtreaks underneath, and the ſides of the tail white. It is the gyrfalco of all the ornithologiſts except Linnæus, whoſe bird is unknown to the reſt. It is a native of Europe; and feeds upon cranes, pigeons, &c.

The niſus, or ſparrow-hawk, with green wax, yellow legs, a white belly undulated with grey, and the tail marked with blackiſh belts. This is the moſt pernicious hawk we have; and makes great havock among pigeons as well as partridges. It builds in hollow trees, in old neſts of crows, large ruins, and high rocks: it lays four white eggs, encircled near the blunter end with red ſpecks.

FALCON, or **Faucon**, a bird of prey of the hawk kind, ſuperior to all others for courage, docility, gentleneſs, and nobleneſs of nature. Several authors take the name falcon to have been occaſioned by its crooked talons or pounces, which reſemble a falx or ſickle. Giraldus derives it *a falcando*, becauſe it flies in a curve. See Plate I. ORNITHOLOGY.

The falcon, or falcon gentle, is both for the fiſt and for the lure. In the choice, take one that has wide noſtrils, high and large eye-lids, a large black eye; a round head, ſomewhat full on the top; barb feathers on the clap of the beaks, which ſhould be ſhort, thick, and of an azure colour; the breaſt large, round, and fleſhy; and the thighs, legs, and feet, large and ſtrong; with the ſear of the foot ſoft and bluiſh: the pounces ſhould be black, with wings long and croſſing the train, which ſhould be ſhort and very pliable.

The name falcon is reſtrained to the female: for the male is much ſmaller, weaker, and leſs courageous, than the female; and therefore is denominated taſſel, or tircelet. The falcon is excellent at the river, brook, and even field; and flies chiefly at the larger game, as wild-gooſe, kite, crow, heron, crane, pye, ſhoveler, &c. For further particulars, ſee FALCONRY, HAWK, and HAWKING.

FALCONER, a perſon who brings up, tames, and makes, that is, tutors and manages birds of prey; as falcons, hawks, &c.

The grand ſeignior uſually keeps 1000 falconers in his ſervice. The French king has a grand falconer, which is an office diſmembered from that of great hunt, *grand venur*. Hiſtorians take notice of this poſt as early as the year 1250.

FALCONRY, or **Fauconry**, the art of taming, managing, and tutoring, birds of prey, particularly falcons and hawks; and employing them with advantage in the purſuit of game; called alſo hawking. See HAWKING.

FALL, *deſcent*, in phyſics, the tendency of any heavy body towards the centre of the earth. Galileo firſt diſcovered the ratio of the acceleration of falling bodies; viz. that dividing the whole time of falling into equal parts, the body will fall thrice as far in the ſecond moment, as in the firſt; five times as far in the third; ſeven times in the fourth, &c. and ſo on in the order of the uneven numbers. See ACCELERATION.

Fall is alſo uſed in a moral ſenſe: as, the fall of Adam; the fall of the Roman empire, &c.

Fall, among ſeamen, denotes that part of the rope of a tackle which is haled upon. They ſay alſo that a ſhip hath falls when ſhe is not fluſh, but hath riſings of ſome parts of her decks more than others. Alſo a ſhip is ſaid to fall off, when being under ſail ſhe keeps not ſo near the wind as ſhe ſhould do.

FALLACY, a deception, fraud, or falſe appearance. The Epicureans deny that there is any ſuch thing as a fallacy of the ſenſes: for, according to them, all our ſenſations and perceptions, both of ſenſe and phantaſy, are true; whence they make ſenſe the primary criterion of truth.

The Carteſians, on the other hand, maintain, that we ſhould ſuſpect as falſe, or at moſt as dubious, every thing that preſents itſelf to us by means only of the external ſenſes, becauſe they frequently deceive us. They add, that our ſenſes, as being fallacious, were never given us by nature for the diſcovery of truth, or the contemplation of the principles of things; but only for pointing out to us what things are convenient or hurtful to our bodies.

The peripatetics keep a middle courſe. They ſay, that if a ſenſible object be taken in its common or general view, the ſenſe cannot be deceived; but that if the object be taken under its ſpecific view, the ſenſe may be miſtaken, from the want of the diſpoſitions neceſſary to a juſt ſenſation, as a diſorder in the organ, or any thing uncommon in the medium: thus, in ſome diſorders of the eye, all objects appear yellow; a ſtick in water appears broken or crooked, &c.

Fallacy, in logic, or ſyllogyſtic fallacy, is a captious argument, called alſo a ſophiſm. Fallacies either ariſe from words, or things: the foundation of an illuſion and fallacy in words, is ambiguity.

FALLING *Sickneſs*. See **Epilepsy**.

FALLOPIAN *Tubes*, in anatomy, two ducts ariſing from the womb, one on each ſide of the fundus, and thence extended to the ovaries; having a conſiderable ſhare in conception. See Syſtem of **Anatomy** for deſcription Part V. Sect. XII. For repreſentation, ſee Plate X, *fig*. 1, Letters DD.

FALLOW *Field*, or *Fallow Ground*, is land laid up, or that has lain untilled for a conſiderable time. See Syſtem of **Agriculture**, cloſe of Sect. XXIX.

FALSE, in general, ſomething contrary to truth, or not what it ought to be; thus we ſay a falſe action, falſe weights, falſe claim, &c.

False *Action*, if brought againſt one whereby he is caſt into into priſon, and dies pending the ſuit, the law gives no remedy in this caſe, becauſe the truth or falſehood of the matter cannot appear before it is tried: and if the plaintiff is barred, or non-ſuited at common law, regularly all the puniſhment is amercement.

False *Impriſonment*, is a treſpaſs committed againſt a perſon, by arreſting and impriſoning him without juſt cauſe, contrary to law; or where a man is unlawfully detained without legal proceſs: and it is alſo uſed for a writ which is brought for this treſpaſs. If a perſon be any way unlawfully detained, it is falſe impriſonment; and conſiderable damages are recoverable in thoſe actions.

False *Oath*. See **Perjury**.

FALSHOOD, **Falsity**, in philoſophy, an act of the underſtanding, repreſenting a thing otherwiſe than it is, as to its accidents; or falſe judgment of any thing.

FALX, in anatomy, a part of the dura mater, deſcending between the two hemiſpheres of the brain, and ſeparating the forepart from the hinder. It is called falx, i. e. ſickle, becauſe of its curvature, occaſioned by the convexity of the brain. It divides the brain as low as the corpus calloſum. See Syſtem of **Anatomy**, Part VI. Sect. I.

FAME, a heathen goddeſs, celebrated chiefly by the poets. She is feigned to have been the laſt of the race of Titans produced by the earth, to have her palace in the air, and to have a vaſt number of eyes, ears, and tongues. She is mentioned by Heſiod, and particularly deſcribed by Ovid and Virgil.

Fames *Canina*, by the Greeks called *cynodes orexis*, q. d. *dog appetite*, is ſuch an inſatiable hunger as is not to be ſatisfied with eating, but continues even when the ſtomach is full.

FAMILY, denotes the perſons that live together in one houſe, under the direction of one head or chief manager. It alſo ſignifies the kindred or lineage of a perſon.

Family, in natural hiſtory, a ſubordinate diſtinction. It has been too common with compilers of dictionaries to confound the words, claſs, order, genus, and family. The latter evidently denotes this diſtinction. For inſtance the genus ſimia or monkey is diſtributed into three families. 1. Simiæ apes, ſuch as want tails; 2. Cercopithici, monkies, ſuch as have tails; 3. Papiones, baboons, thoſe with ſhort tails, to diſtinguiſh them from the common monkeys, which have very long ones. So that family points out diſtinction of ſpecies, or one of the ſame genus.

FAN, a machine uſed to raiſe wind, and cool the air by agitating it. The cuſtom which now prevails of wearing fans was borrowed from the eaſt, where they are almoſt indiſpenſibly neceſſary for keeping off the ſun and the flies.

FANATICS, wild, enthuſiaſtic, viſionary perſons, who pretend to revelation and inſpiration. The ancients called thoſe *fanatici* who paſſed their time in temples *(fana)*, and being often ſeized, with a kind of enthuſiaſm, as if inſpired by the divinity, ſhewed wild and antic geſtures. Prudentius repreſents them as cutting and ſlaſhing their arms with knives. Shaking the head was alſo common among the fanatici; for Lampridius informs us, that the emperor Heliogabulus was arrived to that pitch of madneſs, as to ſhake his head with the gaſhed fanatics. Hence the word was applied among us to the Anabaptiſts, Quakers, &c. at their firſt riſe, and is now an epithet given to the modern prophets, muggletonians, &c.

FANCY, or imagination. See **Imagination**.

FANUM, among the Romans, a temple or place conſecrated to ſome deity. The deified men and women among the heathens had likewiſe their fana; even the great philoſopher Cicero erected one to his daughter Tullia.

FARCE, was originally a droll, petty ſhew, or entertainment, exhibited by charletans, and their buffoons, in the open ſtreet, to gather the crowd together. The word is French, and ſignifies literally, "force-meat or ſtuffing." It was applied on this occaſion, no doubt, on account of the variety of jeſts, gibes, tricks, &c. wherewith the entertainment was interlarded. Some authors derive farce from the Latin *facetia*; others from the Celtic *farce*, mockery; others from the Latin *faccire*, to ſtuff. At preſent it is removed from the ſtreet to the theatre; and inſtead of being performed by merry-andrews to amuſe the rabble, is acted by comedians, and become the entertainment of a polite audience. Poets have reformed the wildneſs of the primitive farces, and brought them to the taſte and manner of comedy. The difference between the two on our ſtage is, that comedy keeps to nature and probability, and therefore is confined to certain laws preſcribed by ancient critics; whereas farce diſallows of all laws, or rather ſets them aſide on occaſion. Its end is purely to make merry; and it ſticks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is uſually low, the perſons of inferior rank, the fable or action trivial or ridiculous, and nature and truth every where heightened and exaggerated to afford the more palpable ridicule.

FARCIN, or **Farcy**, a diſeaſe in horſes, &c. ſomewhat of the nature of a ſcabies or mange. See Syſtem of **Farriery**.

FARE, a voyage or paſſage, or the money paid for paſſing by water, &c. For the fares of hackney coachmen, watermen, &c. ſee *Hackney* **Coaches**, and **Watermen**.

FARINA, the flour or powder of ſome ſort of grain or pulſe, ground or ſifted from the bran. The word is formed of *far*, *corn-wheat*; and *far*, according to Guichard, comes from the Hebrew גר, *bar*, ſignifying the ſame thing.

FARM, **Farin**, or **Firm**, *(Firma)*, in law, ſignifies a little country meſſuage, or diſtrict; containing houſe and land, with other conveniences; hired, or taken by leaſe, either in writing, or parole, under a certain yearly rent. See **Lease**.

This in divers parts is differently termed: in the north, it is a *tack*; in Lancaſhire a *fermeholt*; in Eſſex, a *wike*, &c.

Culture of a **Farm**. See **Agriculture**.

Farm, as connected with gardening, and ſuſceptible of embelliſhment. See **Gardening**:

In ſpeculation, it might have been expected that the firſt eſſay of improvement ſhould have been on a farm, to make it both advantageous and delightful; but the fact was otherwiſe: a ſmall plot was appropriated to pleaſure; the reſt was reſerved for profit only. And this may, perhaps, have been a principal cauſe of the vicious taſte which long prevailed in gardens. It was imagined that a ſpot ſet apart from the reſt ſhould not be like them: the conceit introduced deviations from nature, which were afterwards carried to ſuch an exceſs, that hardly any objects truly rural were left within the encloſure, and the view of thoſe without was generally excluded. The firſt ſtep, therefore, towards a reformation, was by opening the garden to the country, and that immediately led to aſſimilating them; but ſtill the idea of a ſpot appropriated to pleaſure only prevailed, and one of the lateſt improvements has been to blend the uſeful with the agreeable; even the ornamented farm was prior in time to the more rural; and we have at laſt returned to ſimplicity by force of refinement.

Of a Paſtoral Farm.

The ideas of paſtoral poetry ſeem now to be the ſtandard of that ſimplicity; and a place conformable to them is deemed a farm in its utmoſt purity. An alluſion to them evidently enters into the deſign of the leaſowes, in Shropſhire, between Birmingham and Stourbridge, where they appear ſo lovely as to endear the memory of their author; and juſtify the reputation of Mr. Shenſtone, who inhabited, made, and celebrated the place: it is a perfect picture of his mind, ſimple, elegant, and amiable; and will always ſuggeſt a doubt, whether the ſpot inſpired his verſe, or whether, in the ſcenes which he formed, he only realized the paſtoral images which abound in his ſongs. The whole is in the ſame taſte, yet full of variety; and, except in two or three trifles, every part is rural and natural. It is literally a grazing farm lying round the houſe; and a walk, as unaffected and as unadorned as a common field path, is conducted through the ſeveral encloſures. But for a detail of the plan and ſcenery, as illuſtrative of the preſent ſubject, the reader is referred to the particular deſcription of the Leaſowes publiſhed by the late Mr. Dodſley. We ſhall only take notice of one or two circumſtances independent on the general delineation.

The art with which the diviſions between the fields are diverſified is one of them. Even the hedges are diſtinguiſhed from each other: a common quickſet fence is in one place the ſeparation; in another, it is a lofty hedge row, thick from the top to the bottom; in a third, it is a continued range of trees, with all their ſtems clear, and the light appearing in the intervals between their boughs, and the buſhes beneath them; in others, theſe lines of trees are broken, a few groupes only being left at different diſtances; and ſometimes a wood, a grove, a coppice, or a thicket, is the apparent boundary, and by them both the ſhape, and the ſtyle of the encloſures are varied.

The inſcriptions, which abound in the place, are another ſtriking peculiarity: they are well known and juſtly admired; and the elegance of the poetry, and the aptneſs of the quotations, atone for their length and their number. But, in general, inſcriptions pleaſe no more than once; the utmoſt they can pretend to, except when their alluſions are emblematical, is to point out the beauties, or deſcribe the effects, of the ſpots they belong to; but thoſe beauties and thoſe effects muſt be very faint, which ſtand in need of the aſſiſtance. Inſcriptions, however, to commemorate a departed friend, are evidently exempt from the cenſure; the monuments would be unintelligible without them; and an urn, in a lonely grove, or in the midſt of a field, is a favourite embelliſhment at the Leaſowes: they are indeed among the principal ornaments of the place; for the buildings are moſtly mere ſeats, or little root-houſes; a ruin of a priory is the largeſt, and that has no peculiar beauty to recommend it: but a multiplicity of objects are unneceſſary in the farm; the country it commands is full of them; and every natural advantage of the place within itſelf has been diſcovered, applied, contraſted, and carried to the utmoſt perfection, in the pureſt taſte, and with inexhauſtible fancy.

An ancient Farm.

In ſuch an aſſortment, the more open and poliſhed ſcenes will generally be given to the Arcadian ſhepherd; and thoſe in a lower degree of cultivation, will be thought more conformable to the manners of the ancient Britiſh yeomanry.

The paſtures ſhould rather border on a waſte or a common: if large, they may be broken by ſtraggling buſhes, thickets, or coppices; and the ſcattered trees ſhould be beſet with brambles and briars. All theſe are circumſtances which improve the beauty of the place; yet appear to be only remains of the wild, not intended for embelliſhment. Theſe will ſufficiently break the ſameneſs of the ſpace; and tillage does not furniſh a more pleaſing ſcene, than ſuch a ſpace ſo broken, if the extent be moderate, and the boundary beautiful.

As much wood is eſſential to the character, a ſpot may eaſily be found, where turrets riſing above the covert, or ſome arches ſeen within it, may have the reſemblance of a caſtle or an abbey. The partial concealment is almoſt neceſſary to both; for to accord with the age, the buildings muſt ſeem to be entire; the ruins of them belong to later days: the diſguiſe is, however, advantageous to them as objects; none can be imagined more picturesque, than a tower boſomed in trees, or a cloyſter appearing between the ſtems and the branches. But the ſuperſtitions of the times furniſh other objects, which are more within compaſs: hermitages were then real; ſolitary chapels were common; many of the ſprings of the country being deemed holy wells, were diſtinguiſhed by little gothic domes built over them; and every hamlet had its croſs; even this, when perfect, ſet on a little ruſtic pillar, and that raiſed upon a baſe of circular ſteps, may in ſome ſcenes be conſiderable: if a ſituation can be found for a maypole, whence it would not obtrude itſelf on every view, that alſo might not be improper; and an ancient church, however unwelcome it may be when it breaks into the deſign of a park or a garden, in ſuch a farm as this would be a fortunate accident: nor would the old yew in the church yard be indifferent; it would be a memorial of the times when it was uſeful.

Of a ſimple Farm.

A part may alſo be free from either of theſe imitative characters, and laid out in a common ſimple farm. Some of the greateſt beauties of nature are to be found in the fields, and attend an ordinary ſtate of cultivation: wood and water may there be exhibited in ſeveral forms and diſpoſitions; we may enlarge or divide the incloſures, and give them ſuch ſhapes and boundaries as we pleaſe; every one may be an agreeable ſpot; together, they may compoſe beautiful views; the arable, the paſture, and the mead may ſucceed one another; and now and then a little wild may be intermixed without impropriety; every beauty, in ſhort, which is not unuſual in an incloſed country, whether it ariſe from neglect or improvement, is here in its place.

The buildings, alſo, which are frequent in ſuch a country, are often beautiful objects; the church and the manſion are conſiderable; the farm-yard itſelf, if an advantageous ſituation be choſen for it; if the ricks, and the barns, and the out-houſes, are ranged with any deſign to form them into groupes, and if they are properly blended with trees, may be made a picturesque compoſition. Many of them may be detached from the groupe, and diſperſed about the grounds: the dove-cote, or the dairy, may be ſeparated from the reſt; they may be elegant in their forms, and placed wherever they will have the beſt effect. Among ſo many buildings, ſome may be converted to other purpoſes than their conſtruction denotes; and, whatever be their exterior, may within be made agreeable retreats, for refreſhment, indulgence, or ſhelter. With ſuch opportunities of improvement, even to decoration within itſelf, and with advantages of proſpect into the country about it, a ſimple farm may undoubtedly be delightful. It will be particularly acceptable to the owner, if it be cloſe to his park or his garden: the objects which conſtantly remind him of his rank, impoſe a kind of conſtraint; and he feels himſelf relieved, by retiring ſometimes from the ſplendor of a ſeat into the ſimplicity of a farm: it is more than a variety of ſcene; it is a temporary change of ſituation in life, which has all the charms of novelty, eaſe, and tranquility, to recommend it. A place therefore, can hardly be deemed perfect, which is not provided with ſuch a retreat.

An ornamented Farm.

A ſenſe of the propriety of ſuch improvements about a ſeat joined to a taſte for the more ſimple delights of the country, probably ſuggeſted the idea of an ornamented farm, as the means of bringing every rural circumſtance within the verge of a garden. This idea has been partially executed very often; but no where, perhaps, ſo completely, and to ſuch an extent, as at Woburn farm. The place contains 150 acres; of which near 35 are adorned to the higheſt degree; of the reſt, about two thirds are in paſture, and the remainder is in tillage. The decorations are, however, communicated to every part; for they are diſpoſed along the ſides of a walk, which, with its appendages, forms a broad belt round the grazing-grounds; and is continued, though on a more contracted ſcale, through the arable. This walk is properly garden; all within it is farm; the whole lies on the two ſides of a hill, and on a flat at the foot of it; the flat is divided into corn-fields; the paſtures occupy the hill; they are ſurrounded by the walk, and croſſed by a communication carried along the brow, which is alſo richly dreſſed, and which divides them into two lawns, each completely encompaſſed with garden.

Theſe are in themſelves delightful; the ground in both lies beautifully; they are diverſified with clumps and ſingle trees; and the buildings in the walk ſeem to belong to them. On the top of the hill is a large octagon ſtructure; and, not far from it, the ruin of a chapel. To one of the lawns the ruin appears, on the brow of a gentle aſcent, backed and grouped with wood; other objects of leſs conſequence, little ſeats, alcoves, and bridges, continually occur. The buildings are not, however, the only ornaments of the walk; it is ſhut out from the country, for a conſiderable length of the way, by a thick and lofty hedge-row, which is enriched with woodbine, jeſſamine, and every odoriferous plant whoſe tendrils will entwine with the thicket. A path, generally of ſand or gravel, is conducted in a waving line ſometimes cloſe under the hedge, ſometimes at a little diſtance from it; and the turf on either hand is diverſified with little groupes of ſhrubs, of firs, or the ſmalleſt trees, and often with beds of flowers; theſe are rather too profuſely ſtrewed, and hurt the eye by their littleneſſes; but then they repleniſh the air with their perfumes, and every gale is full of fragrancy. In ſome parts, however, the decoration is more chaſte; and the walk is carried between larger lumps of evergreens, thickets of deciduous ſhrubs, or ſtill more conſiderably open plantations. In one place it is entirely ſimple, without any appendages, any gravel, or any ſunk fence to ſeparate it from the lawn; and is diſtinguiſhed only by the richneſs of its verdure, and the nicety of its preſervation. In the arable part it is alſo of green ſward, following the direction of the hedges about the ſeveral incloſures; theſe hedges are ſometimes thickened with flowering ſhrubs; and in every corner or vacant ſpace, is a roſary, a cloſe or an open clump, or a bed of flowers; but if the parterre has been rifled for the embelliſhment of the fields, the country has on the other hand been ſearched for plants new in a garden; and the ſhrubs and the flowers which uſed to be deemed peculiar to the one, have been liberally transferred to the other; while their number ſeems multiplied by their arrangement in ſo many and ſuch different diſpoſitions. A more moderate uſe of them would, however, have been better; and the variety more pleaſing, had it been leſs licentious.

But the exceſs is only in the borders of the walk; the ſcenes through which it leads are truly elegant, every where rich, and always agreeable. A peculiar cheerfulneſs overſpreads both the lawns, ariſing from the number and the ſplendor of the objects with which they abound, the lightneſs of the buildings, the inequalities of the ground, and the varieties of the plantations. The clumps and the groves, though ſeparately ſmall, are often maſſed by the perſpective, and gathered into conſiderable groupes, which are beautiful in their forms, their tints, and their poſitions. The brow of the hill commands two lovely proſpects; the one gay and extenſive, over a fertile plain, watered by the Thames, and broken by St. Anne's Hill and Windſor Caſtle; a large mead, of the moſt luxuriant verdure, lies juſt below the eye, ſpreading to the banks of the river; and beyond it the country is full of farms, villas, and villages, and every mark of opulence and cultivation.

With the beauties which enliven a garden are every where intermixed many properties of a farm; both the lawns are paſtured; and the lowings of the herds, the bleating of the ſheep, and the tinklings of the bell-wedder, reſound through all the plantations; even the clucking of poultry is not omitted; for a menagerie of a very ſimple deſign is placed near the Gothic building; a ſmall ſerpentine river is provided for the water-fowl; while the others ſtray among the flowering ſhrubs on the banks, or ſtraggle about the neighbouring lawn: and the corn-fields are the ſubjects of every rural employment, which arable land from ſeed-time to harveſt can furniſh. But though ſo many of the circumſtances occur, the ſimplicity of a farm is wanting; that idea is loſt in ſuch a profuſion of ornament; a ruſticity of character cannot be preſerved amidſt all the elegant decorations which may be laviſhed on a garden.

FARMER. He that rents a farm or is leſſee thereof. Alſo generally every leſſee for life, years, or at will, is called a farmer.

FARRIER, one whoſe employment is to ſhoe horſes, and cure them when diſeaſed or lame.

FARRIERY, the art of curing the diſeaſes of horſes.

SYSTEM OF FARRIERY.

THE practice of this uſeful art has been too long, almoſt entirely, confined to a ſet of men, totally ignorant of anatomy and the general principles of medicine. It is not therefore ſurpriſing that their preſcriptions ſhould be as abſurd as the reaſons they give for adminiſtering them. It cannot indeed be expected that farriers who are almoſt univerſally illiterate men ſhould make any real progreſs in their profeſſion. They preſcribe draughts, they rowel, cauterize, &c. without being able to give any other reaſon for their practice, than that their fathers did ſo before them. How can ſuch men deduce the cauſe of a diſeaſe from its ſymptoms, or form a rational method of cure, when they are equally ignorant of the cauſes of diſeaſes and the operation of medicines? The wretched ſtate of this uſeful art, eſpecially in the country, has determined us to ſelect from the moſt approved authors, ſuch a ſyſtem of practice as ſeems to be formed on rational principles: this we hope will be a ſufficient apology for being rather copious upon this ſubject.

Previous to treating on the diſeaſes incidental to horſes, and the methods of cure, we ſhall introduce a deſcription of the Oſteology and Myology of that noble animal, which will be compriſed in ſix plates. As we have ſpared neither pains nor expence, to illuſtrate this Syſtem, as well as every other we have hitherto undertaken to diſcuſs, we preſume it will appear that we have not been wanting in any inſtance to merit public ſanction, or render our work conducive to the attainment of univerſal Science.

PART I.

THE ANATOMY OF THE HORSE,

Including a particular Deſcription of the BONES, CARTILAGES, MUSCLES, FASCIAS, LIGAMENTS, NERVES, ARTERIES, VEINS, and GLANDS, all done from Nature.

PLATE I. *Figure* I. — SIDE VIEW.

Bones in the Head.

abcdefg, The os frontis, or forehead bone; *c* a ſuture which joins the frontal bone with the zygomatic, or jugal proceſs of the temporal bone; *e* the coronal ſuture.

hik, The vertical, or parietal bone; *i* a ſquamoſe ſuture, common to the parietal bone with the temporal bone; *k* the lambdoid ſuture, common to the parietal bone with the occipital bone.

lnoppq, The occipital bone; *l* the occipital protuberance, which in this animal is very large, together with the internal ſpine, or protuberance, which, directly oppoſite to this, makes a ſtrong body of bone in this place; *p* the condyloid proceſs, which is incruſted with a ſmooth cartilage.

rstuwx, Os temporis, or temporal bone; *r* the zygomatic, or jugal proceſs of the temporal bone; *t* the part which articulates with the lower jaw bone; *uw* a part which, in young horſes, may be eaſily divided, but afterwards becomes firmly united; it is diſtinguiſhed by the name of os petroſa, or apophyſis petroſa; *u* the mammillary proceſs; *w* the bony meatus, or entrance of the ear; *x* a ſuture common to the cheek bone, with the zygomatic proceſs of the temporal bone. *yz*, The orbitary portion of the bone of the palate. 1, Os unguis. 7, Os jugale, or cheek bone. 15, Os maxillæ ſuperioris, or the upper jaw bone. 16, Os naſi. 17, 18, 19, 20, The lower mandible or jaw bone; 17, at ſeventeen expreſſed in the plate, are marked roughneſſes, from which ariſe the tendinous parts of the maſſeter; 19, 19, the coronal or acute proceſs; 20, its condyle or head, that is joined with the temporal bone. 21, A moveable cartilaginous plate which is interpoſed in the articulation of the lower jaw.

The Vertebræ of the Neck.

AÆE *abbcde*, The atlas or uppermoſt vertebra: AÆ the poſterior and ſuperior part of the left ſide of this vertebra, which articulates with the condyloid proceſs of the occipital bone; A the anterior and ſuperior part of the right ſide of the atlas, which articulates with the occipital bone as a large tubercle on the anterior part of this vertebra; *b* the two tranſverſe proceſſes; *c* the protuberance, tubercle, or inequality on the poſterior part of this vertebra, which ſeems to be in the place of a ſpinal apophyſis; *d* the poſterior, and inferior part of the right ſide of this vertebra, which articulates with the ſecond vertebra; *e* the tranſverſe hole through which a nerve and blood-veſſels paſs.

fghiklmn, 12. The epiſtrophæus or ſecond vertebra of the neck; *f* the inferior part of the body which receives and is ſuſtained by the third vertebra of the neck: *g* the ſuperior part of its body, which is received by and ſuſtains the atlas or firſt vertebra of the neck; *h* the anterior protuberance of the body of this vertebra; *i* the tranſverſe proceſs; *k* the ſpinal proceſs; *l* the lower oblique proceſs on the right ſide, which is covered with a ſmooth cartilage within the dotted lines; *m* the lower oblique proceſs on the left ſide; at 1 is a hole where the vertebral artery goes in and comes out at 2, called the tranſverſe hole.

opqrstuwxy, The third vertebra of the neck; *o* the anterior protuberance of the body of this vertebra; *p* is the ſuperior part of the body of this vertebra, which is received into the inferior part of the body of the ſecond vertebra; and *q* is the inferior which receives the ſuperior part of the body of the fourth vertebra; *r* the tranſverſe proceſs; *s* the right uppor oblique proceſs; *t* the right lower oblique proceſs; *u* the ſpinal proceſs; *w* the tranſverſe holes through which the vertebral arteries and veins of the neck paſs; *x*, the left upper oblique proceſs; *y* the left lower oblique proceſs.

A Continuation of the Bones of the Spine from the Neck.

1 *abcdef*G, The firſt or uppermoſt vertebra of the back; *a*, the body; *b*, the tranſverſe proceſs; *c*, the upper oblique proceſs, *d*, the lower oblique proceſs; *e*, the ſpinal proceſs; *f*, the lower oblique proceſs of the left ſide, ſeen through the large hole which contains the medulla ſpinalis; G, the ligament interpoſed betwixt the bodies of the firſt and ſecond vertebra of the back. 2 5 6 7 8 9 10 11 12 13 14 15 16 17 18, Are vertebræ of the back, the firſt vertebra of the back having been explained as above, and the ſame letters of reference, applied to ſimilar ſurfaces and foramina, &c. as likewiſe to the ſix vertebra of the loins, a further explanation is unneceſſary. ABCDEF, The ſix vertebræ of the loins. *ghiklm*, The os ſacrum or great bone of the ſpine; *g*, the anterior part or body of this bone which, in young animals, is divided into as many bodies as there are ſpines in this bone, it being then like five vertebræ, whoſe tranſverſe proceſſes make the unequal rough part *h*, of this bone; *i*, the five ſpines; *k*, three inferior and anterior holes, which tranſmit the nerves on each ſide. *nopq*, The firſt bone of the coccyx or tail; *n*, the body; *o*, the tranſverſe proceſs; *p*, the upper oblique proceſs, which articulates with the os ſacrum; there is no lower oblique proceſs; *q*, the ſpine; *r*, the ligament interpoſed betwixt the bodies of the firſt and ſecond bone of the tail, tying them together. There are 18 bones in the tail.

Bones in the Thorax and Shulder-blades.

ab. The ſternum or breaſt bone, of which the parts *a* are bony, the reſt, *b*, is chiefly cartilaginous, or ligamentous, by which the bony parts are connected together. 1 *ce*, The firſt rib; *c*, the head by which it is articulated with the tranſverſe proceſs of the firſt or uppermoſt vertebra of the back; *e*, the cartilaginous end by which it is continued to the ſternum. This explanation will ſerve for the reſt of the ribs, but it is to be obſerved, that the eight ſuperior ribs only are connected to the ſternum, the others are called falſe ribs. 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18, Shew the external ſide of the ribs on the right ſide, and internal on the left ſide. *fg*, The inner ſide of the left ſcapula or ſhoulder-blade. *hiklmnopq*, The right ſcapula; *h*, its neck; *i*, its ſpine; *k*, the coracoid apophyſis, or epiphyſis; *l*, its inferior coſta; *m*, its ſuprior coſta; *n*, its baſis; *o*, foſſa ſub-ſpinalis; *p*, foſſa ſupra-ſpinalis; *q*, a cartilaginous continuation of the ſcapula.

Bones in the Right Upper Limb.

*abbhik*K*lm*, The humerus *or bone of the arm*; *b*, denotes a protuberance into which the teres minor is inſerted; *h*, the part of the head which is joined to the cavity of the ſcapula, covered with a ſmooth cartilaginous cruſt; *i*, the external condyle of the lower head; *k*K, the head covered with a ſmooth cartilage with which the radius is articulated; K, the double articular eminence; *l*, the anterior foſſula or ſinus that receives the upper head of the radius when the cubit is bent as much as it can be; *m*, the poſterior ſinus which receives the olecranon of the ulna when the cubit is extended as much as it can be.

nopqr, The radius; *no*, the upper head; *pqr*, the lower head of this bone; *p*, denotes a ſinus or groove through which goes the tendon of the extenſor carpi radialis; *q*, a ſinus through which goes the tendon of the extenſor degitorum communis; *r*, a ſinus through which goes the tendon which is analagous to the tendon of the extenſor minimi digiti.

sttuu, The ulna; *s*, the olecranon or elbow; *tt*, the part which articulates with the humerus; *uu*, the lower part, which is very ſmall, and in aged horſes becomes one bone with the radius.

wxyz, 23, The bones of the carpus; *w*, os ſcaphoides or naviculare; *x*, os lunare; *y*, os cuneiforme; *z*, os piſiforme or orbiculare; (the bone called trapezium, which articulates with the thumb is not in the horſe;) 2, os magnum or the great round-headed bone of the wriſt; 3, the unciform or hook-like bone of the wriſt. 4 5 6 7, The metacarpal bones in this animal called the ſhank-bones, of which that marked 4 5, is equal to two of the metacarpal bones joined together, viz. that of the middle finger, and that of the ring finger; 4, the upper head by which it articulates with the carpus; 5, the lower head, in this place incruſted with a ſmooth cartilage; 6 7, an imperfect metacarpal bone in the place of that in the human ſkeleton which belongs to the little finger; 6, the upper head by which it articulates with the unciform bone of the carpus; 7, the lower head, which is very ſmall, and (the bones of the little finger being wanting) forms no articulation. 10 11, Two bones which are always to be found in this joint; ſuch bones are called ſeſamoid bones in the human ſkeleton. 12 13, A bone which is equal to the bones of the phalanges of the middle and ring finger in the human ſkeleton; in a horſe this is called the great paſtern. 14 15, The bone of the ſecond phalanx of the fingers, or the little paſtern or coronary bone. 16, The bone of the third phalanx, in a horſe called the coffin bone.

In the Pelvis.

abcdefghikl, The right os innominatum or baſon bone including three others; *abcd*, the os ilium, hip, or flank bone; *bc*, the ſpine; *b*, the anterior part of the ſpine; *c*, the poſterior part; *efg*, the os iſchium, or hich bone; *e*, the acute proceſs; *f*, the tubercle of the iſchium; *gg*, the poſterior notch for the paſſage of the internal obturator muſcle; *h i*, the os pubis; *i*, the ſpine or ridge of the os pubis; *k*, the great foramen of the iſchium and pubis; *l*, the external margin of the acetabulum.

In the lower Limbs.

abcdehi, The right femur or thigh bone; *a*, the body or middle of this bone; *bcde*, the upper extremity, of which, *b*, is the neck; *c*, the head incruſted with a ſmooth cartilage where it is jointed into the acetabulum; *d*, the great trochanter or ſpoke; *e*, the leſs trochanter or ſpoke; *hi*, the lower extremity; *h*, the outer condyle of the lower head, which at *i* is covered with a ſmooth cartilaginous cruſt. *q r*, The patellæ or knee pan bones; *r*, that part which is covered with a ſmooth cartilaginous cruſt which forms part of the joint at the knee. *ſ*, The inner ſimilunar cartilages which are interpoſed in the joints of the knees. *t*, The outer ſimiluna cartilages in the joints of the knees. *uvwxy*, The tibiæ or greater bones of the legs; *u*, the upper head; *v*, that part of the upper head which, belonging to the joint of the knee, is covered with a ſmooth cartilaginous cruſt; *w*, a protuberance in which terminate the anterior ligaments which come from the patella and tie it to the tibia; *y*, the lower head of the right tibia; *z* the lower head of the left tibia. 1 2 1, The fibulæ or ſmall bones of the legs; 1, the upper head; 2, the lower extremity which ends here almoſt in a point. 3 4 5 6, The aſtragali or cockal bones; 4 5, the part which forms the juncture with the bone of the leg covered with a ſmooth cartilaginous cruſt. 7 8 9, The calcanei or heel-bones; 8, the projecting part that ſuſtains the aſtragalus; 9 the tubercle into which is inſerted the tendon of the gemellus, and to which the tendon of the plantaris is attached by ligaments. 10, The cubical bone of the tarſus or ancle. 11, The navicular bones of the tarſus. 12, The middle cuneiform bones of the tarſus. 13, The leſs cuneiform bone of the tarſus. N. B. What are called the great cuneiform bones of the tarſus in the human ſkeleton are (as well as the bones of the great toe) wanting in this animal.

14 15 16 17 18 19, The bones of the metatarſus or inſtep; 14 15, a bone which is equal to the metatarſal bones of the ſecond and third little toes both together in the human ſkeleton; 14 the upper head which articulates with the three lower bones of the tarſus; 15 the lower head, in this place covered with a ſmooth cartilaginous cruſt, where it articulates with the upper head of the bone of the firſt phalanx or order of the ſmall toes; 16 17 an imperfect metatarſal bone in the place of that which, in the human ſkeleton, belongs to the little toe; 16 the upper head, by which it articulates with the cubical bone of the tarſus; 17, the lower head which is very ſmall, and (the bones of the little toe being wanting) forms no articulation; 18 19, an imperfect metatarſal bone in the place of that which, in the human ſkeleton, belongs to the firſt of the ſmall toes; 18 the upper head by which it articulates with the leſs cuneiform bone of the tarſus; 19, the lower head which is very ſmall, and (the bones of the firſt of the ſmall toes being wanting) forms no articulation.

20 21, Bones which are always to be found in theſe joints, two in each, ſuch are called ſeſamoid bones in the human ſkeleton; 22 23 24, The bones which are in the places of the three phalanges, or orders of bones of the ſmall toes in the human ſkeleton: with farriers the firſt are called the great paſterns, the ſecond the little paſterns, or coronary bones, the third the coffin bones. 25 25, Seſamoid bones lying over the poſterior parts of the articulations of the coffin bones, with the coronary bones.

PLATE I. *Figure 2.* — FRONT VIEW.

Bones in the Head.

A, The os frontis, or forehead bone divided into two by the continuation A of the ſagittal or longitudinal ſuture. *h i k l*, The vertical or parietal bones; *i*, the ſquamoſe or ſcale-like ſutures, which are formed by the conjunction of the parietal with the temporal bones; *k*, the lambdoide ſuture formed by the conjunction of the parietal bones with the occipital bone; *l*, the ſagittal or longitudinal ſuture, formed by the union of the two parietal bones. *m*, The occipital bone; *m*, the large protuberance which is marked *l* in table the firſt, and which, in a horſe, is called the noſe bone. *op q*, The temporal bones; *o*, the zygomatic or jugal proceſſes of the temporal bones. *s*, The oſſa naſi, or bones of the noſe. *w*, The oſſa unguis. 1, The oſſa jugalia, or cheek bones. 4 5 6 7 8, The oſſa maxillaria, or great bones of the upper jaws; 5 5, the foramina, or holes of the channels, which paſs along the bottoms of the orbits of the eyes; 6 6, parts of the upper jaw bones which belong to the bottoms of the noſtrils and arch of the palate; 7 8 9, the anterior parts, which are joined to the poſterior parts of theſe bones by ſutures marked 14 in table the firſt of the ſkeleton; 7, parts belonging to the bottoms of the noſtrils and to the arch of the palate. 10 11 12 13 14 15, The ſix dentes inciſores, cutting teeth, or nippers, of the upper jaw. 16 18, Maxilla inferior, the lower mandible or jaw bone.

In the Spine.

aa, The tranſverſe proceſſes of the atlas or uppermoſt vertebra of the neck. 1 *d*, The tranſverſe proceſs of the fifth vertebra of the neck. 2 *bcdefg*, The ſixth vertebra of the neck; *b*, the anterior and lower part of the body of this vertebra, which receives the ſuperior part of the body of the ſeventh vertebra; *c*, the ſuperior part of the body of this vertebra, which is received by the fourth vertebra; *d*, the tranſverſe proceſs; *e*, the anterior oblique proceſs which is peculiar to this vertebra, and marked *z* & in table the firſt; *f*, the upper oblique proceſs; *g*, the lower oblique proceſs. 3 *bcdfg*, The ſeventh or laſt vertebra of the neck; 3, the body; *b*, the anterior protuberance of the body of this vertebra; *c*, the head or upper part of the body of this vertebra, which articulates with the vertebra above it; *d*, the tranſverſe proceſs; *f*, the upper oblique proceſs; *g*, the lower oblique proceſs.

h i k, &c. *l* & *c*, The vertebræ of the back; *h*, is placed on the body of the vertebræ, and explains the ſituation of the bodies of the 4 vertebræ, behind which are too ſmall to admit of letters; *k*, the tranſverſe proceſs, three more are ſeen behind; *l*, the ſpinal proceſs, five more are ſeen behind.

1 *mnop*, The firſt vertebra of the loins; *m*, the upper oblique proceſs; *n*, the lower oblique proceſs; *p*, the tranſverſe proceſs; *o*, the ſpinal proceſs. The ſame explanation will do for all thoſe of the loins. *qr*, The os ſacrum, or great bone of the ſpine; *q*, the upper oblique proceſs, by which it articulates with the lower oblique proceſs of the loweſt vertebra of the loins; *r*, the ſpinal proceſſes. *s*, The bones of the tail.

In the Thorax and Shoulder Blades.

ab, The ſternum, or breaſt bone, of which the parts *a* are bony, the reſt *b* is chiefly cartilaginous or ligamentous, and connects the bony parts together. C, The enſiform cartilage. 1 *cde*, The firſt rib on the right ſide; *c*, the head, by which it is articulated with the tranſverſe proceſs of the firſt or uppermoſt vertebra of the back; *d*, the anterior or former part of the ſaid head which is connected to the bodies of the ſeventh vertebra of the neck, and firſt of the back; *e*, the cartilaginous end by which it is continued to the ſternum. *fghiklmno*, *fghkkp*, the ſcapulæ, or ſhoulder blades; *f*, the neck; *g*, the ſpine; *h*, the coracoid or crow's-bill proceſs; *i*, the inferior coſta; *k*, the ſuperior coſta; *l*, the baſis; *m*, foſſa ſub-ſpinalis; *n*, foſſa ſupra-ſpinalis; *o*, a cartilaginous continuation of the baſis ſcapulæ; *p*, the internal and concave ſide of the left ſcapula.

In the Upper Limbs

abcdefghiklmn, The humeri, or bones of the arm; *b*, denotes a protuberance into which the teres minor is inſerted; *cdefgh*, the upper head; *cde*, three protuberances which form two ſinuſes or grooves, which are incruſted with a ſmooth cartilage; they ſerve to confine the heads of the biceps muſcle of the arm from ſliding ſideways, but ſuffer them eaſily to ſlide up and down; *h*, that part of the head which is covered with a ſmooth cartilaginous cruſt, and articulates with the ſcapula; *i*, the external condyle of the lower head; *kl*, the lower head covered with a ſmooth cartilage with which the radius is articulated; *k*, the round articular eminence; *l*, the double articular eminence; *m*, the anterior foſſula or ſinus that receives the upper head of the radius, when the cubit is bent as much as it can be; *n*, the internal condyle.

opq, The radii, or the radius of each arm; *o*, a protuberance in the upper head, into which the biceps and brachialis are inſerted: *p*, denotes a ſinus, or groove, in the lower head, through which goes the tendon of the extenſor carpi radialis; *q*, a ſinus, through which goes the tendon of the extenſor digitorum communis; *r*, a ſmooth cartilaginous incruſtation of the lower head, where it articulates with the bones of the carpus.

w x y, 1 2 3, The bones of the carpus; *w t*, os ſcaphoides, or naviculare; *t*, the part which articulates with the radius, covered with a ſmooth cartilaginous incruſtation; *x t*, os lunare, or the lunar bone of the carpus, or wriſt; *t*, the part incruſted with a ſmooth cartilage by which it articulates with the radius; *y*, the cuneiform or wedge-like bone of the carpus; 1 *u*, the trapezoid, cubical, or leaſt of the multangular bones of the carpus, at *u*, incruſted with a ſmooth cartilage for it's articulation with the navicular bone of the carpus; 2 *u*, os magnum, or the great round-headed bone of the wriſt; *u* the part which articulates with the os magnum and os lunare, incruſted with a ſmooth cartilage; 3 *u*, the unciform or hook-like bone of the wriſt, at *u* incruſted with a ſmooth cartilage, by which it articulates with the lunar and cuneiform bones of the carpus: theſe cartilaginous incruſtations do not appear in the left carpus, the joint being fully extended.

4 5 6 7 8 9, The metacarpal bones, called, in the ſkeleton of a horſe, the ſhank bones; 4 5, the ſhank bone which is equal to the metacarpal bone of the middle-finger, and that of the ring-finger both together; 4, the upper head; 5, the lower head, incruſted, in this place, with a ſmooth cartilage for it's articulation with the great paſtern or firſt phalanx of the fingers; 6 7, an imperfect metacarpal bone, in the place of that which, in the human ſkeleton, belongs to the little-finger; 6 the upper head by which it articulates with the unciform bone of the carpus; 7, the lower head which is very ſmall, and (the bones of the little-finger being wanting) forms no articulation; 8 9, an imperfect metacarpal bone in the place of that which, in the human ſkeleton, belongs to the index or firſt finger; 8 the upper head, by which it articulates with the trapezoid bone of the carpus; 9, the lower head, which is very ſmall, and (the bones of the firſt-finger being wanting) forms no articulation. 12 13, Bones which are equal to the bones of the firſt phalanges of the middle and ring-fingers in the human ſkeleton: in a horſe theſe are called the great paſterns. 14 15, Bones

of the ſecond phalanges; the little paſterns or coronary bones. 16, The bones of the third phalanges, or coffin bones.

In the Pelvis.

abcd, The innominata or baſon bones, including three others; *abc*, the os illium or flank bones; *b*, the anterior part of its ſpine; *c*, the poſterior part of its ſpine; *d*, part of the iſchion or hich bone, ſeen betwixt the ribs; *E*, part of the os pubis ſeen alſo betwixt the ribs.

In the lower Limbs.

abcde, *aff*, The thigh bones; *a*, the greater trochanter or ſpoke; *b*, the leſs trochanter; *c*, the protuberating part of the linea aſpera, into which the external glutæus is inſerted along with a part of the muſculus faſcia lata; *d*, the outer condyle; *e*, the inner condyle: *ff*, the anterior part of the lower head of the right femur. *g*, *g g*, The patellæ or knee-pan bones.

b, The outer ſemi-lunar cartilage in the joint of the knee.

iklm, *i m*, The tibiæ, or great bones of the legs; *kl*, the upper head; *k* a protuberance, into which is fixed the anterior ligaments of the patella; *l*, that part which belongs to the joint of the knee and is covered with a ſmooth cartilage; *m*, the lower head, which articulates with the bones of the tarſus. M, The fibula.

nop, The aſtragali, or cockal bones; *n o*, the part which forms the juncture with the bone of the leg, covered with a ſmooth cartilaginous cruſt. *q r*, The os calcis, or heel bone; *r*, the projecting part that ſuſtains the aſtragalus. *s*, The cuboid, or cubical bone of the tarſus. *t*, The navicular bones of the tarſus. *u*, The middle cuneiform bones of the tarſus. *w*, The ſmall cuneiform bone of the tarſus. *x y z &*, The metatarſal, or inſtep bones. 1, The great paſterns. 2, The little paſterns or coronary bones 3, The bones of the third phalanges, or coffin bones.

PLATE I. *Figure* 3. — BACK VIEW OF THE SKELETON.

Bones in the Head.

A That part of the os frontis which helps to form the orbit of the eye. *a b*, The occipital bone, of which *a b* is that which, in the ſkeleton of a horſe, is called the nole bone. *df*, The temporal bone; *d*, the zygomatic or jugal proceſs; *f*, the bony meatus or entrance of the ear. *g h* G, Oſſa palati; *g*, the orbitary part; *h*, the portia palatina, or part which compleats the arch of the palate. *iklmn*, Os ſphenoides; *i i*, denote roughneſſes into which the anterior recti muſcles of the head are inſerted; *m*, the pterygoid apophyſes; *l n*, *l n*, the large lateral proceſſes of the multiform, or ſphenoidal bone. *p q*, Os jugale, or cheek bone. *rstuw*, The oſſa maxillaria, or great bones of the upper jaw. *xy*, Os vomer; *y*, that part which forms the poſterior part of the ſeptum narium. 1, 2 z, Os ethmoides; 1, the part which helps to form the orbit; 2, the labyrinth of the noſtrils; *z*, conchæ narium ſuperiores. 3, Dentes molares, or grinding teeth of the upper jaw. 4, One of the canini of the upper jaw. 5, One of the dentes inciſores, cutting teeth, or nippers of the upper jaw. 678, Maxilla inferior, or the lower mandible, or jaw bone; 8 it's condyle or head, by which the mandible is articulated to the temporal bone. 9, Dentes inciſores, the cutting teeth, or nippers of the lower jaw.

In the Spine.

abcde, The atlas, or uppermoſt vertebra of the neck; *a*, the protuberance, tubercle, or inequality on the poſterior part of this vertebra, which ſeems to be in the place of a ſpinal apophyſis; *b*, the tranſverſe proceſs; *c*, the ſuperior and poſterior notch; *d*, the tranſverſe hole; *e*, a large tubercle on the anterior part of this vertebra.

fghikl, The epiſtrophæus, or ſecond vertebra of the neck; *f*, the ſpinal proceſs; at *g* the ſpine is divided into two, and continued to the lower oblique proceſſes; *h*, the lower oblique proceſſes; *i*, the tranſverſe proceſſes; *k*, the ſuperior part of it's body, which is received by, and ſuſtains the atlas; *l*, the tranſverſe hole.

klmnp, The third vertebra of the neck; *k*, the ſpinal proceſs; *ll*, the upper oblique proceſſes; *m m*, the lower oblique proceſſes; *n n*, the tranſverſe proceſſes; *p*, the internal ſide of the body of this vertebra.—This explanation will ſerve for thoſe of the neck which are below this; only it is to be obſerved, that *o* marks the upper part of the body of the fifth vertebra, where it articulates with the fourth at *p*; *r*, denotes the anterior oblique proceſs of the ſixth vertebra, and *q q*, thoſe parts of the oblique proceſſes which are incruſted with ſmooth cartilages.

r&c*s*&c*t*&c, The vertebræ of the back; *rr*&c, the ſpinal proceſſes; *ss*&c, the bodies; *tt* &c, the ligaments. *u* &c *w* &c *x* &c *yz* &c, The vertebræ of the loins; *uu*&c, the ſpinal proceſſes; *ww*, the bodies; *xx* &c, the tranſverſe proceſſes; *yy*, the ligaments interpoſed betwixt the bodies of the vertebræ, tying them to each other; *zz*&c, the openings betwixt the tranſverſe proceſſes through which the nerves come from the medulla ſpinalis.

1234&c. The os ſacrum, or great bone of the ſpine; 1, the rough part, compoſed of the tranſverſe proceſſes of this bone; 2 2, the ſpinal proceſſes; 3, the anterior part, which, in a young horſe, is divided into as many bodies as there are ſpines, betwixt which, in the parts 5, are bony lines that were formerly ligaments.

6, &c. 7, &c. 8, &c. 9, &c. The bones of the coccyx or tail; 66, &c. the tranſverſe proceſſes; 77, &c. the ſpinal proceſſes; 88 &c, the bodies; 99, the ligaments interpoſed betwixt the bodies of the bones of the tail.

In the Thorax and Shoulder-blades.

a, The ſternum. *b*, The enſiform cartilage. *c*, &c. *d*, &c. *e*, &c. *f*, &c. *g*, &c. The ribs; *c*, &c. the parts by which they articulate with the bodies of the vertebræ; *d*, &c. the cartilages by which they are continued to the ſternum, eight on each ſide; *e*, &c. the external ſide of the ribs; *ff*, &c. the internal ſide of the ribs; *gg*, &c. the cartilages of the falſe ribs which are ten on each ſide. *hikl*, The right ſcapula; *h*, it's ſpine; *ii*, it's baſis; *k*, a cartilaginous continuation of its baſis; *l*, it's foſſa ſubſpinalis. *m m n o*, The internal ſide of the left ſcapula; *n*, the coracoid proceſs, or a ſmall part of its neck.

In the Pelvis.

abcdefghi, A *bcfgh*, The innominata or baſon bones including three others; *a b c d*, the os ilium on the right ſide; *b c*, its ſpine; *d* a protuberance, from which ariſes the rectus muſcle of the leg; *ef*, the os iſchium or hich bone; *e*, the acute proceſs; *f*, the tubercle; *g*, the os pubis; *h*, the great foramen of the iſchium and pubis; *i*, the external margin of the acetabulum.

In the Upper Limbs.

abcd, A, The humeri or bones of the arm; *a b* the upper head; *b*, the part of the head which is joined to the cavity of the ſcapula, covered with a ſmooth cartilaginous cruſt; *d*, the external condyle of the lower head; A a ſmall part of the head of the right humerus. *efg*, *g*, The ulnæ; *e*, the olecranon; *f*, the part which articulates with the lower part of the ulna, which, in aged horſes, becomes one bone with the radius. *hiklmnop*, the radii; *h i*, the upper head of the radius; *klmno*, the lower head; *m*, the part which articulates with the os ſphenoides, or naviculare, incruſted with a ſmooth cartilage; *n*, the part which articulates with the os piſiforme or orbiculare, incruſted with a ſmooth cartilage.

P, *pqrstuwxyz*, The bones of the carpus; P os piſiforme or orbiculare; *p q*, os ſpenoides or naviculare; *p*, the part covered with a ſmooth cartilage for its articulation with the radius; *r*, os lunare; *s*, os cuneiforme; *t u*, os trapezium; *t*, the cartilaginous incruſtation by which it articulates with the os ſphenoides; *w x*, os magnum, or the great round-headed bone of the wriſt; *w*, the round head covered with a ſmooth cartilage for its articulation with the os lunare; *y z*, the unciform or hook like bone of the wriſt; *y*, the ſmooth cartilaginous incruſtation for its articulation with the cuneiform or wedge-like bones of the wriſt.

1234567, The metacarpal bones; 123, a bone which is equal to the metacarpal bones of the middle and ring-fingers, both together in the human ſkeleton.

8 9, Oſſa ſeſamoidea, two bones which are always to be found in this joint. 10, The bones of the firſt phalanges or order of bones in the fingers, in the horſe called the great paſterns. 11, The bones of the ſecond phalanges, called in the horſe, the little paſterns or coronary bones. 12, The bones of the third phalanges, or the coffin bones.

In the Lower Limbs.

abcddefghik, Oſſa femorum, or the thigh bones; *b*, the head, incruſted with a ſmooth cartilage for its articulation with the acetabulum; *c*, the leſs trochanter; *d d*, the great trochanter; *e*, a very prominent part of the linea aſpera, into which the external glutæus is inſerted along with part of the faſcia lata; *f*, a large foſſa or notch, out of and from the borders of which, the external head of the gemellus and the plantaris muſcles ariſe; *g*, a roughneſs from which ariſes the internal head of the gemellus; *h*, the outer condyle of the lower head, covered with a ſmooth cartilage; *i k*, the inner condyle, at *i* incruſted with a ſmooth cartilage.

l, The patellæ, or knee pan bones. *m*, The outer ſemi-lunar cartilages, which are interpoſed in the joints of the knees. *n*, The inner ſemi-lunar cartilages, which are interpoſed in the joints of the knees. *opqr*, The tibiæ, or great bones of the legs; *op*, the upper head; *r*, the lower head. *st*, The fibulæ, or ſmall bones of the legs; *s*, the upper head; *t*, the lower extremity which ends here almoſt in a point. *uwxxyz &*, 1, The bones of the tarſus. *uw*, The calcanei, or heel bones.

x, The aſtragali, or cockal bones. *y*, The cubical bones of the tarſus. *z*, The navicular bones of the tarſus. *&*, The middle cuneiform bones of the tarſus. 1, The leſs cuneiform bones of the tarſus. 234567, The bones of the metatarſus, or inſtep; 89, Oſſaſeſamoidea, they are bones which are always to be found in theſe joints, two in each; they ſerve to throw the bending tendons farther from the center of motion, and form a proper groove for them to ſlide in. 10 11 12, The bones which are in the places of the three phalanges or orders of bones in the human ſkeleton: with farriers the firſt are called the great paſterns; the ſecond the little paſterns or coronary bones; and the third the coffin bones.

PLATE II. *Figure* 1. — SIDE VIEW.

The External Muſcles, with the Ligaments, &c. As they are ſeen through the Membrana Carnoſa and Faſcia.

Muſles in the Head.

A, Epicranius, or muſcle of the ſcalp; *bcde*, The orbicular muſcle of the eye-lid; *e*, the origin of the fibres from the ligament by which the conjunction of the eye-lids, in the great canthus, is tied to the naſal part of the os unguis. *fg*, The corrugator of the eye-brow; *f*, its origin; at *g*, it is inſerted into the ſkin. *hik*, The elevator of the upper lip and corner of the mouth; *i k*, its oirgin from the epicranius; *p q*, The lateral dilator of the noſtril and upper lip. *r s t u w x*, Zygomaticus; *t*, its inſertion into the orbicularis of the mouth: *w x*, its origin from the orbicularis of the eye; it is a very thin muſcle. *z z*, & B, The orbicular muſcle of the mouth; 1 2, The depreſſor of the lower lip. 3 4, Part of the latiſſimus colli, which at 4, is inſerted into the lower jaw bone. 5, The elevators of the chin where they are inſerted into the ſkin, the fibres of which are intermixed with the fat of the chin. 6, The anterior dilator of the noſtril. 7, The tendon of the long naſal muſcle of the upper lip. 8, The tendon of the upper lip. 9, Septum narium.

Muſcles of the Outer Ear.

a, Retrahens; *c d h*, The ſuperior anterior muſcle through which is ſeen the origens; where it joins its fellow, having no origin fram the bone; *d*, its inſertion into the cartilage; *h*, a part of it which runs over the cartilage, and is inſerted near *h* into the outer ear. *g i*, Muſcles that run from the anterior cartilage *k*, to the external ear. *k*, The anterior cartilage of the outer ear. *l*, The lateral muſcle of the anterior cartilage of the outer ear; it ariſes above the orbit of the eye, and is inſerted into the anterior cartilage of the outer ear. *m*, A muſcle ariſing under *l*, which is inſerted at the inferior angle of the opening of the ear, anteriorly, with *i*. *n o*, The lateral depreſſor of the outer ear, ariſing at *n*, from the quadratus colli it is inſerted, cloſe by the muſcle *m*, into the lower angle of the opening of the ear poſteriorly. *p*, The outer ear.

In the Neck.

3 4, *a b c d*, Latiſſimus colli, or quadratus of the neck; *b*, its origin from the ſternum, a little below the top; 4, its inſertion into the lower jaw bone; *f g l*, Levator humeri proprius; *g*, that part which ariſes tendinous from the proceſſus maſtoideus; *l*, the portion that ariſes from the tranſverſe proceſſes of the four uppermoſt vertebræ of the neck near their extremities; its origin is the ſame with the angularis called levator ſcapulæ proprius in the human body; *o p x*, The upper part of the trapezius; *o p*, the origin of the fleſhy part; the external faſcia runs over the levator humeri proprius, and is attached to the edge of the quadratus colli, the internal faſcia goes on the internal ſurface of the levator humeri proprius; *x* the origin of the trapezius from the ligament of the neck. *y z &*, The inferior part of the trapezius.

In the Shoulder and Trunk.

abcdefghiklmnopqrs, Membrana carnoſa; *a*, the thickeſt fleſhy part; *b*, the thick fleſhy parts running upon the extenſors of the cubit, becomes tendinous at *c*, and goes to be inſerted with the latiſſimus dorſi and teres major into the humerus; *dd*, ſome of the thick fleſhy part going over the muſcles of the cubit and tending towards the cubit, forms the membranous tendon *q*; *f*, a fleſhy part which runs into the dublicature of this membrane, &c. as it goes towards the thigh; at *g*, it is fleſhy, but little more than a membrane, being very thin; *h*, a membranous part which runs over the penis; *i*, the tendinous membranous part which runs over the loins; *k*, the membranous part which helps to form the duplicature; *l*, a feint appearance of the outline of the latiſſimus dorſi; the part *m* is about as thick as the part *n*, and the latiſſimus dorſi both together; *o*, the part where the carnous fibres of the ſuperior portion of this muſcle.

t u w x y, Pectoralis; *t*, it's origin from the aponeuroſis of the external oblique muſcle of the abdomen.

Muſcles, &c. in the upper Limb or Extremity, as they appear under the Membrana-carnoſa.

a b, Extenſor carpi-radialis; *a* the fleſhy part; *b*, the tendon, *d e f g h*, Extenſor ulnaris & digitorum communis; *d*, the fleſhy part ſhewing itſelf under the membrane *e e*; *f g*, the tendon which goes under the ligament at *e*, and giving a ſlip *f*, to the tendon *i i*, of the extenſor, analagous to the extenſor minimi digiti; *h*, the tendon, ſending fibres laterally over the ligament *m*, *i*, Extenſor minimi digiti, to which the carnous membrane is attached at *i k*, and ſends tendinous fibres over it in the direction as marked. *n*, The bone, which is an imperfect metacarpal bone to which this membrane is attached. *o*, A ſort of ſpungy, fatty ſubſtance, probably a production of the membrana adipoſa, lying over the protuberating part of this joint to preſerve the bending tendons from bruiſes when this part touches the ground, &c. *p q*, Flexor carpi ulnaris; at *p*, the fleſhy fibres appear under the membrane, and alſo under its own tendinous ſurface. R *r*, Flexor digitorum profundus; R, the fleſhy part appearing under the tendinous ſurface of this muſcle as well as the carnous membrane. *s*, The tendon of the ſublimis, T *t*, The inter-muſcular ligament to the part of which the carnous membrane has ſome adheſion. *u*, Marks the ligaments ariſing at *u*, from the orbicular bone and running obliquely downwards and forwards. *x x*, Vena plantaris externa. &, The hoof.

In the Lower or Poſterior Limb.

a b c d e f g h i k K *l m n o p q r s t u w x y z &*, Faſcia lata, and muſculus faciæ latæ, with the membrana carnoſa, and expanſions of the muſcles; *a*, the part which is a continuation of the tendon of the latiſſimus dorſi, *b*, the origin of the muſculus faſciæ latæ from the ſpine of ilium. K, The patella with it's external lateral ligament. *l*, The extenſor longus digitorum; *m* peroneus; *n*, flexor digitorum pedis; *o*, Gemellus. *s*, The tendon of the extenſor digiti. *t*, The tendon of the flexors. *u*, The interoſſeus, &c, *w*, Veins ariſing from under the hoof, called venæ plantares, they run into the vena tibialis poſterior. *y*, A ligament ſent off by the interoſſeus, &c. A, The hoof.

Muſcles, &c. protuberating under the Membrana Carnoſa in the Left Upper Limb, viz. on the Cubit, Carpus, Metacarpus, and Extremity of the Limb.

a b, Extenſor carpi radialis; *c*, The tendon of the muſcle, which is analogous to the extenſor of the thumb. *d*, Biceps cubiti. *e*, Pectoralis, *f*, Flexor digitorum. *g*, Flexor carpi radialis. *h*, Sublimis. *i*, Profundus. *k*, The tendon of the extenſor ulnaris & digitorum communis. *l*, A ſort of ſpungy, fatty ſubſtance, probably a production of the membrana adipoſa. *m*, vena cephalica. *n*, Vena plantaris interna. *o*, Nervus plantaris internus. *p*, Interoſſeus, &c. *q*, A ligament coming from the interoſſeus and inſerted into the extending tendon. *r*, The hoof.

PLATE III. *Figure* I. — SIDE VIEW.

A full and compleat View of the External Muſcles, Ligaments, &c. the Membrana Carnoſa and Faſcia being removed.

In the Head.

a b c d, The lateral dilator of the noſtril and upper lip; *b c*, it's inſertion into the upper lip and noſtril; *d*, it's origin. *f*, The anterior dilator of the noſtril. *g*, The orbicular muſcle of the mouth; *g*, the part belonging to the lower lip: *i*, the part belonging to the upper lip. *l m o*, The long naſal muſcle of the upper lip; *l m n*, the fleſhy part; *m*, it's origin; at *n*, the tendon begins: *o*, the tendon. *p q*, The maſſeter. *r*, Buccinator. *s t*, The broad ligaments of the eye lids. *u w*, The ciliaris muſcle; *w*, it's origin. *x y*, A muſcle belonging, in part, to the alæ narium z, but chiefly to the concha narium inferior; *x* it's inſertion into the alæ narium; *y*, it's origin. z, Alæ narium. &, Septum narium. 2 3, The temporal muſcle; 3, it's inſertion into the coronary proceſs of the under jaw bone. 4, Muſcular fibres which extend and draw outwards the pituitary membrane 5. 5, Membrana pituitaria. 6 7, A muſcle called caninus, or elevator of the corner of the mouth.

9 10, The depreſſor of the lower lip; it ariſes along with the buccinator. 12, The elevator of the chin. 14, Vena angularis. 15, Arteria angularis. 16, A branch of the vena temporalis. 19, The ſalivary duct. 20, The anterior cartilage of the outer ear. 21, The outer ear. 22 23, A muſcle ariſing from the anterior cartilage at 22, and inſerted at 23 into the outer ear. 24, A muſcle which ariſes by two fleſhy heads from the internal ſurface of the anterior cartilage. 25, A muſcle which is a ſort of antagoniſt to that marked 24, 26 *c*, The parotid gland.

In the Neck.

a b c, Sterno maſtoidæus, or ſterno maxillaris; it ariſes from the top of the ſternum at *b*, and is inſerted by a flat tendon into the lower jaw bone, under the parotid gland at, or near, *c*. *d* The ſpungy, fatty ſubſtance of the mane cut directly dowe the middle, and the left ſide remaining on to ſhew its thickneſs. *e*, Ligamentum colli. *f f*, Caracohyoidæus; it ariſes from the upper and internal ſide of the humerus, betwixt the inſertions of the ſubſcapularis and teres major by a flat membranous tendon; and is inſerted into the os hyoides. *g*, Sternohyoidæus. *h i*, Tranſverſalis; *k l*, The tendon of the trachelomaſtoidæus; *l*, a faſcia or membranous part. *m n*, Rectus internus major capitis; *m*, it's loweſt origin from the tranſverſe proceſs of the fourth vertebra of the neck, and the part *p*, of the longus colli. *o*, Inter-tranſverſales minores colli. *p q*, Longus colli. *r s t u w*, Splenius. *x*, Sternothyroidæus. *y*, Hyothyroidæus. z, Cricothyroidæus. &, The lower conſtrictor of the pharinx. 1, Vena jugularis communis. 2, Vena jugularis externa anterior. 3, Vena jugularis externa, poſterior, or ſuperior. 4, Part of the carotid artery, or carotis communis.

Muſcles in the Neck and Trunk, which are inſerted into the Scapula.

a b, Rhomboides; *a*, the origin from the ligamentum colli; *b*, its inſertion, or the part going to be inſerted into the ſcapula. *c d e f*, Serratus minor anticus; *c d*, the fleſhy part ariſing near *c*, from the ſternum, and part of the firſt rib, and is connected to the teres minor by the faſcia *e f*, which is ſent from this muſcle over the infra-ſpinatus ſcapulæ and ſupra-ſpinatus ſcapulæ to its outer edge; *g h i k l o p*, Serratus major anticus.

Muſcles, &c. inſerted into the Humerus and Cubit.

1 2 3 4 5 6, Pectoralis; *a b c d e f*, Supra-ſpinatus ſcapulæ; *h k l n*, Infra-ſpinatus ſcapulæ; *o p q*, teres minor; *q*, its inſertion into the humerus; *r s t u w*, Latiſſimus dorſi.

In the Trunk.

I K L M, Obliquus externus, or deſcendens abdomenis; I, the place where the thickeſt carnous part ceaſes to ariſe from the ribs. K, the ending or inſertion of the carnous part into the tendinous part

In the Right Upper Limb.

NOP Triceps brachii; N, the head, which is called extenſor longus major; O the ſhort head of the triceps, called the extenſor brevis; P, the head called brachialis extenſor longus minor.

The

Anatomy of the Horse, representing the Muscles, Fascias, Ligaments, Nerves, Arteries, Veins and Glands, from Nature. See Farriery.

Wooding sculp.

BRITISH 18 MR 63 MUSEUM

The ſhort head O ariſes from the humerus, the other two from the ſcapula ; its inſertion is into the ancon. QRS, Biceps brachii, or caraco radialis ; Q, the belly of the ſhort head ; R, the belly of the long head ; S, the faſcia of this muſcle, which is ſent down upon the muſcles on the cubit. *aAbcdeegh*, A faſcia or ſtrong membranous production lying over the extending muſcles on the cubit. *f*, The tendon of the extenſor carpi radialis inſerted into the metacarpal bone. *i*, The tendon of the extenſor digitorum communis going to its inſertion into the coffin bone.

1 2, A liga-ment ariſing at 1 and inſerted at 2 *w* ; it helps to bind down the projecting bone of the carpus. 4, The tendon of the profundus. 5, The tendon of the ſublimis. 6, A vein ariſing from under the hoof called vena plantaris externa. 9, An articular ligament. 10, A ligament ſent from the interoſſeus and inſerted into the tendon of the extenſor digitorum communis, which it binds down. 11 12, The horny part of the hoof. 13, A ſubſtance reſembling the villous ſurface of a muſhroom ariſing from the coffin bone, received by the like ariſing from the hoof, which it mutually receives.

In the Right Lower Limb.

*abcc*D*efghikl*, Muſculus faſcia lata; *a*, it's origin from the ilium; *mnop*, Glutæus externus; *m*, a fleſhy origin from the ligament. *q*Q*rst*, Glutæus medius; *qrs*, its origin from the tendinous ſurface of the ſacro lumbalis ; *s*, its origin from the ilium; is inſerted into the great trochanter. *ikluwxyz*, 3 4 5 7 8 9 11, Biceps cruris; 15, The tendon of the plantaris. 16 17 18 19, Semi-tendinoſus; 16, its origin from the ligament which runs betwixt the ſpines of the ſacrum and the iſchium, from the ligament betwixt the ſpinal and tranſverſe proceſſes of the os coccygis; principal inſertion is by a flat tendon into the ſuperior and anterior part of the tibia internally, it is alſo attached to the plantaris near the bottom of its fleſhy part by a flat tendon or expanſion. 22, The large adductor of the thigh. 24 25 26 27 30 31 32 33 34, Ligaments which bind down the tendons, &c. on the tarſus, the inferior and anterior part of the leg or tibia, and the ſuperior part of the metatarſus laterally and anteriorly ; 35, A ligament which binds down the tendons of the flexors. 36 36, Extenſor longus digitorum pedis. 37 37, Peroneus anticus. 38, Flexor digitorum pedis. 39, A branch of the arteria tibialis anterior. 40, Plantaris. 41, Flexor digitorum pedis. 42 46, Vena plantaris externa. 43, Nervus plantaris externus. 44, The interoſſeus, &c. 45, A ligament ſent from the interoſſeus, &c. by which the tendon of the extenſor longus digitorum pedis 36, is bound down, otherwiſe it would ſtart from the bone when the fetlock joint gives much way. 47 48, The horny part of the hoof.

In the Internal Side of the Left Lower Limb.

a, The tendon of the rectus cruris. *b*, Vaſtus internus. *cd*, Sartorius. *ef*, Gracilis. *ghkl*, Semi-tendinoſus; *g*, the fleſhy part; *kl*, the tendon which is inſerted into the tibia at *k*; *m*, Gemellus; *m*, a fleſhy part ; under *n*, lies the tendon over which the tendon of the plantaris is twiſted. *n*, A tendon formed by that going off from the ſemi-tendinoſus at *l*, and by another tendinous faſcia. *opqrs*, The faſciæ which are inſerted into the os calcis gemellus and plantaris ; *t*, The tendon of the plantaris coming from under the faſcias and twiſting over the gemellus at *t* ; *y*, The tendon of the flexor digitorum pedis, the loweſt part of its inſertion is into the ſplint bone. z 1, the tibialis anticus appearing under faſcia. 2 3, The ligament marked 23 24 25 33 36, in this plate of the right leg ; 3 3, its inſertion into the tibia. 4, The ligament marked 30, on the right lower limb in this plate. 5, A ligament which covers the tendon of the tibialis poſticus. 6 7, A ligament ariſing at 7, from the aſtragalus, and inſerted at 6, into a cartilage lying under the tendon of the flexor digitorum pedis. 8 9, A ſtrong ligament which binds the os calcis to the aſtragalus, os naviculare, oſſa cuneiformia, and ſplint bone. 9 9, The articular ligament which binds the tibia to the bones of the tarſus. 10 11, A ligament running over the tendon of the lantaris, inſerted into the ligament 8 9, and ſplint bone. 12, A ſort of ligamentous facia betwixt which and the burſal ligament the mucilaginous glands are contained. 13, The ligament proper to the tendon of the extenſor longus digitorum pedis. 14 15 16 17, The tendon of the extenſor digitorum. 18, Interoſſeus, &c. 19, The ligament marked *d*, in plate the ſecond. 20, A ligament which ariſes from the internal lateral and inferior part of the firſt bone of the toe. 21, Vena ſaphena. 24, Vena plantaris interna. 25 26, The horny part of the hoof. 27, A ſubſtance reſembling the villous ſurface of a muſhroom.

In the Left Upper Limb.

c, Part of the biceps which ſends an expanſion over the bending muſcles lying upon the cubit. *def*, The expanſion marked *mnop*P*qrst*, on the left upper limb in this plate. *gg*, The faſcia marked *a*A*bcdegh*, on the left upper limb in this plate. *h*, The tendon of the muſcle which is analogous to the extending muſcles of the thumb. *iklm*, The ligament marked 16 *hyu*, on the left upper limb in this plate. *no*, A ligament ariſing at *n*, and inſerted about *o*. *p*, The ligament marked 3, on the right upper limb in this plate. *q*, The tendon of the profundus. *r*, The tendon of the ſublimis. *s*, A vein ariſing from under the hoof, called vena plantaris interna. *wx*, The tendon of the extenſor digitorum communis. *y*, A ligament which ariſes from the interoſſeus, &c. *z*, The interoſſeus, &c. 1 2, The horny part of the hoof.

PLATE IV. *Figure* I.—SIDE VIEW.——THE SECOND LAYER OF MUSCLES, WITH THEIR LIGAMENTS, &c.

In the Head.

ab, The elevator of the upper eye-lid. *c*, The lachrymal gland. *d*, The under eye-lid, *ee*, The tarſi ligamentum cilliare, or cilliar edges. *f*, Alæ narium. *ghi*, A muſcle ariſing by a ſmall tendon at *h*, and by a flat membranous tendon at *i*. *k*, The ſeptum narium. *mn*, Caninus or elevator of the corner of the mouth.

o, Orbicularis oris. *pqr*, The depreſſor of the lower lip. *s*, Buccinator. *t*, The anterior dilator of the noſtril. *u*, The elevator of the chin. *w*, The maſſeter. 1, Vena jugularis externa poſterior or ſuperior. 3, Vena temporalis. 4, Vena angularis. 5, Arteria angularis. 10 Glandulæ labiales. 11, The ſalivary duct. 12, The anterior cartilage of the outer ear. 13, The outer ear.

In the Neck.

abcde, Caracohyoidæus. *fg*, Sternohyoidæus. *hik*, Sternothyroidæus ; ariſes from the ſuperior and internal part of the ſternum. *l*, Part of the carotid artery. *n*, The thyroid gland. *q*, The lower conſtrictor of the pharinx. *r*, Hyothyroidæus. *s*, Cricothyroidæus. *t*, Cricoarytenoidæus poſticus. *u*, The inferior maxiliary gland. *wxy*, Rectus internus major capitis, or rectus anticus longus. ABCDEFGH, Tranverſalis cervicis.

I K L, Trachelo-maſtoidæus, complexus minor, or maſtoidæus lateralis. MOPQS, Complexus. U U, Obliquus capitis inferior. W W, Obliquus capitis ſuperior. X Y, Longus colli. 1 2, Branches of the cervical arteries and veins. 3, Part of the jugular vein.

Muſcles on the Shoulder.

ab, The ſubſcapularis, is inſerted into the caracoid proceſs a little below *b*. *cdefgh*, Triceps extenſor cubiti. *iklmn*, Biceps brachii, or rather caraco radialis *s*, Branches of the arteria and vena axillaris. *t*, A branch from the anieria axillaris.

In the Trunk.

abcd, Serratus minor poſticus. *efgh*, &c. Serratus major poſticus. *l*, Serratus major anticus. *m*, &c. *no*, &c. *pp*, &c. Intercoſtals. *stuwxy*, Obliquus internus, or aſcendens abdominis. *xy*, the flat tendon ; that part of the tendon which runs over the rectus is cut off from *t*, to *y*. z, Rectus abdominis.

In the Cubit and Right Upper Extremity.

abcd, Extenſor carpi radialis. *f*, The muſcle which is analogous to the extenſors of the thumb in the human body. *hiklmn*, Extenſor digitorum communis. *ooo*, Ligamentous faſcias. *pqrs*, Extenſor minimi digiti ; *p*, the part ariſing from the ſuperior part of the radius. *tuwxy*z, Flexor carpi ulnaris. 1 2 3, The profundus. 5, Interoſſeus, &c. 6, A ligament from the interoſſeus to the tendon of the extenſor digitorum communis. 8 8, The burſal ligament belonging to the anterior part of this joint. 9, The articular ligament. 10, The tendon of the ſublimis. 12, Vena plantaris externa. The villous covering of the coffin bone is here left on to ſhew it's thickneſs.

In the Right Lower Limb.

abcd, Glutæus medius. *e*, Iliacus internus. *ghik*, Rectus cruris. *nopqrs*, Vaſtus externus. *ruw*, The inſertions of the anterior part of the biceps. *yz*, The inferior ligament of the patella.

1 2, The lateral ligament of the patella. 3 4, The burſal or capſular ligament of the knee. 5, The place where the tendon of the glutæus externus is cut off from it's inſertion. The place where the expanſion is cut off which it ſends to the pyramidalis.

8, The ligament which runs from the ſpinal to the tranſverſe proceſſes of the os ſacrum. 8 9 10; the ligament which runs from the tranſverſe proceſſes of the os ſacrum to the iſchium. 9 11 ; the origin of the biceps from the tubercle of the iſchium. 19 20 21 22 23 24 30, Extenſor longus digitorum pedis. 26, A ligament which binds down the tendon of the extenſor longus digitorum pedis. 27, Extenſor brevis digitorum pedis. 28 ; the tibialis anticus. 31 32 33, Semi-membranoſus ariſing tendinous. 34 35, the inferior part of the ſemi-tendinoſus cut off at 34. 15 36 38 39 ; the large adductor of the thigh.

50 51 52 53, Peronæus. 58 59, Flexor digitorum ; 58, the fleſhy part ; 59, the tendon. 60 61 62 63 64, Gemellus ; 68, 69, the tendon of the plantaris. 70 71, Articular ligaments. 72, A capſular ligament. 74 75, Interoſſeus, &c. 76, Arteria tibialis anterior. 77, A vein from the biceps cruris. 81, A large vein, on which ſeveral valves are marked. 85, The external vena plantaris.

In the Internal Side of the Left lower Limb.

A*a*, The tendinous ſurface of the rectus cruris, inſerted at A, into the patella. *bc*, Vaſtus internus. *d*, The long adductor of the thigh. *e*, A flat tendon or ſaſcia from the large adductor of the thigh. *fg*, Gemellus. *h*, The tendon of the ſolæus. *lmnpr*, The tendon of the plantaris. *uwxyx*, 30, The extenſor digitorum pedis. *x*, The ligament marked 20, in plate the third. 1 2 3, Tibialis anticus. 6, Poplitæus; externally tendinous, particularly near its inſertion. 7, Tibialis poſticus. 8, Flexor digitorum pedis. 9 10, The burſal ligament. 11, The intermuſcular ligament marked 26 on the left limb in this plate.

12 13 14, The internal anterior ligament which binds the patella to the tibia. 15, A membraneous covering of the burſal ligament. 16, The internal articular ligament which connects the os femoris to the tibia. 18, The articular ligament which binds the tibia to the bones of the tarſus. 22 23, The ligament marked 8 9, in Plate the third. 26, The ligament marked 19 in Plate the third. 27, Interoſſeus, &c. marked 18 in Plate the third. 29, Vena plantaris interna. 36, The villous covering of the coffin bone.

In the Internal Side of the Left Upper Limb.

abc, Extenſor carpi radialis. *d*, A ligamentous faſcia. *e*, Profundus. *f g*, The muſcle which is analogous to the extenſors of the thumb. *h*, The tendon of the extenſor digitorum communis. *k*, Arteria brachialis, or the humeral artery. *llmm*, The burſal ligament on the anterior part of this juncture. *n*, Flexor carpi radialis. *o*, Sublimis. *p*, Flexor carpi ulnaris. *q*, Interoſſeus, &c. *s*, Vena cephalica. *t*, Vena plantaris interna. *w*, The villous covering of the coffin bone.

PLATE V. *Figure* I.—THE THIRD LAYER OF MUSCLES.

In the Head.

ab, The globe or ball of the eye; *a*, the pupil; *b*, the white of the eye, or tunica ſclerotica, covered with the albuginea. *c*, One of the lachrymal glands placed in the great canthus of the eye, called carancula lachrymalis and glandula lachrymalis inferior. *d*, The ſemi-lunar fold, formed by the conjunctiva. *e*, Attollens. *f*, Deprimens. *g*, Adducens. *h*, Abducens. *i*, Obliquus ſuperior. *k*, Obliquus inferior. *l*, The trochlea. *m o*, Caninus, or the elevator of the corner of the mouth. *p*, Orbicularis oris, or the orbicular muſcle of the mouth. *q r*, The glandulus membrane which lines the inſide of the lips. *s*, The elevator of the chin. *t u*, The ſhort naſal muſcle of the upper lip. *w w*, Buccinator. *x*, The anterior dilator of the noſtril. *y*, The pituitary membrane on the inſide of the alæ narium. z, The ſalivary duct. 1, Vena jugularis externa poſterior or ſuperior. 2, Vena temporalis. 3, Arteria angularis. 4, Vena angularis. 5, Nervus ſuperciliaris. 10, The anterior cartilage. 11, The ear.

In the Neck.

a, Glandula thyroides. *b c d e f*, The carotid artery. *g*, An artery and vein running over the gula. *i*, OEſophagus. *k*, Trachea arteria, aſpera arteria, or wind-pipe. *l m n*, Sternothyroidæus; *o p*, Crycothyroidæs; *p q*, The lower conſtrictor of the pharynx. *r*, Hyo-thyroidæus, or thyro-hyoidæus. *s*, The lower, and anterior part of the thyroid cartilage. *t u*, Rectus capitis poſticus major; *x w*, Rectus capitis poſticus minor, or rather medius; *y z*, Obliquus capitis ſuperior; A B, Obliquus capitis inferior; C D E F G H I K, Longus colli; L, &c. M, &c. Intertranſverſarii poſteriores colli; N, Intervertebrales. O P Q, The multifidæ of the ſpine. R T U, Spinalis cervicis; 1, Branches of the cervical nerves. 2, Branches of the cervical arteries. 3, Branches of the cervical veins. 4, Part of the jugular vein. 5, Ligamentum colli.

In the Shoulder.

a b, Sub-ſcapularis. *d e f*, Teres major; *g h i k l m*, Longus minor. *n o*, Brachialis externus; *p q*, The inferior part of the ſerratus major anticus. *r*, Nervus cubitalis. *s*, Nervus radialis. *t*, Nervus muſculo-cutaneus. *u*, Nervus medianus. *w*, Branches of the arteria and vena axillaris.

Muſcles, &c. on the Trunk.

1, &c. 2, &c. The external intercoſtals; 3, &c. 4, &c. The internal intercoſtals: *a b c d e f*, The ſemi-ſpinalis and ſpinalis dorſi. *g h i k*, Longiſſimus dorſi; *l m n*, &c, *o*, Sacro-lumbalis. P*p q r s t u*, Tranſverſalis abdominis. *w*, Arteria epigaſtrica, or the internal branch of the external iliaca. *x*, Branches of the nervi lumbares. *y*, The external branch of the outer iliaca. z, Mammaria interna.

In the Right lower Limb.

e f g, The iliacus internus. *h i k l*, Glutæus internus. *p q r s t*, The large adductor of the thigh. *u w*, The gracilis; *u*, the fleſhy part *x y*, Muſculus parvus. 1 2 3 4 5 6, Cruralis. 7 8 9, Vaſtus internus. 10, The lateral ligament of the external ſide of the patella. 11, The middle or anterior ligament of the patella which binds that bone to the tibia. 12, The lateral ligament of the internal ſide of the patella. 13, The burſal ligament of the knee. 14 15 16 17 18 19 20, Tibialis anticus. 23 24 25 26 27, Flexor digitorum pedis. 28 29, Poplitæus. 30, The articular ligament 31, An articular ligament. 32, A ligament which binds the os calcis to the ſplint bone. 33, An articular ligament. 34, Arteria ſciatica, accompanied with a vein. 35 35, Branches of the arteria glutæa. 36, A branch of the arteria obturatrix. 37, A branch of the arteria obturatrix. 38, A branch of the vena cruralis. 39, A branch of the arteria poplitæa. 51, A branch of the vena poplitæa. 52, Arteria poplitæa. 53, Vena poplitæa. 54, Nerves going to the tibialis anticus. 55, Arteria tibialis anterior. 56, Vena tibialis anterior. 57, Glandula poplitæa, commonly called the pope's eye. 58, Vena ſaphæna. 59, The outer cartilage belonging to the coffin bone. 60, The inner cartilage belonging to the coffin bone. 40 41 42 43 44 45 49, The plantaris. 46, A capſular ligament. 47, An articular ligament. 48, A capſular ligament. 49, A ligament which binds the tendon of the plantaris. 50, An articular ligament.

In the Left lower Limb.

a, Arteria cruralis. *b*, Vena cruralis. *h i*, Poplitæus; *k l m n o p*, Plantaris. *q*, A ligament which ariſes from one ſeſamoid bone and runs over the tendon of the plantaris to be inſerted into the other. 1 2 3, Tibialis poſticus. 4, Flexor digitorum pedis, marked 23 24 25 26 27. 10 11 12 13 15 16, Tibialis anticus. 17 18, The internal lateral ligament, which binds the patella to the os femoris. 19 20, The internal lateral ligament. 21 22, The external lateral or anterior ligament. 23 24, The internal, lateral, articular ligament. 25 25, The burſal ligament of the knee. 26, Interoſſeus, &c. 27 28, An articular ligament. 34, The articular ligament of the fetlock joint. 35, The burſal ligament. 36, A burſal ligament. 37, An articular ligament. 38, An articular ligament. 39, Branches of the vena tibialis anterior. 40, A nerve called ſciaticus internus. 41, The inner cartilage belonging to the coffin bone.

In the Right Upper Limb.

a b c, Brachialis internus. *d e f f g h i*, Flexor digitorum profundus. *k*, A ligament which runs down the ſmall end of the ulna. *l m*, Flexor digitorum ſublimis. *n*, Articular ligaments. *o*, Burſal ligaments. *p*, Vena cephalica. *q*, Interoſſeus, &c. *r*, The outer cartilage belonging to the coffin bone.

In the Left Upper Limb.

a b c, Brachialis internus. *d*, Nervus medianus. *e*, Arteria brachialis. *f*, Vena brachialis. *g*, Vena cephalica. *i*, Flexor carpi radialis. *l m*, Flexor digitorum ſublimis; *l*, the fleſhy part; *m*, the tendon. *n o p p*, Flexor digitorum profundus. *q*, Articular ligaments. *r*, Burſal ligaments. *s*, Interoſſeus, &c. *t*, The inner cartilage belonging to the coffin bone.

PLATE VI. *Figure* I. SIDE VIEW — THE FOURTH AND LAST LAYER OF MUSCLES.

In the Head.

a, Muſculus ſeptimus oculi ſuſpenſorius. *b*, Obliquus ſuperior. *c*, The trochlea. *d*, Obliquus inferior. *e*, Attolens. *f*, Deprimens. *g*, Adducens. *h*, Abducens. *i*, The ſemi-lunar fold. *k*, The optic nerve, where the eye is cut away. *lmnop*, The glandulous membrane of the inſide of the lips and cheek. *q*, The elevator of the chin. 1, Vena angularis. 2, Arteria angularis 3, Nervi maxillaris inferioris; they are the third branch of the fifth pair of nerves. 4 5 6, Nervi maxillaris ſuperioris. 7 8 9, The cartilages of the noſe. 10, The anterior cartilage of the outer ear. 11, The outer ear.

In the Neck.

a, Rectus anticus brevis, or minor. *d*, Cricoarytanoidæus lateralis. *e*, Cricoarytanoidæus poſticus. *f*, A very ſmall part of the arytenoidæus. *g h*, Œſophagus. *i k*, The thyroid cartilage. *l*, The annular, or crycoid cartilage. *n*, The ligament by which the thyroid or ſcutiform, and the crycoid or annular cartilages are tied one to the other. *m*, A ligament which ties the lower proceſs of the thyroid or ſcutiform cartilage to the crycoid cartilage. *o*, Trachea arteria, aſpera arteria, or wind-pipe. *p*, The carotid artery, or carotis communis. 1, Arteria carotis externa, or the external carotid. 2, Arteria carotis interna, or the internal carotid. *q*, The trunk of the eighth pair of nerves. 3, A branch of the eighth pair of nerves. 4, Arteria cervicalis, or the cervical artery. 5, Vena cervicalis. *r s*, Rectus poſticus brevis, or internus. *t u*, Intervertebralis. *u w*, &c. The five inferior intervertebrales. *x y*, The multifidus of the ſpine. *z*, One of the ſcalenæ, or rather the elevator of the firſt rib. 1 2 3 4 5 6, &c. 7 8, &c. Ligamentum colli. 13 14 15, The capſular ligament of the articulation betwixt the head and firſt vertebra of the neck. 16, The capſular ligament of the articulation betwixt the firſt and ſecond vertebræ of the neck. 17, Shew the capſular ligaments of the articulations of the five inferior vertebræ of the neck. 18, &c. The vertebral veins, arteries, and nerves of the neck. 19, Part of the jugular vein.

In the Trunk.

a b, &c. The elevators of the ribs. *c*, &c. *d*, &c. Multifidi ſpinæ. *e f*, The lateral muſcle of the tail. *g*, &c. The intertranſverſe muſcles of the tail ariſing from one vertebra, and inſerted into the next, and ſo on through the whole length of the tail. *h*, The ligament which runs over the ſpines of the os ſacrum. *i*, The elevating muſcle of the tail. *k*, The depreſſing muſcle of the tail. *l*, The lungs appearing through the pleura. *m n*, The diaphragm appearing through the pleura. *o*, &c. Nervi intercoſtales. *p*, &c. Arteriæ intercoſtales. *q*, The inteſtines, ſeen through the peritonæum.

In the Right Lower Limb.

a b c, Muſculus parvus in articulatione femoris ſitus. *d e f*, The head of the rectus. *i k l o*, Iliacus internus. *m n o*, Levator ani. *p*, The internal ſphincter ani. *s*, The inſertion of the pectinæus into the os femoris. *t u*, Sartorius. T, A ſort of faſcia under which theſe nerves and blood-veſſels lie. *w x*, The gracilis. z, Part of the adductor of the thigh. 1 2 3, Obturator internus with the gemini. 4, A tendinous faſcia. 10 11, The burſal ligament of the hip joint. 13, Mark where the burſal ligament had its origin from the os femoris, which inſerts itſelf into the patella and tibia. 14, A ligament which binds the cartilage 15, to the tibia. 15, the outer ſemi-lunar cartilage in the joint of the knee.

knee. 18 19, the articular ligament of the knee. 20, A ligament which binds the fibula to the tibia. 21, the external lateral ligament. 22, the internal lateral ligament. 23, the anterior ligament. 24, Part of the tendon of the gemellus. 25, A ſtrong ligament which binds the os calcis to the ſplint bone. 26, the external articular ligaments of the foot. 27, A ligament running from the aſtragalus to the metatarſal bone. 28, Interoſſeus, &c. 29, Iliaca minor. 30, Arteria glutæa. 31, Pudica communis. 32 32, Arteria obturatrix. 33, Arteria cruralis. 34, Vena cruralis. 35, Nervus cruralis. 36, Arteria poplitæa. 37, Vena poplitæa. 38, The outer cartilage belonging to the coffin bone. 39, The inner cartilage belonging to the coffin bone.

In the internal Side of the left lower Limb.

1, The internal lateral ligament of the patella. 2, The internal lateral ligament of the patella. 3, The anterior ligament, which binds the patella to the tibia. 4, The internal articular ligament of the knee joint. 5, A ligament which binds the os calcis to the aſtragalus and os naviculare. 6, The internal articular ligaments of the foot. 7, A ligament which runs from the aſtragalus to the metatarſal bone. 8, Part of the tendon of the gemellus. 9, Interoſſeus, &c. 10, Arteria cruralis, 11, Vena cruralis. 12, The inner ſemi-lunar cartilage in the joint of the knee. 13, The outer ſemi-lunar cartilage. 14, The inner cartilage belonging to the coffin bone.

Muſcles, &c. on the Right upper limb.

a b, Subſcapularis. *d*, Ligaments which bind the orbicular bone to the radius, the bones of the carpus, and metacarpal bone. *e*, Articular ligaments. *f*, Nervus cubitalis. *g*, Nervus axillaris. *h*, Nervus radialis. *l*, Arteria axillaris. *m*, Vena axillaris. *n*, Vena cephalica. *o*, The outer cartilage belonging to the coffin bone.

In the internal Side of the left upper Limb.

a, Articular ligaments. *b*, Interoſſeus, &c. *d*, Arteria brachialis, or the humeral artery. *e*, Vena brahialis, or the humeral vein. *f*, Vena cephalica. *g*, The inner cartilage belonging to the coffin bone.

PLATE II. *Figure* 2.—FRONT VIEW.

THE EXTERNAL MUSCLES, WITH THE MEMBRANA CARNOSA, LIGAMENTS, &c.

In the Head.

a b, The anterior muſcles of the anterior cartilage; *c*, the lateral muſcles of the anterior cartilage of the outer ear; *d*, the origenes: *e*, the inſertion of the middle parts of the retrahens; *f*, muſcles which run from the anterior cartilage to the external ear; *h*, muſcles which ariſe from under the lateral muſcles of the ear; *i*, the lateral depreſſor of the outer ear; *k* K, the epicranius, or muſcle of the ſcalp; *l* 2 *m*, the orbicular muſcles of the eye-lids; L, the corrugators of the eye-brows; *n*, the elevator of the upper lip and corner of the mouth; *o* 3 5, the zygomatici; *p*, the lateral dilators of the upper-lip and noſtrils; *q r*, the orbicular muſcle of the mouth; *s*, part of the latiſſimus colli; *tu*, the tendons of the long naſal muſcles of the upper lip; *w*, the anterior dilators of the noſtrils; *x*, part of the membrana pituitaria.

In the Neck, Breaſt, Shoulders and Trunk.

abcdefghs, The quadratus genæ latiſſimus colli, or broad muſcle of the neck; *ikl*, the proper elevator of the humerus; *nopqr*, the pectoral muſcle; *s*, ſome of the ſuperior parts of the trapezius; *tuwxyz&*, membrana carnoſa.

In the upper Limb.

abcdefghik, The membranous continuation of the fleſhy pannicle down the upper limb, as it covers the muſcles which lie upon that limb.

In the lower Limb.

ABCD*abcdeghik*, The membranous continuation of the fleſhy pannicle down the lower limbs along with the faſcia lata, &c. *l*, The hoof.

PLATE III. *Figure* 2.—FRONT VIEW.

THE EXTERNAL MUSCLES AND LIGAMENTS, THE MEMBRANA CARNOSA, AND FASCIA BEING REMOVED.

In the Head

a, The anterior dilator of the noſtril; *bcd*, the lateral dilator of the noſtril and upper lip; *efgh*, the long naſal muſcle of the upper lip; *k*, Ales naris. *lmno*, A muſcle ariſing by a ſmall tendon along with the long naſal muſcle of the upper lip. *p*, Part of the membrana pituitaria. P, Muſculus caninus, or the elevator of the corner of the mouth; Q, the orbicular muſcle of the mouth; *q*, muſculus ciliaris; *q*, its origin; *st*, the broad ligament of the eye-lids; *uw*, the ball of the eye; *u*, the pupil; *w*, the iris; *xy*, the temporal muſcle; *z*, the maſſeter; 1, arteria angularis; 2, vena angularis; 3, the ſalivary duct.

In the Ear.

ab, A muſcle ariſing at *a* from the anterior cartilage, and inſerted at *b*, into the external ear; *c*, a muſcle which ariſes by two fleſhy heads from the internal ſurface of the anterior cartilage; *d*, a muſcle which is a ſort of antagoniſt to *c*; *f*, the anterior cartilage of the outer ear; *g*, the outer ear.

In the Neck.

abc, Sterno-maſtoideus, or ſterno-maxillaris; *d*, Caracohyoideus; *e*, longus colli; *f*, Scaleni; *gh*, Inter-tranſverſalis minor colli; *iklm*, ſerratus major anticus; *no*, the jugular veins.

In the Shoulders and Trunk.

abc, Serratus minor anticus; *defgh*, Pectoralis; *iklmn*, Supra ſpinatus ſcapulæ; *opq*, Infra ſpinatus ſcapulæ; *r*, Teres minor; *stuw*, Latiſſimus dorſi; *x*, Coraco radialis; *yz*, Triceps brachii; 1, &c. 2, &c. 3456, Obliquus externus, or deſcendens abdomenis; 66, part of its inſertion into the ſpine of the ilium; 77, Longiſſimus dorſi.

In the Upper Limbs.

abcdefghi, A facia or ſtrong membranous production, lying over the extending muſcles which are upon the cubit: *klm*, The tendon *i*, inſerted at *k*, into the coffin bone; *m*, Ligaments which confine the tendon of the extenſor digitorum communis down to the great paſtern; *op*, An expanſion which ariſes from the external articular ligament betwixt the humerus and cubit, and from the olecranon; *qr*, Vena cephalica; *ss*, Vena plantaris; *u*, A ligament proper to the tendon of the extenſor digitorum communis; *wxy*, A ligament whoſe fibres run in a tranſverſe direction over the anterior part of the carpus; *z*, the articular ligaments of the fetlock joint; &, A ſubſtance reſembling the villous ſurface of a muſhroom.

In the lower Limbs.

a, Part of the gluteus externus; *bcd*, Gluteus medius; *efghik*, Muſculus faſcia lata; *lmnopqrst*, Biceps cruris; *uwxz*, 1 2, The tendon of the extenſor longus digitorum pedis; 3, Extenſor brevis digitorum pedis; 4, A ligament common to the extenſor longus digitorum pedis and tibialis anticus; 5, a ligament proper to the extenſor longus digitorum pedis; 6, A ligament common to the extenſor longus digitorum pedis with the tendon of the peroneus: 7, A ligament which binds down the tendon of the peroneus; 8, A ſort of ligamentous facia; 9 10, interoſſeus, &c. 11, the tendon of the flexor digitorum pedis; 12, the tendon of the plantaris; 13, Vena ſaphæna; 14, Vena plantaris externa; 15, Vena plantaris interna; 16, the vena plantaris; 17, the tendon of the gemellus, or tendo achilles; 18, tibialis poſticus.

PLATE IV. *Figure* 2.— FRONT VIEW.

THE SECOND LAYER OF MUSCLES.

In the Head.

a, The anterior dilator of the noſtril; *b c* D, A muſcle which ariſes by a ſmall tendon along with the long naſal muſcles of the upper lip; *d*, orbicularis oris; *e*, canini, the elevators of the corners of the mouth; *f*, the maſſeter; *gh*, the temporal muſcle; *i*, part of the membrana pituitaris; K, the alæ narium; *kl*, the eye ball; *k*, the pupil; *l*, the iris; *mn*, muſculus ciliaris; *m*, its origin; *o*, the elevator of the eye lid; 1 2, nervus maxillaris ſuperior; 3, branches of the nervus maxillaris inferior; 4, arteria angularis; 5, vena angularis; 6, the ſalivary duct; 7, the anterior cartilage of the outer ear; 8, the outer ear.

In the Neck.

ab, Sterno thyroideus; *cd*, caracohyoideus; *f*, Scalenus; *g*, the inferior part of the tranſverſalis cervicis; *h*, the ſuperior part of the tranſveſalis cervis; *i*, part of the trachelo maſtoidæus, complexus minor; *k*, arteria carotis; *l*, part of the jugular vein.

In the Trunk.

abc, Muſculus in ſummo thorace ſitus; *gh*, Serratus minor poſticus; FG, the ſerratus minor anticus. *klm*, &c. Serratus major poſticus; H, Supra-ſpinatus ſcapulæ. I, Infra-ſpinatus ſcapulæ. *nop*, Longiſſimus dorſi. *qrst*, Sacro lumbalis, *yz*, 1 2, The external intercoſtals. 3, Fleſhy fibres which ariſe partly externally, tendinous. 4, &c. Parts of the internal intercoſtals. 5 6 7, Obliquus internus, or aſcendens abdominis. 8 9, Some appearance of the tranſverſalis abdominis. 10, Some branches of the nervi lumbares. 11; the external branch of the outer iliac artery. 12, the external branch of the outer iliac vein. 13, Branches of the arteriæ intercoſtales inferiores. 14, Branches of the arteriæ intercoſtales ſuperiores. 15, Branches of the arteriæ lumbares.

In the Shoulders and Upper Limbs.

A, Nervus muſculo-cutaneus. B, Nervus medianus. C, Nervus cubitalis. D, Nervus radialis. E, Nervus axillaris. F, Vena axillaris. *abc*, Subſcapularis. *de*; the internal part of the pectoralis. *fgh*, Triceps brachii. *iklmn*, Biceps brachii, or rather coraco-radialis. *o*, Part of the brachialis internus. *pqrstuwxy*, Extenſor carpi radialis. *zz*, A ligamentous faſcia. 1 2 3 4 5 6, Extenſor digitorum communis. 7 8, The muſcle which is analogous to the extenſors of the thumb in the human body. 9, Flexor carpi radialis. 10, Flexor carpi ulnaris internus. 12, Vena cephalica. 13, The burſal ligament. 14, The articular ligaments of the carpus. 15, The articular ligaments of the fetlock joint. 16, Vena plantaris.

In the lower Limbs.

abcd, Gluteus medius. *ef* G, Vaſtus externus. *ghik*, Tibialis anticus. *lmnopqrst*, Extenſor longus digitorum pedis. *u*, Extenſor brevis digitorum pedis. *wx*, Peroneus. *y*, Tibialis poſticus. *z*, The tendon of the gemellus. &, The tendon of the plantaris. 1, Arteria tibialis anterior. 2, Vena ſaphæna. 3, Vena plantaris externa. 4, Vena plantaris interna. 5, A ligament proper to the extenſor longus digitorum pedis. 9, A burſal ligament. 7 8, Articular ligaments; 9, the interoſſeus.

PLATE V. *Figure* 2. — FRONT VIEW. —— THE THIRD LAYER OF MUSCLES.

In the Head.

a, The anterior dilator of the noſtril; *ef*, the ſhort naſal muſcle of the upper lip; *g*, the orbicular muſcle of the mouth; *hik*, caninus, or the elevator of the corner of the mouth; *lm*, part of the buccinator; *nop*, the ball of the eye; *q*, one of the lachrymal glands; *r*, the ſemi-lunar fold, formed by the conjunctiva; *s*, attollens; *t*, deprimens; *u*, adducens; *w*, obliquus inferior; *xyz*, Nervi maxillares ſuperiores; 1, arteria angularis; 2, vena angularis; 3, The anterior cartilage of the outer ear; 4, the outer ear.

In the Neck.

ab, Sterno-thyroideus. *c*, Trachea arteria, aſperia arteria, or wind pipe. *defgh*, Longus colli; *ik*, Inter-tranſverſarii poſteriores colli; *m*, nerves coming from betwixt the ſixth and ſeventh vertebræ of the neck; *n*, Arteria carotis; *o*, part of the vena jugularis; *p*, part of the vena cephalica.

In the Trunk.

a, Semi-ſpinalis dorſi; *bcdefgh*, longiſſimus dorſi; *ikl*L, ſacro-lumbalis; *nop*, levatores coſtorum; *qr*, the external intercoſtals; *st*, the internal intercoſtals; *uwxy*, tranſverſalis abdominis; *z*, the elevating muſcle of the tail; 1, the lateral muſcle of the tail; 2, the inter-tranſverſal muſcles of the tail; 3, the depreſſing muſcle of the tail; 4, Branches of the nervi lumbares; 5, &c. branches of the nervi coſtales; 6, branches of the nervi lumbares; 7, ſmall arteries coming out of the ſacro-lumbalis to go to the gluteus medius; 8, Arteries from the intercoſtales inferiores; 9, &c. branches of the arteriæ intercoſtales ſuperiores; 10, the external branch of the outer iliac artery; 11, the external branch of the outer illiac vein.

In the Shoulders and Upper Limbs.

abcde, ſub-ſcapularis; *fgh*, teres major; *iklmno*, longus minor; *pq*, coraco brachialis; *rs*, brachialis internus; *t*, flexor carpi radialis; *u*, the firſt head of the profundus or perforans; *w*, nervus muſculus cutaneus; *x*, nervus medianus; *y*, nervus cubitalis; *z*, nervus radialis; 1, nervus axillaris; 2, arteria axillaris; 3, vena axillaris; 4, Arteria brachialis, or the humeral artery; 5, vena cephalica; 6, burſal ligaments; 7, articular ligaments; 8, cartilages belonging to the coffin bone.

In the Lower Limbs.

ab, Iliacus internus; *cdefghi*, tibialis anticus; *kl*, Flexor digitorum pedis; 1, Arteria tibialis anterior; 2, vena tibialis anterior; 3, the external anterior ligament of the patella; 4, the external lateral ligament; 5, the external articular ligament; 6, a burſal ligament; 7, the external aricular ligament of the tarſus; 8, the internal articular ligament of the tarſus; 9, the articular ligaments of the fetlock joint; 10, the articular ligaments of the great paſtern with the coronary bone; 11, the articular ligaments of the coronary bone with the coffin bone; 12, the anterior part of the burſal ligament of the tarſus; 13, the anterior part of the burſal ligament of the fetlock joint; 14 15, the anterior part of the burſal ligament of the articulation of the coronary bone with the coffin bone; 16 17, interoſſeus; 18, cartilages belonging to the coffin bone.

PLATE VI. *Figure* 2. — FRONT VIEW. —— THE FOURTH LAYER OF MUSCLES.

In the Head.

ab, The glandulous membrane. *c*, The concha narium inferior. *defg*, The four recti muſcles, or muſculi recti of the eye; *h*, obliquus inferior. *i*, Muſculus ſeptimus occuli ſuſpenſorius. *k*, Arteria angularis. *l*, Vena angularis. *m*, The middle portion of the cartilage of the noſe. *no*, The lateral cartilage of the noſe. *pqr*, Nervi maxillares ſuperiores. *s*, The anterior cartilage of the outer ear. *t*, The outer ear.

In the Neck and Trunk.

ab, Inter-vertebrales; *c*, &c *d*, &c. the multifidus of the ſpine; *e*, the elevating muſcle of the tail; *fgh*, the lateral muſcles of the tail or coccyx: *i*, the inter-tranſverſe muſcles of the tail; *k*, the depreſſing muſcle of the tail; *l*, &c. the elevators of the ribs; *m*, arteria cervicalis; *n*, the vertebral vein and artery of the neck; *o*, arteria carotis communis; *p*, the trunk of the eighth pair of nerves; *q*, part of the jugular vein; *r*, arteria mammaris interna.

In the Shoulders and Upper Limbs.

1 2 3 4, Sub-ſcapularis; 5, nervus muſculo-cutaneus; 6, nervus medianus; 7, nervus cubitalis; 8, nervus radialis; 9, nervus axillaris; 10, arteria axillaris; 11, vena axillaris; 12, arteria brachialis; 13, vena cephalica; 14, vena plantaris; 16 16, ligaments which bind together the bones of the carpus; 17 17, &c. articular ligaments; 18 18, cartilages belonging to the coffin bone.

In the Lower Limbs.

aa, Iliacus internus; *b*, interoſſeus, &c; *c*, vena tibialis anterior; *d*, vena ſaphena; *ee*, vena plantaris externa and vena plantaris interna; *f*, a ligament which runs from the aſtragalus to the metatarſal bone; *g g*, &c. articular ligaments; *h*, the outer ſemilunar cartilage in the joint of the knee; *ii*, cartilages belonging to the coffin bone.

PLATE II. — *Figure* 3. — BACK VIEW.

THE EXTERNAL MUSCLES WITH THE MEMBRANA CARNOSA, LIGAMENTS, FASCIA, &c.

In the Head.

A, The outer ear; *ab*, muſcles running from the anterior cartilage to the external ear; 1 2, retrahens; *c*, the ſuperior lateral muſcle of the outer ear; *d*, the lateral muſcle of the anterior cartilage of the outer ear; 3, the inferior lateral muſcle or depreſſor of the outer ear; *e*, the orbicular muſcle of the eye-lids; 4 5 6, part of the latiſſimus colli; *f*, the globe, or ball of the eye; *gh*, depreſſors of the lower lip; *i*, the orbicular muſcle of the mouth; *k*, the elevators of the chin; *l*, caninus, or the elevator of the corner of the mouth; *m*, Zygomaticus; *n*, the lateral dilators of the noſtril and upper lip; *o*, the digaſtric muſcle of the lower jaw; *p*, the inferior maxillary glands; *q*, vena angularis, a branch of the external jugular vein.

In the Neck, Shoulders, and Trunk.

abc, Levator humeri proprius; *def*, the ſuperior part of the trapezius; *g*, the mane; *hiklmnopq*, membrana carnoſa; *r*, the tail.

In the Upper Extremities, or Anterior Limbs.

*abcd*D*efghiklmn*, The membranous continuation of the fleſhy pannicle down the upper limbs; *k*, the internal and external vena plantaris; *mn*, the tendnos of the ſublimis and profundus; *op*, ligamentous fibres which come from the inſide of the radius; *qr*, the horny part of the hoof.

In the Lower or Poſterior Limbs.

AB*abcdefghiklmnopqrstuwxyz*, the membranous continuation of the fleſhy pannicle down the inferior, lower, or poſterior limbs, with the muſculus faſciæ latæ; the faſciæ latæ, and other expanſions of the muſcles, with the muſcles, &c. protuberating under them; 1 2, the horny part of the hoof; 1, the ſuperior part; 2, the ſole or inferior part lying under the coffin bone.

PLATE III. — *Figure* 3. — BACK VIEW.

THE EXTERNAL MUSCLES, WITH THEIR LIGAMENTS, &c. AFTER THE REMOVAL OF THE MEMBRANA CARNOSA.

In the Head.

a, The lateral dilator of the noſtril. *bb*, Muſculi canini. *cdde*, The orbicular muſcle of the mouth. *fgh*, The depreſſor of the lower lip. *i*, Buccinator. *k*, The maſſeter. *l*, Mylohyoideus; *m*, the parotid gland; *n*, the inferior maxillary gland; *o*, branches of the nervus maxillaris inferior; *p*, arteria angularis; *q*, vena angularis; *r*, the ſalivary duct; *st*, vena temporalis; *u*, the outer ear.

In the Neck.

abcd, Coraco-hyoideus: *e*, ſterno-hyoideus: *fg*, ſterno maſtoideus: *h*, rectus internus major capitis: *i*, inter-tranſverſales minores colli: *k*, the tendon of the trachelo-maſtoideus: *lmnop*, ſplenius: *qqrs*, rhomboides: *t*, ligamentum colli: *uwxyz*, ſerratus major anticus: 1, vena jugularis communis: 2, vena jugularis externa anterior: 3, vena jugularis externa poſterior, or ſuperior: 4, arteries coming out of the ſplenius to go to the trapezius and integuments.

In the Shoulder and Trunk.

abcd, Infra-ſpinatus ſcapulæ: *efgh*, teres minor: *ik*, latiſſimus dorſi: I K, triceps brachii; L, part of the pectoralis, which ſends an expanſion down the inſide of the cubit: *lmnop*, obliquus externus abdominis: *q*, the elevating muſcle of the tail: *r*, the lateral muſcle of the tail: *s*, the inter-tranſverſe muſcles of the tail: *t*, the depreſſing muſcle of the tail: *u*, ſphincter externus ani: *w*, acceleratores penis.

In the Upper Limbs.

a, The extenſor digitorum communis: ABCDG*bcddeffg*, an expanſion which ariſes from the articular ligament: E, the tendon of a muſcle: *h*, the tendon of the profundus: *ik*, the tendon of the ſublimis: L, vena cephalica: *m*, vena plantaris externa and vena plantaris interna: *op*, the external articular ligament: *qr*, the internal articular ligament: *st*, a ligament which runs from the os orbiculare to the radius; *uw*, a ligament running from the orbicular bone of the carpus to the falſe metacarpal bone; *uxy*, a ligament which binds down the tendons of the ſublimis and profundus; *z*, a ligament which helps to bind down the tendon of the ſublimis and profundus; 1, a ligament inſerted into the ſeſamoid bones; 2, a ligament ariſing from the upper part of the great paſtern; 3, a ligament which binds the tendon of the profundus to the coronary bone when it is in action; 4 5, the interoſſeus: 6, a ſubſtance reſembling the villous ſurface of a muſhroom.

In the Lower Limbs.

abcd, Gluteus externus: *efg*, gluteus medius; *hik*L*lmnop*, muſculus faſcia lata; OP, the large adductor of the thigh; *qrstuwxyz*, 1 2 3 4 5 6 7 8 9 10 11 12 13, biceps cruris; 14 15 16 17, ſemi-tendinoſus; 18 19 20, the gracilis; 21 7 8, a part of the faſcia lata; 22 23 24 25 26, the tendon of the plantaris; 27, the tendon of the flexor digitorum pedis; 28 29, the tendon of the peroneus; 30, 30, the tendon of the extenſor longus digitorum pedis; 40, extenſor brevis digitorum pedis; 41, Tibialis poſticus; 43, poplitæus, lying under the tendons of the ſartorius and gracilis; 44, ſome of the fleſhy part of flexor digitorum pedis; 45, nerves going to the tibialis anticus; 46, the external nervus plantaris; 47, the internal nervus plantaris; 48, arteria plantaris externa; 49, vena plantaris externa; 50, vena plantaris interna; 51, a ligament which runs from the tibia to the os calcis; it lies over the tendon of the peroneus; 52, the external articular ligament; 53, a ligament which binds together the bones of the tarſus and metatarſus; 54, a burſal ligament; 55, a ſtrong ligament which binds the os calcis to the aſtragalus, os naviculare, oſſa cuneiformia, and ſplint or imperfect metatarſal bone; 56 57, the interoſſeus, &c. 58, a ligament lying over the tendon of the plantaris; 59, a ligament ariſing from the firſt bone of the toe on each ſide; 60, a ligament which binds the tendon of the flexor digitorum pedis; 61, a ſubſtance reſembling the villous ſurface of a muſhroom.

PLATE IV. *Figure* 3.—BACK VIEW.—THE SECOND LAYER OF MUSCLES.

In the Head.

a, Glandulæ labiales: *b*, muſculus caninus: *c*, buccinator: *def*, the depreſſor of the lower lip: *gh*, the orbicular muſcle of the mouth: *i*, the elevators of the chin: *k*, the eye-ball: *l*, muſculus ciliaris: *m*, maſſeter: *n*, branches of the nervus maxillaris inferior: *o*, arteria angularis: *p*, vena angularis: *q*, the ſalivary duct: *rs*, vena temporalis: *t*, the outer ear.

In the Neck.

ab, Coraco-hyoideus: *c*, Sterno-hyoideus: *d* 5, Genio-hyoideus: 6 7, diagaſtricus: *e*, obliquus capitis inferior: *f*, rectus internus major capitis: *ghiklmno* tranſverſalis cervicis: *pq*, trachelo-maſtoidæus, complexus minor, or maſtoidæus lateralis: R *rstuwx*, complexus: *yz*, ligamentum colli; 1, part of the vena jugularis communis: 2, vena jugularis externa anterior: 3, vena jugularis externa poſterior, or ſuperior: 4, branches of the cervical arteries.

In the Trunk.

a, The ſerratus major poſticus; *bcd*, the external inter-coſtals; *e*, fibres which ariſe partly, externally, tendinous, but chiefly fleſhy; *f*, part of the internal inter-coſtals; *g*, fleſhy fibres which run in the ſame direction as the external inter-coſtals; *hiklm*, obliquus internus or aſcendens abdominis; *no*, rectus abdominis; *p*, the elevating muſcle of the tail; *q*, the lateral muſcle of the tail; *r*, the inter-tranſverſe muſcle of the tail; *s*, the depreſſing muſcle of the tail; *t*, the external ſpinctor ani; *u*, acceleratores penis; *w*, glands.

In the Upper Limbs.

ABC, Triceps brachii; *abc*, extenſor digitorum communis; *d*, the tendon of the muſcle, which is analogous to the extenſor minimi digiti in the human body: *defghi*, flexor carpi ulnaris; K *klm*, the profundus; N *no*, the ſublimis; *p*, nervus plantaris; *q*, arteria plantaris; *s*, vena cephalica, it falls into the jugular vein; *t*, vena plantaris externa, and vena plantaris interna; *u*, the burſal ligament; *wx*, the external articular ligament of the carpus; *yz*, the internal articular ligament of the carpus; 1 2, a ligament running from the orbicular bone of the carpus to the ſplint bone; 3 4, interoſſeus.

In the Lower Limbs.

ab, Iliacus internus; *cdefgh*, gluteus medius; AB, gluteus externus; C, gluteus medius; D, pyramidalis; E, muſculus faſcia lata; F, ſartoris; *iklmn* GH, pyramidalis; *o*, triceps ſecundus; *qrst*, triceps tertius; *uw*, gracilis; *xyz*, the inferior part of the ſemi-tendinoſus; 123, ſemi-membranoſus; 45678, veſtus externus; 9, rectus cruris; 10 11 12 13 14 15 16, the gemellus; 18 19, the ſolæus; 20 21 22, the tendon of the plantaris; 23 25 26, flexor digitorum pedis; 27 28 29, peronæus; 30 31, extenſor longus digitorum pedis; 32, extenſor brevis digitorum pedis; 33 34, tibialis poſticus; 35, poplitæus; 36, nervus ſciaticus; 37, nervus ſciatico-curalis; 38, nervus poplitæus; 39, nervus plantaris externus and nervus plantaris internus; 40, a branch ſent from the nervus ſciaticus; 41, nervus ſciatico-peronæus; 42, rami of the ſciatico-peronæus; 43, a branch of the nervus ſciatico-cruralis; 44 45 46, branches of the arteria pudica communis; 46, branches cut off; 47, arteries which go to the biceps cruris; 48, a branch of the arteria poplitæa which goes to the biceps cruris; 49, arteria tibialis anterior; 50, arteria plantaris externa; 51 52 53, branches of the vena hypogaſtrica; 54, a branch of the vena poplitæa; 55, a branch of the vena obturatrix; 56, vena plantaris externa and vena plantaris interna; 57, glandula poplitæa, commonly called the pope's eye; 58 59 60, a ligament running from the ſpines of the os ſacrum to its tranſverſe proceſſes; 61 62, the external articular ligament; 63, a ligament which binds together the bones of the tarſus and metatarſus; 64, a burſal ligament; 65, a ſtrong ligament which binds the os calcis to the aſtragalus; 66 67, interoſſeus.

PLATE V. *Figure* 3.—BACK VIEW. THE THIRD LAYER OF MUSCLES.

In the Head and Wind Pipe.

a, The orbicular muſcle of the mouth: *b*, muſculus caninus, or the elevators of the corner of the mouth and of the cheek: *cd*, the buccinator: *e*, the glandulæ buccales: *fg*, the elevator of the chin: *h*, the globe, or ball of the eye: *n*, arteria temporalis: *o*, arteria angularis: *p*, vena angularis: *qrs*, vena temporalis: *t*, an artery which goes to the glandulæ ſublinguales: *wx*, genio-gloſſus: *yz*, hyothyreoideus: 1 2, the lower conſtrictor of the pharinx: 3 4, hyogloſſus: 5, part of the os hyoides: 6, the outer ear.

In the Neck.
